Workmen often fall foul of one another, and when that occurs they go—to use an auctioneer's phrase—absolutely without reserve. The average workman is a whole-hogger. He LIKES or he LOATHES, with capital letters. He is like a municipal water-cart, which either doesn't water at all and so induces the surface layer of the street to come and lodge in your eye, or else waters so lavishly that the roadway is strewn with profane and prostrated cyclists. When two men of this calibre get at loggerheads with each other, a rumpus of the largest dimensions is usually formed, and you, as the boss, are probably made a Court of Appeal. One man will in gaudy language point out that the other is subverting the discipline of the whole shop. Temporise! Soft soap him! Indicate that you will give the matter your earnest consideration, but that affairs of such magnitude cannot be settled in a moment. And the man will go down to his bench comforted. Probably the other man will also come and give his version. Dose him in the same way. Smother him with soft soap. In two days go and talk the matter over quietly with them if you think it necessary, and tell them what gorgeous fools they made of themselves. Or else let sleeping dogs lie.

You will probably agree with me that engineering is no good unless there is money in it. And you don't get money unless somebody hands it over. The money-shoveller for the firm which employs you is the customer. Now if you are put into contact with the client in the way of business—as, for example, if you become an outside engineer—remember that if you can coax him into paying the firm more than he originally meant to lay out, you are indirectly paying yourself your own wages. It is the man with the smile and the blarney that is sent outside, providing that he knows his business. Lay on the soft soap. Get your man into a good humour, and then come to grips. You will be admired, first, by your employer, next, by your customer, and last, by yourself.—Yours,

THE OLD 'UN.

THE DISTRIBUTION OF MAGNETIC INDUCTION IN MULTIPOLAR ARMATURES.*

BY W. M. THORNTON, D.SC.

The progress of the constructional development of dynamo-electric machines has been characterised by the utilisation of all parts, copper or iron, to their fullest temperature limit, with the result that the weight of a machine for a given output is much less than what it was 10 years ago. A comparison of many machines will, however, show that in one point—the radial depth of the armature core—there is still a wide difference of practice, arising, no doubt, from the fact that there has been little or no direct investigation of the distribution of magnetism within the core upon which to base a scientific treatment.

The most suitable radial depth for the armature core of continuous or alternating current machines can be found by a consideration of the manner in which the induction is distributed from the periphery inwards at a section midway between the poles. This depends upon the pole spacing, the length of the air-gap, the flux density within it, and upon the radial depth of the core. The following investigation is a study of the effect of each of these upon the flux density in the core. For this purpose the magnetic circuit of a multipolar machine was reproduced in miniature (Fig. 1). Each of the four poles could be adjusted by

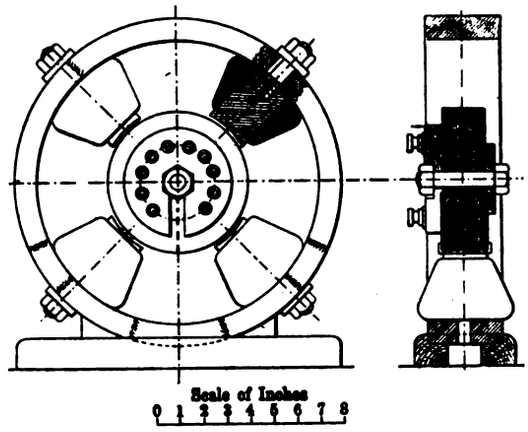

FIG. 1.—Experimental Magnetic Circuit.

means of slots in the cast-iron yoke, and the length of the air-gap varied by thin sheet-iron washers inserted between the pole and the yoke. The pole-tips were well rounded, and the flux density in the gap, as explored by the bismuth spiral, was found to be the same at all parts of the pole-face.

The armature, which in this case was not intended to revolve, consisted of stampings of the usual thickness and 6in. diameter, threaded on a mild-steel bolt. To guard against the distorting influence of the nut and bolt-head, thick hardwood washers were used, so that the magnetic path was confined to the stampings. Along a radius of the core small holes were drilled, and five search coils wound to enclose successive areas at different depths. Each coil had 10 turns of fine double silk-covered wire, with the ends brought to terminals on one of the wooden washers, from which connection could be made to a ballistic galvanometer. The field-magnet windings were of specially insulated wire, and were excited in parallel from large storage cells with a resistance in series with each. The four coils had not quite the same resistance, and the flux densities in each gap were set to equality by adjusting the exciting currents. Once set, the densities remained relatively the same, and

* Paper read before Section G of the British Association at Cambridge, August, 1904.

Digitized by Google

any desired flux density in the gap could be obtained by changing the number of cells. In all the experiments the flux densities in the gaps were tested for equality before each set of readings.

The pole-spacing and air-gap length having been set as desired, and the line of the search coils placed midway between the poles, the cell current was switched on and the magnetisation allowed to become steady. The circuit was then quickly broken, and the throw of the ballistic galvanometer read. The residual magnetism was in all cases too small to be accurately measured by the bismuth spiral, and has not been taken into account in drawing the curves. The error in any case will not exceed 2 per cent., on account of the large demagnetising effect of the gap.

The experiments were divided into three sets. In each the air-gap was kept the same throughout, the pole-pitch and current varied. For each different pitch from four to six readings were taken, with flux densities increasing gradually from 2,000 to 11,000 lines per square centimetre. The results are recorded graphically in Fig. 2. These curves show how the core flux changes when that in the gap is varied.

There are several points of interest which are at once evident. Thus, the depth at which the maximum density is found is *independent of the intensity of magnetisation* except when the air-gap is small and the density great, in which case the maximum is slightly deeper at the higher values. Again, the position of the maximum is *independent of the length of the air-gap*, depending only upon the pole-pitch. The wider the pole-pitch the deeper is the maximum and the greater the flux density towards the centre.

The ratio of the maximum density to that in the gap is *greatest when the pole-pitch is small*, as shown by the following table:

TABLE I.—Ratio of Maximum Core Flux to Flux Density in Air-Gap. Length of Air-Gap, 0·114cm.

Flux density in air-gap.	Angle between centre line of poles.		
	51deg.	65·5deg.	81deg.
3 500	1·28	1·14	0 86
4,000	1·35	1·15	0·92
5,050	1·35	1·19	0·97
6 260	1·37	1·23	0·99
8 500	1·3	1·2	0·96
11,000	1·34	1·12	0·97

There is also a value of the air-gap density for which the ratio is a maximum, in this case a little over 6,200 lines per square centimetre. In other words, there is one particular value of it which makes the core distribution most unequal.

Since the area included between the axes and any curve represents the total induction through the core midway between the poles, it is seen from the curves of Fig. 2 that by reducing the polar arc from 81deg. to 51deg. more lines enter the core (other things being the same) when the air-

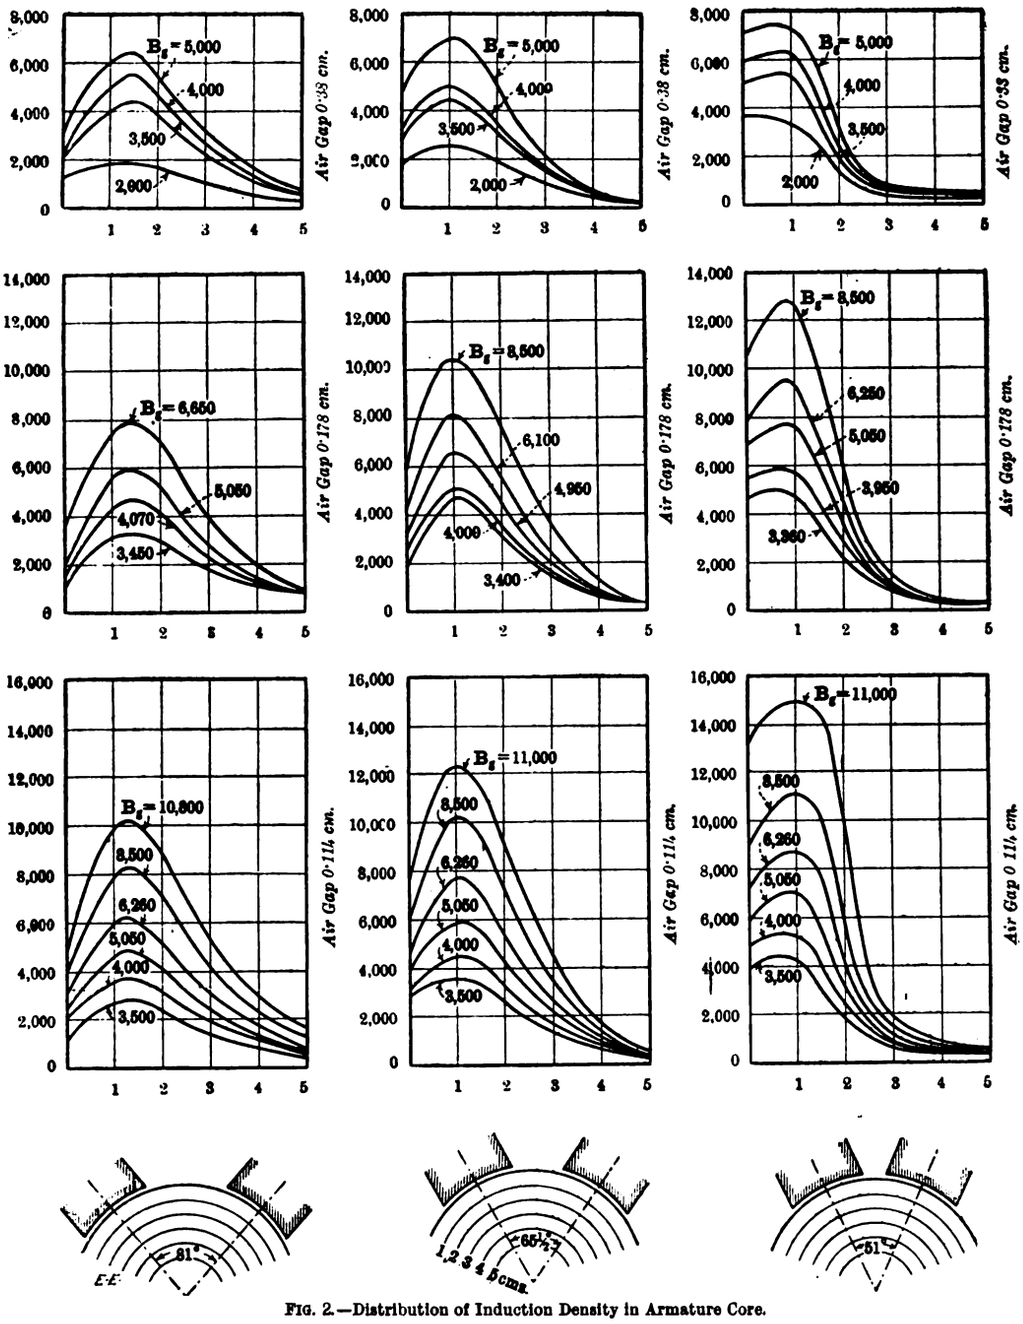

FIG. 2.—Distribution of Induction Density in Armature Core.

Digitized by Google

gap is small, but when it is large fewer lines enter. Thus, with an air-gap of 0·38cm. and a flux density in it of 5,000 lines per square centimetre, reducing the polar arc from 81deg. to 51deg. causes a decrease of 17 per cent. in the total core flux. When the air-gap is 0·178cm. and the flux density the same the reduction is only 2 5 per cent., but with a gap of 0·114cm. and the same flux there is an *increase* of 3 per cent. Raising the flux density to 11,000, the increase with the smallest air-gap is 10 per cent. The flux crossing the air-gap is the same in each case, the change is, therefore, in the leakage. Turning to Fig. 5, the total flux at Section A is 12 per cent. greater than at B. Thus 12 per cent. of the total induction enters the core as a fringe from the pole-tip. That this should increase with

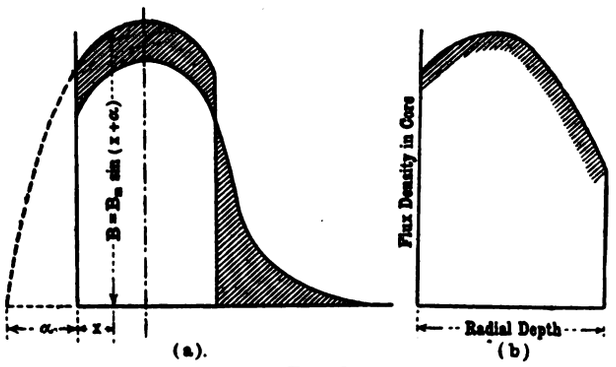

FIG. 3.

the pitch is to be expected, but that it decreases in certain cases points to the conclusion that the reluctance of the outer layers of the iron cannot be neglected in the consideration of core flux. The path through the iron between the pole-tips is four times longer when the pole-pitch is 81deg. than when it is 51deg. The increase in leakage between the poles in the latter case is more than counteracted by the decrease of the reluctance of the core, which permits more lines to enter.

The induction through the inner portion of the core is in all cases low, and where the pole-pitch is small falls off rapidly after the maximum is passed. When the pole-pitch is large the tops of the curves of distribution are nearly

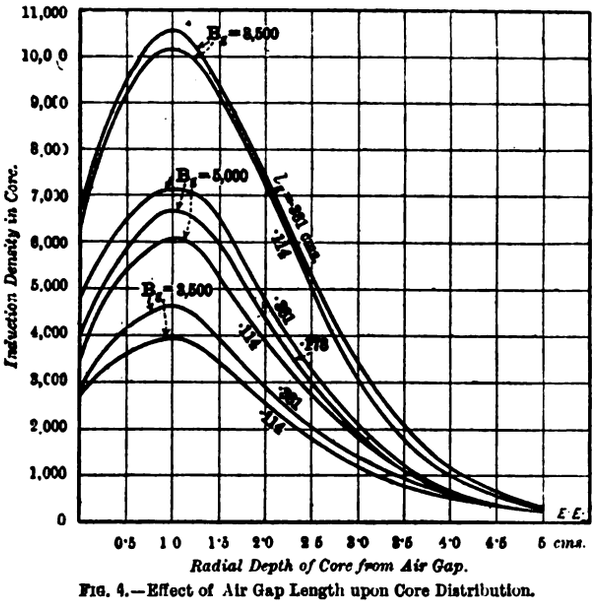

FIG. 4.—Effect of Air Gap Length upon Core Distribution.

sinusoidal, so that by stopping the core at twice the depth of the maximum from the periphery and keeping the total flux the same, the curve of density would be somewhat as follows, Fig. 3A, the portion added being equal to that cut off.

It is not, however, the intermediate but the smallest pole-pitch used in the experiments which corresponds to the usual conditions of practice, the ratio of pole-face to pole-pitch being 0·72. If a straight line is drawn joining the points where the centre lines of the poles cut the armature periphery, it will form a chord whose greatest depth from the arc corresponds with the observed depth of the maximum flux density. In small smooth-core armatures this may be used as a guide to the position of the maximum. The distribution in slotted cores is the subject of an investigation now in progress, but it may be inferred that the maximum will lie not far from the middle of the chord joining the intersection of the centre lines of the poles and the arc through the bottom of the slots. The

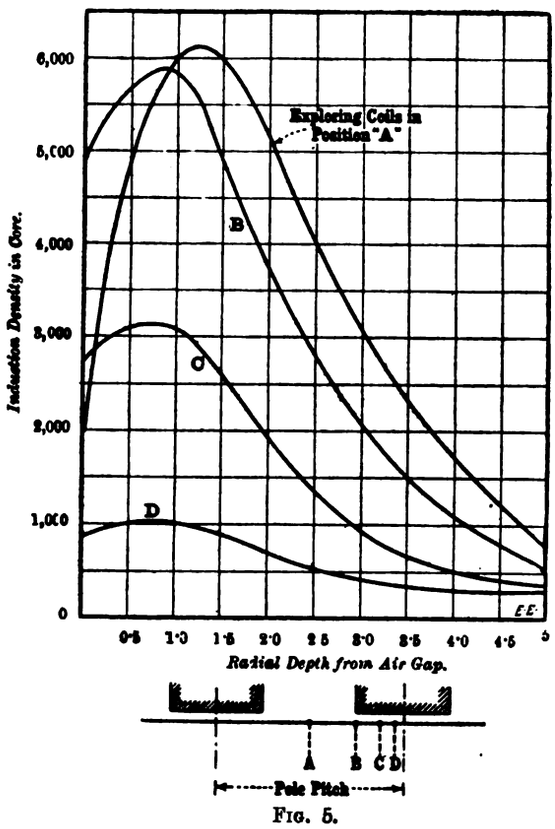

FIG. 5.

curve of distribution will be in general of the form shown in Fig. 3B. To illustrate the importance of this in practice, consider the curve corresponding to a gap flux density of 6,260 lines per square centimetre. In the experimental model the half pole-face is 2·54cm. wide, so that if an average armature flux density is desired equal to 0·7 of that in the gap it is, on the assumption that the flux density is inversely proportional to the area, equivalent to making the core 3·6cm. deep. But by inspection of the curve in the right-hand bottom set in Fig. 2, it is seen that nearly one-half of this depth is inefficient, the two outer centimetres carrying 80 per cent. and 2·5cm. 90 per cent.

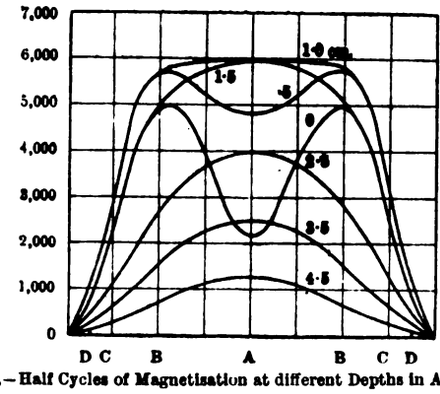

FIG. 6.—Half Cycles of Magnetisation at different Depths in Armature Core.

of the total magnetism. Increasing the radial depth beyond this latter value does not lower appreciably the flux density in the outer portions of the core, the total flux being kept the same.

The path of each line of force is that of least reluctance. There is, therefore, greater concentration along the shortest chord until the permeability there falls, owing to the increased density, and a longer path with higher permeability offers less reluctance. If the ratio, l/μ, remained constant for all lines in the core, there would be uniform flux density over the section midway between the poles. The effect of increasing the pitch of the poles upon the

Digitized by Google

armature distribution can be well seen by comparing curves for the same air-gap and air-gap density in each set of curves of Fig. 2. In the same way, the effect of changing the air-gap can be examined by grouping corresponding curves in each case, as in Fig. 4. One sees that when the gap is long more lines enter the core than when it is short, though the flux density in the air-gap is the same. The total pole-tip fringe must therefore be greater.

The curves so far considered show the distribution midway between the poles, the position of maximum total induction. To examine it between this position and the pole centre line, where, if there is symmetry, the flux density is zero in the core, the latter was moved so that the radial line of the exploring coil occupied in turn the positions A, B, C, D (Fig. 5), and the readings taken as before with the pole-pitch, air-gap, and flux density in the air-gap kept constant. The curves obtained are in Fig. 5. From them one is now able to see how each point of an armature core passes through its cycle of magnetisation. Take, as in Fig. 6, a convenient base to represent the pole-pitch, and mark the positions occupied by the coils. At each of these set up ordinates which are the values of the ordinates of the corresponding curves of Fig. 5, A, B, C, D, at the periphery, and at 0·5, 1·0, 1·5, 2·5, 3·5, and 4·5 centimetres depth. Joining respective points the curves of magnetic change at each depth are obtained. At the circumference there is a large third harmonic, which is also seen with a smaller amplitude at 0·5cm. At 1cm. the curve is flat topped, at 1·5 more rounded, and approximates to a sine wave at 2·5cm.

Both hysteresis and eddy-current losses are affected by the shape of the cyclic curve, but not, according to a calculation, sufficient to appreciably change the efficiency of a machine as compared with that obtained on the assumption of uniform distribution. There will, however, be more heating in the outer layers below the slots; and since deepening the core does not much reduce the outer flux density, the inner layers are positively harmful by shielding the hotter layers from the cooling effect of windage and by acting as a heat reservoir.

The tendency of modern practice to reduce the mass of iron in the armature of both continuous and alternating current machines to a minimum determined only by the local heating is, therefore, in the right direction. The best value for the radial depth becomes then a question of ventilation, especially with armatures of small diameter. Its maximum, consistent with the full utilisation of all the metal in the machine, will be seen from the curves of Fig. 2, taken with an air-gap of 0·114cm. and pole-pitch 51deg., to be about 1·75cm. or 2cm.—that is, from 0·23 to 0·26 of the radius of the armature. Except for considerations of mechanical construction it would be well never to allow the radial depth even of small cores to exceed this. If, however, many of the machines whose details have been published are examined, it will be found that the ratio of radial depth to radius varies from 0·45 in high-speed machines with few poles to 0·08 in very large machines of the flywheel type. In three modern examples of English practice recently published, these values are 7in./37in. = 0·19, 5·7in./16·4in. = 0·35, 7·5in./18in. = 0·42. Mr. E. Kilburn Scott in his paper before the Institution of Electrical Engineers last year gave 0·4 as a suitable ratio for high-speed machines of the first class, 0·26 for the flywheel type with many poles.* Continental practice averages about 0·15 for machines under 1,000 kw.

It is in steam turbo-generators that the ratio is most important, where the diameter of the armature must be kept small and there is more core loss. In Plate XV., sixth edition of Prof. Silvanus Thompson's "Dynamo-Electric Machinery," a Parsons machine is illustrated. In it the ratio of radial depth between slots and ventilation holes to the radius is 0·45. Here, however, the pole-pitch is 90deg., and the pole-face only 53·5 per cent. of the pole-pitch. The conditions are then nearer to the middle set of curves of those obtained with 0·178cm. air-gap in Fig. 2. From these it is seen that the core might be stopped with advantage at about 34 per cent. of the radius. Considerations of rigidity and mechanical construction are, however, in these machines of the first importance.

It is proposed, further, to examine the influence of current in the armature conductors upon the distribution of magnetism in the core with different air-gaps, and under all conditions of excitation.

TRADE NOTICES AND NOVELTIES.

"Tetrad" Trolley Ears.

Through the courtesy of Messrs. William C. Yuille and Co., of 17 and 19, West-street, Tradeston, Glasgow, we are able to illustrate this week the new "Tetrad" trolley ears which this firm are putting on to the market. It will be seen from these illustrations that the trolley ear in question is a radical departure from the ordinary type now in general use. The characteristic difference is that with the "Tetrad" ear the trolley wire is inserted in the upper part of the ear instead of into a groove in the lower part, as is the case with the ordinary type. In consequence of this the trolley wheel runs on the metal of the ear itself, and not on the exposed surface of trolley wire and solder, as is ordinarily the case. The details by which this is possible are seen in the accompanying illustrations. It is claimed for these ears that they will outlast three renewals of trolley wire, and that they are much more durable than the usual soldered ear. It is also claimed, and we think rightly, that they are more easy to erect and adjust. The ear also always presents a uniform and even surface to the trolley wheel, which tends to do away with the bumping frequently experienced at the points of support and the consequent undue wear. We shall await with interest the results of practical trial with this new construction of supports for overhead trolley wires.

MIDDLESBROUGH DOCK ELECTRIC AND HYDRAULIC POWER PLANT.*

BY VINCENT L. RAVEN, MEMBER, CHIEF ASSISTANT MECHANICAL ENGINEER, NORTH-EASTERN RAILWAY.

(Concluded from page 456.)

The electrical switchgear presents many points of interest. It consists of a controller with magnetic blow-out, and with overload release gear. The controller is worked by a pedal projecting above the capstan case by about 4in. This pedal is removed when the capstan is out of use. The pedal is connected to a dash-pot which prevents the controller being operated too rapidly when a driver is starting the capstan, but at the same time, by means of valves in the plunger, allows the controller to return rapidly to the off position. The return to the off position is effected by means of a weight, which is lifted as the pedal is depressed. In the event of the capstan being pulled up by sudden overload, the release gear works instantaneously and breaks the main circuit. Upon the pressure being removed from the pedal, the return of the controller to the off position automatically replaces the release switch, and the capstan is ready to start again. The whole of the gear is contained in a watertight cast-iron case sunk in the ground, the top of which consists of chequered plates flush with the quay-side. The trials of these capstans are shown on Table 3.

Cables.—The distribution of current is effected by a network of feeders and distribution cables laid below ground. These cables are fibre-insulated and lead-sheathed; they are laid in wooden troughs on the solid system, and are at a depth of about 2ft. from the surface. Watertight junc-

tion boxes are provided at the junction of the feeders. The crane connection boxes are in two portions, the bottom of which contains the positive and negative distributing cables, and the top the connection apparatus for the cranes. The connection socket consists of a circular gunmetal hood, which accurately fills the aperture in the cover of the box, and is so shaped as to shield the joint from wet. The interior of this hood contains two gunmetal tongues which meet the two clip contacts in the interior of the box. A stud and groove ensures that the socket shall enter the aperture only in the correct position. The flexible crane cable enters the hood of the socket through a trumpet mouth, and the whole apparatus is shaped so as to obstruct the quayside as little as possible. There are 52 boxes in all, placed 20 yards apart. They have withstood the test of the severest weather, and have given no trouble. The cost of cables complete is only about 50 per cent. of the cost of hydraulic mains for the same power.

Lighting.—About half a mile from the power station a sub-station, fitted with switchboard for the lighting, has been put down. There is only one cable for supplying the power both for the electric machinery and the lighting of the docks, offices, and station.

Summary.—The traffic department (see Table 4) find the electric cranes to be a great advantage. There is very little time required for oiling, as the crane has ring lubricators to all main bearings, and the wheels run in oil baths, which only require attention about once a month. The oil bath effectually prolongs the life of the wheels and deadens any noise, which is a great advantage to the drivers in hearing instructions. The controlling of the crane by one handle is also a distinct advance both over the steam and the hydraulic cranes. With the steam cranes the driver had to attend to four levers and a foot-brake, in addition to the feed pump and the firing of the boiler. In the case of the hydraulic crane two levers are in use, which require considerable force. The automatic cut out in the electric cranes cuts off the current in one case at 3 tons 5cwt. and the other at 10 tons 10cwt, and this device prevents an overload upon the crane. Should the current fail at any time the brake on the lifting gear is applied automatically, and will hold the full load in any position with safety. To obtain some definite idea of the speeds of the various cranes when working under ordinary conditions they were tested separately. The steam crane had a load of two tons put on, and this was lifted

* This figure represents the load factor in proportion to the three electric engines working at maximum speed.

30ft, slued through 106 5ft., lowered 30ft., light hook lifted 30ft., slued 106·5ft., and light hook lowered 30ft. The total time for these operations was 1 minute 44 seconds, or at the rate of 34 cycles per hour. The hydraulic cranes, under precisely the same conditions, occupied 1 minute 40 seconds per cycle, or equivalent to 36 cycles per hour. The electric cranes did the same work in 64 seconds per cycle, or 56 cycles per hour, and this is capable of being increased beyond even this point with a good driver. Therefore, in ordinary working the electric cranes are doing 50 per cent. more work per hour than the hydraulic or steam cranes. On actual test it was found that the electric cranes can be released from the rails, travelled 30ft and refixed to rails in three minutes. When it has been necessary to move the hydraulic cranes to suit the working into the various ships' holds, six men have had to be called one hour earlier in the morning to set the four cranes which are required for each vessel. With the electric cranes the men have not to be called earlier, as two men in summer and four in winter can disconnect and connect up four cranes in 15 minutes. In winter, on frosty nights, four men have been employed six hours each for the purpose of keeping fires to prevent water in the cylinders of the hydraulic cranes from freezing; on the other hand, the electric cranes have no need of this. When a steam crane had to be got ready for work, the driver had to commence one hour earlier in order to obtain steam, whereas the hydraulic and electric cranes are ready for work at any moment. In 1903, when the steam cranes were superseded by the electric cranes, the quantity of traffic dealt with at this dock was:

	Tons.
Coal and coke exported	259 746
Merchandise exported	297,304
Merchandise imported	33,696
Total	590,746

To do this work, the quantity of coal burned at the new power station, which, as previously stated, supplies both the electric power, lighting, and hydraulic power water was: 3,428 tons 4cwt., or the total merchandise worked per ton of coal burned was 172·3 tons, or a gain of 47·2 per cent.

THE DOG AND THE BONE.

Once upon a time there was a station engineer who, being dissatisfied with his lot under a company, cast around to see how he might increase his banking account, and also how he might become boss in his own department. For he objected to being under a board of inquisitive directors, and having to render account to a stupid secretary, none of whom understood the meaning of Ohm's law. So he answered an advertisment from a borough council, and, lo and behold, he was surprised and overjoyed to receive a summons to appear before the committee. And having answered all their questions satisfactorily he was duly appointed, and it gave him pleasure to shake the dust of the company's service off his feet and to feel that at length he was a public servant and master in his own house.

And being with the borough council but a short time, the engineer discovered that there were many tendings towards Socialism in the district, but he would have none of this amongst the men he employed. Now of all these, none was more insistent on the rights of the poor British working-man than a certain navvy whose function it was to dig hard all day to make trenches for the cables that convey the current. And so the engineer, having found the navvy many times addressing his fellows to the neglect of the work, for which he paid them the wage as fixed by the union, presented him with the sack and told him to come back no more.

Now about this time it befell that the local elections were about to take place, and the engineer saw the navvy ofttimes addressing the crowds; but he scoffed and passed by, taking no interest in the whole affair. But, to his great surprise, he found that the navvy had been elected a councillor, and later on when he appeared before his committee, behold, the navvy likewise had a seat at the table. Then the engineer felt passing sore within himself, and this feeling was in no wise removed when he found that the rest of the committee were also Socialists. And when with one accord they all wanted to know why the wheels went round, and whether it could not be done more cheaply, the spirit of the engineer waxed obstinate, and he said unto them, "Have you not engaged me as engineer, and do I not know best about all these things?" Then

Digitized by Google

arose the navvy and said, "Oh, councillors, this fellow speaks not the truth when he says we have appointed him; but as he is contumacious, let him say that we have discharged him. Therefore I move that he receive three months' notice from this day." And the motion was carried with only two dissentients.

Moral.—You never know when you are well off; also, you may be entertaining a king unawares.

LEGAL INTELLIGENCE.

AN ELECTRICAL COMPANY'S AFFAIRS.

In the City of London Court on Friday last, his Honour Judge Rentoul, K.C., heard an action brought by Mr. J. W. Record against Brooker and Goss, Limited, electrical engineers, 50, Broad-street House, E.C., to recover £19. 4s. 6d. wages and commission. There was a counterclaim for £50.

Mr. Owen Thompson, plaintiff's counsel, stated that the defendants were seeking to enforce specific performance of a contract for the plaintiff to take 50 shares in the defendant company, representing the qualification for a director. As a matter of fact, shares were allotted to no one, because the company proved entirely abortive, but now, after 18 months, the defendants were attempting to compel the plaintiff to take up 50 £1 qualification shares, although they had never been issued. The plaintiff was employed by Brooker and Goss in 1902, before the business was converted into a company. He had a salary of £2 a week, and 1¼ per cent. bonus on all instruments calibrated in the plaintiff's department. A new agreement was made by which his salary was raised to £2. 5s. a week, and from Jan. 1 there was an agreement that it should be raised to £2. 10s. a week. That had not been paid. During the last part of the time while the plaintiff was working for the defendant company he only received a portion of the salary, and some weeks it was as little as 10s. The plaintiff gave notice to leave, but he stayed on and worked until Aug. 6. He was now, however, compelled to sue for his wages. The company was incorporated on Feb. 18, 1903. The first directors were Mr. Brooker, Mr. Goss, Mr. Cruttenden, and the plaintiff. They all signed a consent to act as directors as required by Section 2 of the 1900 Act, and the plaintiff acted for a short time. Mr. Thompson further stated that the plaintiff joined the company on the first prospectus, which was subsequently altered, and the terms on which the shares could now be issued were entirely different. At the end of two months, the statutory limit for acting as a director without taking up the qualifying shares, the plaintiff ceased to be a director, and became a paid electrician simply.

Mr. Brooker, on behalf of the defendants, said the plaintiff was never engaged at £2. 10s. a week definitely, but only provisionally.

His Honour gave judgment for the plaintiff on claim and counterclaim, with costs.

COMPANIES' MEETINGS AND REPORTS

DICK, KERR, AND CO.

The ordinary general meeting was held on Tuesday at the Cannon-street Hotel, Mr. John Kerr, M.P. (the chairman of the Company), presiding. Particulars of the report for the year ending June 30 were published in our last week's issue.

In moving the adoption of the report, the **Chairman** alluded to the Company's policy in making ample allowance for depreciation. Proceeding, he remarked that, beside the Far East and India, Australia, South Africa, Canada, and Argentina had proved good customers. Europe and America were practically closed markets owing to the protective tariffs, for which the chairman stated he attached small blame to those countries. Having referred to the successful outcome of the Company's contract for electrifying the Liverpool-Southport branch of the Lancashire and Yorkshire Railway, the chairman remarked that there was a possibility of considerable development in this direction in the near future. The Company had no apprehension in regard to competition from foreign or other rivals; they were closely studying every possible means of reducing cost of manufacture without lowering the high standard the Company had always aimed at. In conclusion, he paid a tribute to the services of the staff and workmen.

The report was unanimously adopted.

Messrs. D. C. Ellis and G. Richardson, the retiring directors, were re-elected; also the auditors, Messrs. Gane, Jackson, Wells, and Co.

The proceedings terminated with a cordial vote of thanks to the directors.

MERSEY RAILWAY.

The half-yearly meeting was held on Tuesday, Mr. James Falconer presiding.

The **Chairman** said the accounts for the half-year showed a substantial improvement, but the Board were by no means satisfied that they had reached anything like a final conclusion. The number of passengers carried, excluding season-ticket holders, had increased 1,300,000, or nearly 40 per cent., and the receipts had increased by £7,579, or 29 per cent. In considering the effects of the change from steam to electricity, and comparing the half-year with the corresponding half-year, it was necessary to take into account the fact that they had given the public a greatly improved service, and for the increased expenditure of £1,530 (without taking into account the exceptional charges for pumping and ventilation) they had practically doubled the working of last year. The train mileage was 411,683 against 218,308—that was to say, the Company had doubled the facilities for the travelling public. The cost per train mile formed a proper basis for comparing the cost of steam traction and electric traction, and in that respect the figures were very striking. During the half-year ended June, 1903, steam was used for four months and electricity for two. A comparison of the cost per train mile during the period of the half-year under review showed that cost had decreased from 30·1d. to 17·35d., or a reduction of 42 per cent.; while if including the exceptional charges mentioned, the decrease was from 35·25d. to 19·58d.—a very striking reduction arising from the change. These figures conclusively established the extraordinary superiority of electrical traction over steam in dealing with such a railway as theirs. The cost per train mile at which the existing traffic had been carried practically represented also the cost at which they could carry double the traffic. They had now reached the point of earning power per train mile of something like 2s., and the future of the railway depended upon increasing that figure by doing everything possible to give confidence to the public, and by affording every facility desired.

Replying to a shareholder, the **Chairman** said that roughly the revenue was now £80,000, and whenever it exceeded £130,000 payment on the ordinary stock would begin. If the revenue were doubled, there would practically be £30,000 for distribution to ordinary stockholders.

The report was adopted.

WILLANS AND ROBINSON.

In submitting the accounts for the half-year ending June 30, the directors of Willans and Robinson, Limited, deeply regret that the results are so unfavourable. Apart from losses at Queen's Ferry, which, under the circumstances, were inevitable, the Company's operations at Rugby have, for the first time in its history, resulted in a loss. After making a somewhat increased allowance for depreciation, amounting to £7,601, there is a loss of £3 345 in respect of Rugby. The loss at Queen's Ferry, after writing off £9,937 depreciation, is £25,902, and there is, further, a debit balance of £7,932 brought forward from the preceding half-year. The loss at Rugby is attributable chiefly to the extreme badness of trade, under the stress of which orders are taken by many firms at prices which make profit impossible. As they have before explained, the directors have striven to open up new branches of business, with a growing success upon which they found strong hopes for the future, but such work cannot yield a profit at first, and, in fact, in its initial stages it is bound to be a source of loss. This affects not only the half-year under consideration, but also the current half-year, and probably the next half-year as well. Nevertheless, the directors are satisfied that in developing these new branches of work, of which steam-turbines and gas-engines are the chief, they are taking the surest course for the ultimate revival of the Company's prosperity. They are also endeavouring to economise in every way, and have effected large reductions in expenses, though the evidence of this will not be apparent until the accounts of the current half-year are presented. The utmost is being done to maintain the reputation of the Company for excellence of manufacture, and to keep the Willans engine in its old position of supremacy. In their efforts to this end the Board feels that it is greatly strengthened by the additions made to it last spring. It is not possible to operate the Queen's Ferry works upon a sufficiently large scale to make a profit, or even to pay expenses, without raising more capital for plant and for working. This is out of the question at present, and therefore the works are kept employed only to the extent necessary to complete one important contract. While the works are thus maintained as a going concern (except the steelworks, now closed, but capable of being readily restarted), the directors are endeavouring to find a purchaser for them—subject, of course, to the assent of the trustees for the debenture-stock holders. Negotiations to this end are in active progress. The increased loss at Queen's Ferry is largely due to the increase in depreciation (£2,688 more than last half-year). An unexpected source of loss has also arisen in the necessity for rejecting, and valuing only as "scrap," a quantity of material made in the earlier stages of the work, and believed at the time to be satisfactory. This source of loss is not likely to recur, but under present conditions at Queen's Ferry some loss cannot be avoided, even if the works be closed entirely. Everything that is possible is being done to reduce expenses and to increase efficiency. The directors have given constant attention to the improvement of the financial position of the Company, which is the dominant factor in the situation. New business, and even the best-founded hopes of future profits, will be fruitless unless the Company can pay its way and has working capital at command. The directors are glad to say that the financial position during the past few months has much improved. Money has come in comparatively freely from debtors, and shares in other companies (received in part payment under contracts) have been sold at favourable prices. The debt to the bank has been paid off, and an ample balance created, without selling the whole of the reserve fund investments; investments remain at this date which, at cost, represent £27,053. The loss upon realising the securities sold at the present low prices has been charged against the reserve fund account, which has also been debited with an amount written off from other investments of the Company, which the directors have rigorously valued down to what they believe to be thoroughly safe figures. The opinion was expressed at the last meeting that the remuneration of the additional directors should be provided by deductions from the salaries of the existing directors. As the directors are remunerated under separate agreements for service, and not collectively, this question, as was

Digitized by Google

explained at the meeting, could only be dealt with by the directors individually, and not by the Board as a whole. Mr. Robinson and Sir Gilbert A. Clayton East accepted reductions as from March 31 last, equivalent to their *pro rata* proportions of the new directors' salaries. Mr. Arthur Lazenby expressed, and still desires to express, his willingness to follow the same course; but, at the wish of some of his colleagues, he has deferred action until they could bring the matter, as affecting him, before the shareholders at the ensuing meeting.

SOUTH LANCASHIRE ELECTRIC TRACTION AND POWER.

The shareholders have received notice of an extraordinary general meeting to be held on Oct. 7 for the purpose of considering the advisability of winding-up the Company, in view of its contemplated reconstruction, and, if thought fit, passing a resolution for voluntary winding up, and the appointment of a liquidator. The accounts of the Company for the year ended June 30 show a profit of £2,573, making, with the balance brought forward, £3,351, but liabilities to contractors for works not certified by consulting engineers, and the accrued dividends from date of allotment to June 30, 1904, on the preference shares have not been provided for. There is also a debit in the accounts of £58,702, being interest on debenture stock and calls paid in advance for the two years ended June 30, 1904, less credit interest of £12,347. The directors report that the whole of the tramways and light railway constituting the first constructional scheme of the Company have been in operation since Easter, 1903 (portions of the scheme being in operation earlier), but the receipts on the working of these lines have not quite come up to expectations. It must be remembered, however, that the districts served have passed through a crisis in the cotton industry, and that trade generally has been extremely depressed, and certain sections which would no doubt form valuable feeders have not been constructed. The arrangements for raising further capital, which were sanctioned by the debenture stockholders and authorised by the shareholders at the latter end of last year, were actively proceeded with by the directors, who were, however, frustrated largely owing to the financial depression, and on an application by a debenture-holder the Court appointed receivers and managers. Negotiations are pending, however, and there is reason to hope that a scheme of reconstruction will be practicable, and that the additional capital required to proceed with the construction of the lines may be obtained at a satisfactory rate. Sir John A. Willox, M.P., has, through continued ill-health, retired from the directorate, and Mr. Joseph Beecham and Mr. H. R. Hogg have joined the Board. The Hon. Arthur Stanley, M.P., and Mr. C. E. Maples offer themselves for re-election.

PERSONAL.

The Caerphilly District Council have appointed Mr. A. H. Preece as the electrical engineer.

The Luton Town Council have increased the salary of the electrical engineer from £204 to £250 per annum.

We note that the borough engineer of Ealing, Mr. J. Douglas Knight, M.I.E.E., has this week returned from his visit to America.

The Willesden District Council have appointed Mr. John Geo. Bruce, assistant distributing engineer to the St. Pancras Borough Council, resident electrical engineer.

The Huddersfield County Borough Council have appointed Mr. R. H. Wilkinson, Oldham, general manager and engineer of the tramways at the salary of £350 per annum.

The Portsmouth Town Council have increased the salary of Mr. Foale, the engineer and manager of the electric lighting station, from £325 per annum, as at present, to £400 per annum.

The Blackburn Electricity Committee have accepted the resignation of the borough electrical engineer, Mr. A. J. Giles, as he has been offered an engagement abroad at a salary of £1,800 per annum, more than twice that now received for his present office.

Mr. Bertram S. Giles, M.I.E.E., who was for many years responsible for the design of Messrs. Mather and Platt's electrical machinery, and acted as their technical representative and adviser, has now joined Messrs. Johnson and Phillips as manager of their electric light and power works.

Mr. John McMillan, resident electrical engineer to Falkirk Corporation, has been presented with a handsome silver tea service, a silver tea caddy, and a silver-mounted tea tray by the senior burgh officials as wedding gifts. Mr. A. Balfour Gray, town clerk, presided over the presentation, which was made at the burgh buildings by Mr. Wm. McCrae, gas manager.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Buenos Ayres.—The Municipality of Chivilcoy require tenders for installation of electric lighting.

Salford.—The Electricity Committee invite tenders for paper-insulated cables. Tenders to the Town Clerk by Oct. 6.

Crejour (Roumania).—The Municipality require tenders for construction and working of tramways for 50 years by Nov. 7.

Pretoria.—The Commanding Royal Engineer at Army Head quarters, Pretoria, is calling for tenders for the electric lighting of cantonments.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Blackheath.—The County Council require tenders for electric wiring and fittings, etc., at the ranger's house. Tenders by Oct. 11. See advertisement.

Mexico.—The Federal District Railway Company of Mexico require tenders for the electrification of six tramway lines in the town. Applications are to be made direct.

Wandsworth.—The Borough Council require tenders for electric lighting and ventilation of Council House. Tenders by Oct. 18. Full particulars in advertisement columns.

Espinar (Spain).—The Municipality require tenders for construction and working of an electric tramway for 20 years. Particulars from the Alcalde. Tenders by Oct. 12.

Pangbourne.—Tenders are required for lighting the village during the coming winter, for the Pangbourne Parish Council. Particulars may be obtained of Mr. C. West, jun., clerk.

Great Western Railway.—The Directors of this Company are prepared to receive tenders for the supply of various stores from Dec. 1 next to Nov. 30, 1905 Tenders by Oct. 17. See advertisement.

Almendralejo.—The municipal authorities require tenders for the electric lighting of the town for 10 years. Particulars may be obtained from the Alcalde of Almendralejo, province of Badajos, Spain. Tenders by Oct. 13.

Ilford.—The Urban District Council invite tenders for the supply and erection of balancer and switchboard panel, and reversible traction booster and switchboard panel. Tenders by Oct. 4. See advertisement.

Canterbury.—The Drainage Committee invite tenders for electric light fittings in the engine-house at the sewage farm. Particulars may be obtained of Mr. Arthur C. Turley, A.M.I.C.E., city surveyor, Guildhall-street, Canterbury. Tenders to the Town Clerk by 10 a.m. on Oct. 3.

Cumberland and Westmoreland Lunatic Asylum, Carlisle.—Tenders are required for plant. Copies of tender may be inspected at the office of the Consulting Engineer, Electricity Works, Northallerton, Yorks. Tenders to the Clerk to the Committee of Visitors by Nov. 1.

Weymouth.—The Town Council invite tenders for the wiring of 12, Gloucester-row, in accordance with specification and conditions which may be seen at the offices of the Borough Electrical Engineer, Sunnybank, Westham. Tenders to the Guildhall, Melcombe Regis, by 3 p.m. on Oct. 3.

London, S.W.—The London County Council invite tenders for the manufacture, delivery, and erection of three electric car traversers at certain of the Council's tramway depôts in the South of London. Specification, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Rochdale.—The Tramways Committee require tenders for the wiring of car depôt. Applications, with £1. 1s. deposit, to Mr. C. C. Atchison, borough and tramways electrical engineer, Rochdale. Extra copies 5s. each. Tenders, endorsed "Car Depôt Wiring," to be addressed to the Town Clerk, Town Hall, Rochdale.

Rochdale.—The Corporation invite tenders for the supply, delivery, and erection at the electricity works, Rochdale, Lancs., of three ejector condensers, three electrically-driven circulating pumps, and the necessary extensions of the steam, exhaust, and water pipes, valves, and accessories. Tenders by Oct. 10. See advertisement.

Philippopolis (Roumelia).—The Municipality requires tenders for a concession to construct and work electric lighting and tramways for 50 years. A guarantee of £6,000 is required. Tenders by Oct. 15. On the next day a second adjudication will take place in case there is an offer of £5 per cent. less per kilowatt-hour than the minimum.

Tschatschak (Servia).—The Electricity Company Owtschar und Kablar in this town require two turbines of 750 h.p. each, two generators for three-phase currents, and other plant for the erection of a hydro-electric central station, and equipment of lines of distribution within 40 miles, by Oct. 2. Specifications, etc., may be obtained from the Manager of the Company.

Craivo (Roumania).—The *Moniteur des Intérêts Matériels* (Brussels) announces that the adjudication will take place at 4 p.m. on Oct. 25 (Nov. 7) at the Mayoralty of Craïova, of the concession for construction and working of a line of tramways (mechanical traction) in the town of Craïova. The duration of the concession is fixed at 50 years. A provisional deposit of £200 is required.

Manchester.—The Electricity Committee invite tenders for the supply of ampere-hour and watt-hour meters. Specifications and forms of tender may be obtained on application to Mr. F. E. Hughes, secretary, Electricity Department, Town Hall, Manchester, on payment of fee of £2. 2s., which amount will be refunded on receipt of a bona fide tender Tenders, addressed to the Chairman of the Electricity Committee, must be delivered at the Town Hall by Oct. 4.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Antwerp.—The Municipality of Ghent invite tenders for the construction of 10 electric cranes at that port in accordance with the specification, a copy of which may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C. An initial deposit of 2,000fr. (£80) is required to qualify

Digitized by Google

each tender, and for the tender accepted a further deposit of 18,000fr. (£720). Tenders, in registered envelopes, addressed "Au Collège Echevinal de la Ville de Gand," must be posted not later than Oct. 17. The adjudication will take place on Oct. 19.

La Rochelle (France).—The Chamber of Commerce will shortly issue tenders for a crane with a lifting power for 30 tons. The beam, or the part which projects over the water or vessel alongside, should be long enough to unload from a point about 26ft. 6in. from the edge of the quay. The height of the distal end above the quay should be 15m. (49 21ft.); the vertical distance between the edge of the quay and that part of the crane directly over it. 8m. (26 4ft.). A locomobile is preferred, but should the conditions be unfavourable for installing such a machine, then a fixed crane would be adopted.

RESULTS OF TENDERS.

Croydon.—The County Council have accepted the tender of Mason, Scott, and Co., Limited, at £519, for water purification plant in connection with the electricity works.

South Wales Collieries.—Messrs. Monté Callow and Co., 6, Ludgate-broadway, E.C., report recent orders for three 40-h.p., four 75-h.p., two 100-h.p., and three 250-h.p. "Perfecta" polyphase controllers for haulage gear.

Ballinasloe (Ireland).—The Joint Committee of the District Asylum have accepted the tender of the Edison and Swan United Electric Light Company, Limited, 12, Dawson-street, Dublin, at £258. 6s. 9d., for the supply and erection of a set of accumulators.

Power-Gas.—The Government of Bolivia have placed a contract with the Power-Gas Corporation, Limited, of 39, Victoria-street, Westminster, for one of their patent gas plants of 600 h.p. capacity. This forms part of the equipment of the generating station at La Paz, Bolivia, which is to be installed for electric tramway and lighting purposes. The equipment of the station includes also two Premier gas-engines of 400 h.p. capacity each.

Curtis Turbines for Japan.—Recently a large contract for Curtis steam-turbines for supplying power to a Japanese street railway was placed with the General Electric Company of America. Information has just come to hand that the Nagoya Electric Light Company's plant is to be extended, and for this purpose the British Thomson-Houston Company, the holders of the patent rights of the Curtis turbine for Great Britain and Ireland, inform us that a contract has been placed through the Japanese house of Mitsui and Co. for a 500-kw. Curtis turbine set.

BUSINESS NOTES.

TRACTION.

Govan.—New tramway routes are in contemplation.

Hartlepool.—The company have reconstructed about a third of the system leased from the Corporation.

Huddersfield.—The question of a medical examination of the tramway employés has again been referred back to committee.

Liverpool.—The Corporation have now decided that 100 cars shall be fitted with top covers, 10 of them to be of the permanent type.

Norwich.—The Norwich Electric Tramways Company have given notice of appeal in the action recently brought by the Corporation.

Paris General Traction Co.—This company announces the abandonment of the Diatto surface-contact system on its tramways from financial considerations.

Luton.—The plans for the tramways have been approved. A suggestion has been made that a service of motor 'buses should be introduced to act as feeders.

Calcutta Tramways.—The directors have declared an interim dividend of 3s. per share, being at the rate of 6 per cent. per annum, on account of the half-year to June 30.

Cleethorpes.—The Urban District Council are to purchase the tramway company's power station at £17,000. The company are to take energy from the Council, the price to be fixed by an independent engineer.

Rosario.—A movement is now on foot to organise a company for the purpose of building an electric railroad at Rosario, a city of about 122,000 inhabitants, in the province of Santa Fé, Argentina.—*Western Electrician.*

Maidstone.—A special meeting is to be held to consider the question of extensions. It has been decided that from Oct. 1 to April 1 the cars shall not run on Sundays between 10.30 a.m. and noon and between 6.30 and 8 p.m.

Middlesbrough.—The Corporation have decided to institute further proceedings for excessive speed on the company's tramways, and also for overcrowding. A committee is to inspect the cars, as the lifeguards are said to be unsatisfactory.

London County Council.—The Council have addressed a communication to the Camberwell Borough Council adhering to their decision not to apply for powers in the 1905 session in reference to the proposed tramway from Forest Hill to the Crystal Palace.

Belfast.—It is reported that Mr. Luke Livingstone Macassey, M.I.C.E., barrister-at-law, has been appointed by the Board of Trade to act as arbitrator in reference to the transfer of the tramway between the Belfast Street Tramways Company and the Corporation.

Tipton.—At the monthly meeting of the District Council a member enquired why the tramway company were allowed to suspend their passenger traffic on the Bloomfield route, and yet use it for the conveyance of oil-tanks, etc. A committee is to consider the matter.

Newcastle.—The line to Ponteland, leaving the existing system at Gosforth, has been completed, and is stimulating building operations along the route, which extends for some eight miles.

Croydon.—The town clerk has been instructed to include in the Corporation's Bill the following provision: "That there be an extension of the tramway system from Thornton Heath, along Grange-road and Church-road, to the borough boundary near the Crystal Palace."

Bath.—The Rural District Council and the Bath Electric Tramways Company are to enter into an agreement under which the latter will pay £20 per mile per year for the keeping in repair of the 18in. margins on either side of the metals for the whole district, commencing Sept. 29.

Cheltenham.—Everything is in readiness for a commencement of the work of extending the Cheltenham light railway to Charlton Kings and Leckhampton. The total length of rail to be laid is six miles, and it is anticipated that the cars will be running over a part, at any rate, of the extended route by Christmas.

Portsmouth.—The Corporation have decided that the surplus from the tramways for the past year of £16,028. 11s. 5d. be carried to a reserve fund. The Corporation have confirmed the negotiations for acquiring premises with a view to their demolition, in order to do away with the "S" curve referred to in these columns some time ago.

Erith.—The Tramway and Electricity Committee, who inspected the Ilford tramways a week or two ago, are to examine other systems, accompanied by the resident engineer, the idea being to study the equipment, rolling-stock, and methods of working. Wood paving is to be used for certain portions of the rack, and a widening of West-street is to be effected.

Swansea Improvements and Tramways Co.—Including £1,037 brought forward, the net profit for the half-year ended June 30, after deducting debenture interest, amounted to £5,072. It is recommended that £1,000 be transferred to reserve in reduction of the amount due to the British Electric Traction Company, and that the usual dividends be paid on the preference shares, carrying forward £2,773.

Lancaster.—The route to the Castle Station only awaits the Board of Trade inspection. It will be remembered that parliamentary powers were obtained by the Lancaster Corporation, under their 1900 Act, to construct a network of tramways in the borough at an estimated cost of £70,000. The first two sections to Scotforth and the Park were completed some time ago, and have been running several months.

Blackpool.—The receipts on the Corporation tramways for the period ending 15th inst., as compared with the corresponding period of last year, show a total increase from all sources of £4,859. 3s. 5d. No less than 771,380 more passengers were carried during the same period, and 46,680 more miles were covered. The increase on the Promenade and Lytham-road route was £3,555. 2s. 8d., on the Marton route £588. 3s. 10d., and on the New-road section £2. 17s. 1d. From annual and other tickets the increase in receipts was £702. 19s. 10d.

York.—It is stated that the company have named a price from £3,000 to £4,000 in excess of the figure (£12,000) suggested when negotiations were entered into three or four years ago, and the rolling-stock to be taken at a valuation. The company's contention is that the difference represents the amount they have since expended on the undertaking, but the Corporation are disinclined to buy at the price, and have given instructions for a valuation to be made by an independent expert, whose report they will be prepared to make the basis of negotiations.

Cardiff.—As a car was proceeding along Cathedral-road on Monday afternoon the overhead wire fell into the roadway. The conductor, having donned his rubber gloves, secured it and wound it about the standard. In a short time the officials had the broken wire tied up again with a rope, and the traffic was at no time disturbed. During the afternoon, however, the conductor had to disconnect the trolley of each car as it passed, the cars "free wheeling" over the section between the standards. The breakage was presumably caused by the wire becoming worn out by the constant "sparking."

Pontypridd.—At a meeting of the Electricity Committee a letter was read from Sir Colin Scott-Moncrieff, who has been appointed arbitrator in connection with the purchase by the Council from the British Electric Traction Company of the old horse tramway, stating that he proposed inspecting the line on Oct. 21. The date was accepted, and the clerk stated that the company were now prepared that the arbitration proceedings should be held in Pontypridd, and not in London. It was decided to advertise for a resident electrical engineer to manage the generating station and tramways, the salary to start at £300 per annum.

Rishton.—The District Council having received a notice from the solicitors to the Blackburn, Whalley, and Padiham Light Railway Company, stating that they intended to apply to the Board of Trade for an 18 months' extension of the time limited for completion of the works, it was resolved that representatives be appointed to attend any conference with the Clayton-le-Moors and Great Harwood Councils for the purpose of agreeing upon united action in regard to the above application. It transpired, however, that as the Clayton-le-Moors Council were well supplied with trams by Accrington, they had decided not to be represented at the meeting.

District Railway.—The Tower Station, which has not been used for nearly 20 years, is, states the *Railway Times*, being demolished under the scheme for the electrification of the company's system. The station was constructed about 25 years ago, and was used as a terminus before the circle was completed. When the circle was finished the station was found to be useless, and it had since been used as a wine-store. Two or three years ago the company, when seeking for certain powers, were able to get provisions made for enlarging the railway at that point. The platforms are being removed, the vacant space facilitating the work of electrification.

Digitized by Google

Swindon.—The Corporation's electric tramway system was opened last week. The 3½ miles of route have been equipped with the overhead system and seven cars have been obtained at a cost of about £38,000, and a further three miles of route have been sanctioned. At a luncheon given by the Mayor, Lord Edmond Fitzmaurice, M.P., proposed "Success to the Swindon Corporation Tramways," and expressed the opinion that the venture would be an increased source of prosperity to the town and convenience to the inhabitants. Mr. A. W. Deacon, vice-chairman of the Tramways Committee, replied.

Battersea.—On the reassembling of the Borough Council last week, the Law and Parliamentary Committee submitted a recommendation that the Council concur in the views of the Association of Metropolitan Borough Councils, which provide: "That, when a widening becomes necessary solely by reason of the construction or reconstruction of the tramways, the expense should be entirely borne by the London County Council out of the tramway account"; and that "when an improvement is urgently required irrespective of tramways, the contribution of the local authority should vary according to the importance of the improvement to the borough apart from the tramway traffic."

Glasgow.—The Tramways Committee have approved the following extensions: Paisley-road Toll to Pollokshields and Govan-hill, Pollokshields (present terminus) to Dumbreck-road, Parkhead Cross to Dalmarnock-road, Garngad-road to Blochairn-road, Wilton-street to North Kelvinside, University-avenue to Hyndland-road (Clarence-drive), Dumbarton-road to Broomhill-drive *via* Crow-road, Kirklee-road, Oran-street, Bilsland-drive, Hawthorn-street, etc., Possilpark to Lambhill, Barrachnie to Baillieston, and Tollcross to Uddingston. The proposal to extend from Spiersbridge to Barrhead was defeated. These decisions will come up for confirmation by the Corporation at their meeting on Thursday next.

Trans-Siberian Railway.—The authorities are considering a proposal to establish electric motors on the line. At present the passenger and goods traffic is so great that the number of trains in operation—now totalling 40 to 50 per day—has proved inadequate. Owing to the particularly light construction of the line and weight of rails, together with the limited water supply, it is not possible to accelerate speed, and such a heavy expenditure of time and money would be involved in relaying the lines, that it is thought preferable, notwithstanding the difficulty of obtaining a sufficient staff having the requisite technical knowledge, to introduce an electric motor service, erecting power stations at intervals of 60 to 120 miles, the energy to be distributed over the system in both directions at a tension of 100 000 volts.

Birmingham.—At the meeting of the Tramways Committee on Tuesday, a communication objecting to the Harborne tramway scheme was received from the Opposition Committee. The report stated that a canvass of the ratepayers by the committee resulted in an adverse vote of the proportion of two to one. The Tramways Committee decided that the figures should be carefully analysed and reported upon. Prior to the meeting the members paid a visit to the Miller-street depôt, where, in company with Mr. Baker, the general manager, they inspected a new pattern of cover for the top of the cars, which has been constructed from the designs of Mr. Baker, and which has already been described. The members were favourably impressed with the cover, which is to be put into service, so that its practical utility may be tested before its adoption is finally decided upon.

Swansea.—The Corporation appear to be dissatisfied with the wood blocks used by Messrs. Dick, Kerr, and Co. on a portion of the track, and also with the progress made by them, notwithstanding the assurances of Mr. Prusmann, the borough electrical engineer. Eventually the following resolutions were passed: "That the town clerk be instructed to send a letter to the contractors expressing disappointment and dissatisfaction at the manner in which the work was being carried out, and to say that unless they gave some satisfactory assurances as to the future, the Corporation would have to seriously consider the position"; and "That Messrs. Dick, Kerr, and Co. be informed that the time for the completion of the Bryn-road section expired on Sept. 1, and that the terms of the contract will be enforced." As the result of a deputation of residents from a portion of the main road and from Fabian-street, it was decided that, subject to the approval of the company, in those thoroughfares the tramway track should be paved with wood instead of granite.

Handsworth.—It is reported that the difficulty which arose between the Handsworth District Council and the South Staffordshire Tramways Company respecting the line which has been constructed between the West Bromwich boundary and the New Inns for the purpose of connecting Birmingham with the Black Country is now practically settled. A conference was held last Friday, the company being represented by Mr. J. A. Lycett (managing director) and Mr. B. Kingsford (secretary), and the District Council by Councillor E. J. Abbott (chairman), Councillor F. Tibbitts (chairman of the Tramways Committee), Mr. H. Ward (clerk), and Mr. E. Ward (assistant clerk). After a lengthy discussion, the representatives of the company expressed their willingness to compromise the question in regard to the expenditure incurred on road improvements, and eventually it was agreed to divide this outlay equally. The other points in dispute were dealt with in detail, and finally such good progress was made that all difficulties between the two bodies are understood to be practically at an end. It is hoped that the lease will be sealed to-day, and that arrangements will be made for the Board of Trade either to inspect the lines or to grant a temporary authority to run the cars forthwith. The company are anxious to run a 2½ minutes' service in connection with the cable trams.

Exeter.—The electrical engineer has reported to the Town Council as follows: "The construction of the generating plant for the tramways is well in hand, and some of it will shortly be delivered. A great deal of damage has been done to our cables by the recent excavations in all directions of the telephone and gas companies and of the water department in preparation for the tramways, in spite of constant watching by our men. Over 20 damaged spots have been discovered and made good, but a small interruption of the supply to several consumers in Paris-street on Sept. 10, and a more serious one on Sept. 16, affecting the St. Leonard's and the Alphington-street districts, have occurred from this cause. I am endeavouring to avoid further trouble by constant tests of the cables, and by providing a duplicate supply in the main streets where possible." He further reported that the erection of the tramway poles, which would shortly begin, would enable the committee to do away with some of the existing arc lamp posts, or remove them elsewhere, and rearrange and improve the present lighting and extend it if desired, and that he should be ready to put details and estimates before a joint meeting of this committee and the Lighting Committee at any time. The town clerk reported that the Lighting Committee had recommended to the Council that the joint conference should take place after the reconstruction of the committees in November.

Leicester.—The Tramways Committee reported at Tuesday's meeting of the Town Council that for the summer service next year 121 cars will be necessary for the actual service without providing any spare cars. The Council have an option till Dec. 28 of ordering 50 additional cars on the lines of those now being built, and they recommend that 20 should be ordered forthwith, making the total delivered and on order 120. The committee are of opinion that immediate steps should be taken for putting down an additional engine and generator at the power station, and that this generator should be capable of producing 1,000 kw. It is also considered necessary to provide additional boilers and to extend the car-shed, and it is further proposed to provide an oil store, and to roof in the coal-storage and coal-conveying plant when provided. The estimated cost of the proposed additional plant and cars and works is as follows: 1,000 kw. engine and electrical equipments, two boilers, etc., £22,000; roofs for coal storage shed, coal-conveying plant, and water softener, and new oil store at generating station, £1,000; additional bay to car-shed, track work at car-shed, tower wagon house, etc., £9,000; 50 additional cars and some canopy tops, £28,000. The committee request authority to apply to the Local Government Board for sanction to a loan for this amount, to proceed with the work without delay, and to do by direct labour the engine foundations and track work at the car depôt.

The Life of Tramway Wheels.—In a report presented to the Liverpool Corporation Tramways Committee, the experience with various types of wheels is brought out, the following account of which is given by a North Country journal: "The wheels of the German cars, which were the first to be used in Liverpool in 1898, were steel tyred, and those of the American cars, which followed, were chilled cast iron. The steel tyres, it was found, 'spread' in running, became loose, and were abandoned in favour of the chilled wheel, which was giving much better results on the United States cars. About 1900 the British manufacturers commenced the production of special steel-tyred wheels for street railway service, and experiments with those wheels were carefully watched. In 1902, and subsequently, a number of selected tyres were used in Liverpool. Fifty-two trams are now fitted with steel-tyred wheels, none of which has yet worn out, and therefore final figures cannot be quoted. Very divergent results have, however, been obtained. The mileage per unit of wear has varied to the extent of 50 per cent., indicating the importance of selecting tyres of suitable composition. The average life of the steel-tyred wheel is estimated at 60,000 miles, and of the chilled wheel 35,000 miles. The engineers are now engaged on the design of a new steel-tyred wheel, which, it is thought, will cost 50 per cent. less than the price at which such wheels can at present be bought in the market, and which, it is believed, will afford a life considerably in advance of the average of the former steel-tyred wheels."

Heywood.—The question of the terms upon which the Heywood tramways shall be worked was again before the Rochdale Tramways Committee last week, when the terms suggested by Heywood (described in our issue of the 16th inst.) as an alternative to those advanced by Rochdale and Bury were considered. The first set of the proposals sent in by Heywood was to the effect that Rochdale and Bury should bear the capital charges on Heywood's share of the purchase price of the company's undertaking, and the cost of reconstructing the lines and making certain street improvements. Heywood was to supply current and to have the option of taking over the undertaking at the end of 21 years on payment of £7,000. Adopting the recommendation of their sub-committee, the Rochdale committee declined to accept such terms as these, but they agreed that there was probably the basis of a settlement to be found in another set of proposals in which Heywood suggested that each authority should reconstruct and equip the lines within its own boundaries, maintain the reconstructed system in its area, and supply current for the cars. Rochdale and Bury would run cars over the Heywood lines, and the receipts be pooled and divided on some equitable plan. A meeting of the Bury Corporation was held on the same day, and the conclusion arrived at substantially agreed with that of the Rochdale Corporation. The Bury committee replied that they could not consider the first proposal, but they were prepared to discuss the second one. They would furnish the cars and the staff, and the receipts within Heywood borough would be handed to Heywood, less working expenses and a commission upon the receipts. A further conference between the three authorities subsequently took place, when the lines of Heywood's second proposal were accepted as an approximate basis for an agreement, some details being left over for further discussion. On the question of working expenses, Rochdale and Bury suggested that the payment should be 5d. per car mile run, but this and other matters of detail were left over for consideration by the committees of the respective Corporations. At a meeting of the Heywood Tramway Committee in the evening the town clerk was instructed to suggest that another meeting be held at an early date to deal further with these details.

Newcastle.—The following is a summary of the information which has been circulated (in accordance with the request of Councillor Cail) among members of the Corporation in regard to the question of depreciation and the preparation of estimates. The report of Mr. le Rossignol states that the total depreciation going on in the present electrical equipment is at the rate of £14,898 per annum. In eight years, which Mr. le Rossignol estimates is the average "life" of the greater part of the items enumerated, this will amount to £119,184, and this can be met by laying aside yearly out of revenue the sum of £12,700. and allowing it to accumulate at compound interest at 3½ per cent. The city engineer (Mr. F. Edge) estimates that renewals to the permanent way can be met by laying aside annually a sum of £12,000, and accumulating same at compound interest. These amounts apply to the present total of capital expenditure—namely, £889,779—and will require to be increased as that capital expenditure increases. The city engineer estimates that special work, junctions, and such portions of the track as receive the greatest wear will require to be renewed in eight years, at an estimated cost of £51,154; that a large proportion of the track will require renewal in 12 years, at an estimated further cost of £88,581; and that the remainder of the track will require renewal at the end of 15 years, at an estimated expenditure of £9,694. At the end of 16 years the first portion of the track will again require renewal, at an estimated cost of £51,154 At the end of 24 years the first portion will require renewal for the s cond time, and the second portion of the track, which was renewed at the end of 12 years, will again require renewal—the total estimated expenditure at this period being £139.735. The Finance Committee present the following resolution: "That the estimates for the year ending March 25, 1905, as recommended by the sub-committee on annual estimates, be confirmed; and that a renewal fund shall be created, and that last year's surplus shall form the nucleus of the said fund; and the committee hope by a thorough revision of the whole system to considerably augment the renewal fund year by year." There appears to be no provision for depreciation as required by the Corporation's Act of 1899. The city treasurer recommends that an addition be made to cover same. The estimates for the year ending March next give—car mileage, 4,600,000; total receipts, £206,400; expenses, £70,919; stores, £89,085; sundries, £18 210; and maintenance, £31,830.

Cardiff.—Mr. Arthur Ellis, Cardiff borough electrical engineer and manager, has issued his report on the working of the tramways for the year ending March last. The total income from all sources is set down at £108,442, and the working expenses at £69,478, leaving a gross profit of £39,964. The actual net surplus balance was £7,724. There was a total disposable balance of £14,976, in addition to £5,796 allocated to a loans fund suspense account, and these amounts represented the excess income over expenditure since the inception of the system. The working expenditure per car mile was equal to 5·818d. per car mile. The ratio of working expenses to receipts worked out at just under 62 per cent. The greatest burden arose in the amount required to be paid out of revenue for loan charges, which alone absorbed 3·053d. per car mile, the capital at the end of March amounting to £687 222. The receipts from fares alone total £101,794, but, says Mr. Ellis, "we are really not getting what we are entitled to receive," and "if you wish to see larger profits it can only be done by increasing or equalising the fares upon the various sections. If, on the other hand, the convenience of the public is considered the most important, then the results obtained cannot well be criticised. You cannot, however have both." The impression that the expenses were heavy was not, he considered, warranted. It is hardly fair, remarks Mr. Ellis, to make one given route return more per car mile than another by having unequal fares. "The public cannot reasonably expect the tramways to support the rates, and at the same time have the benefit of low fares," the report proceeds. "If they want the former they can only obtain the same by subscribing towards it by paying higher fares." Then he goes on, "The tramways have had to withstand a great deal of criticism both fair and unfair, but I think it a pity when some of our critics compare the net profits of the municipal undertaking's with the gross profits of the public company. Prepared on the basis of a public company the tramway accounts would show a profit last year of over £41,325, equivalent to a return of 60 per cent. on the capital, assuming the full amount to have been expended at the commencement of the year, which is not so, the capital at the time being £601.487." The passengers carried numbered 23,574,204, equivalent to 143 times the population, as against 17 718,992 in the previous year. The accident list is thus tabulated: collisions, 1,071; persons knocked down by cars, 81; falling when leaving or boarding cars, 457; miscellaneous, 82—total, 1.153. A supplementary report will be issued before the matter comes up for consideration. Mr. Ellis has been instructed to prepare a report as to the space which could conveniently be let for advertisements without disfiguring the cars, after which tenders will be invited for advertising.

LIGHTING AND GENERAL.

Belfast.—A cable is to be extended to Malone-park at a cost of £175.

Southend.—The Town Council have decided upon extensions of the electrical plant, mains, etc., at a cost of £56,000.

Kanturk.—A public meeting is to be called to consider the advisability of taking practical steps towards promoting an electric lighting scheme.

Dollar.—Messrs. Crompton and Co. are extending their electric wires in various parts of the burgh. Additional Nernst lamps are to be erected.

Crowbrough.—Subject to certain restrictions, permission has been given to the National Telephone Company, Limited, to put down underground wires.

Sunnybrow.—It having been decided to light Sunnybrow by means of electricity, a start was made with the works on Tuesday.

Swansea.—Arrangements have been made to instal both the National and Swansea municipal telephones at Skewen. It has been resolved to apply for telegraph facilities at Dynevor Post Office.

Carnarvon.—A commencement has been made by the National Electric Construction Company with the work of laying down cables in the streets for the purpose of supplying the town with electricity.

Weybridge.—The Urban District Council are asking the Board of Trade not to grant the Urban Electric Supply Company a license to supply current to Walton without giving the Council an opportunity of objecting.

Coventry.—The Corporation have received the sanction to the borrowing of £30,388 for the extension of the electricity works, and also to the borrowing of £160 for purposes connected with the supply of electrical energy.

Cleethorpes.—The Council have agreed to purchase the Cleethorpes generating station and plant for £17,000, these figures to be verified by an accountant to be appointed by the Council, the purchase to be completed on April 3, 1905.

Guildford.—The electric light failed on Sunday evening about eight o'clock, some of the churches where the services had not concluded being plunged in darkness. It is reported that the current was not restored until Tuesday evening.

Lancashire.—A conference is to be held with regard to concerted action of the various councils through whose districts the Lancashire Electric Supply Company propose to lay their electric mains. The company have offered 2½ per cent. on the takings.

Electric Meters.—We hear that the British Westinghouse Company have recently commenced an action against the Ferranti Company for infringement of their alternating-current meter patents. The case will be heard probably early in the New Year.

Wellington.—A special meeting of the Urban District Council is to be called to consider the report of Mr. R. A. Felton, M.I.C.E., and Mr. Maclean Wilson, M.D., B.Sc., on the sewage-disposal schemes, and the surveyor's report on electric lighting and refuse destructor.

Tewkesbury.—Several notices of intention to apply for a provisional order having been received, the town clerk has been instructed to take all such steps as may be necessary to obtain a provisional order enabling the Council to supply electricity within the borough.

Brush Bulletin.—The miniature edition of the Brush Electrical Engineering Company's bulletin No. 4 has just been issued, and deals with incandescent lamps, fittings, and accessories, giving at the same time views of a number of different classes of installation carried out the firm.

Basingstoke.—An enquiry has been held into the Town Council's application for sanction to borrow £16,450 for purposes of electric lighting. Various figures were placed before the inspector, including the following: population about 11,000; rateable value, £48,868; other loans outstanding, sanctioned, or in contemplation, £60,346. A petition from a number of the leading business firms who would be willing to use electric power and lighting was put in.

Luton.—The electrical engineer's last report states that since July 15 last 25,162 units had been generated, an equivalent to 937 8-c.p. lamps and five motors of 20¼ h.p. connected, making a total of 189 consumers, with 11,927 lamps and 58 motors of 199 h.p.; and that the units generated showed an increase of 48 per cent. over the corresponding period of last year. The report was received as very satisfactory. An extension of cable is to be made in the High Town-road district, at a cost of £142.

Eltham.—The Electricity Committee of the Borough Council have recommended the Council to sanction the expenditure of about £30,000 for the purpose of electric sub-stations, cables, etc., to Eltham and Lee Green. The Council at present are taking a supply of electricity for the Lee district of Eltham from Blackheath and Greenwich Company, under an agreement dated Jan. 31, 1902, and the total consumers number only 23. There are 203 electricity consumers in Woolwich and 84 in Plumstead.

Electrical Contractors' Association (Incorporated).—This association has been registered with an unlimited number of members, each liable for £1 in the event of winding-up. The objects named are to promote and protect the trade of electrical engineering in Great Britain, and to take over (so far as the same may be legally vested in this association) the property of the unincorporated association known as the National Electrical Contractors' Association. The word "Limited" is omitted from the title by license of the Board of Trade.

Stock Exchange.—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to Callender's Cable and Construction Company's further issue of £100,000 4½ per cent. first mortgage debenture stock, and to allow the following securities to be quoted in the official list: Metropolitan Railway Company's 3½ per cent. preference stock, 3½ per cent. "A" preference stock, 3½ per cent. debenture stock, and 3½ per cent. "A" debenture stock; Urban Electric Supply Company's further issue of 16,000 ordinary shares of £5 each fully paid, Nos. 34,001 to 50,000.

Constantinople.—After negotiations extending over two years, the German Telegraph Company for Eastern Europe has succeeded, Reuter says, in obtaining a concession for laying and working a cable between Custenje and Constantinople. Berlin and Constantinople will thereby be connected by a special wire, which it is proposed to extend ultimately to the Persian Gulf and the Far East. This concession interferes with the preferential rights of the Eastern Telegraph Company, which some time ago lodged a protest with the Porte, and it is now presumed that the company will demand an indemnity from the Ottoman Government.

Digitized by Google

Scarborough.—An apprentice wireman in the employ of the electric supply company met with a fatal accident at the company's transforming sub-station, St. Nicholas-street, on Tuesday. The exact cause is not known, but it is thought that deceased, while stooping, touched the main electric wire from the works with his forehead.

Kensington.—The Post Office are about to lay pipes for telephone wires, etc., in Harrow-road (south side), Gledhow-gardens (east side), Kensington Park-gardens (north side), Oxford-gardens (north side), Earl's Court-square (west side of western section), Holland-road (west side), Kensington High-street (across), Basil-street (north-west side), Church-street (east side), Abingdon-villas (north side), Essex-villas (south side). Notices from the following electric lighting companies relative to proposed extensions of their mains, etc., in the borough have been agreed to: Kensington and Knightsbridge Electric Lighting Company, Elvaston-mews; Brompton and Kensington Electricity Supply Company, Warwick-road (two) and Alma-terrace; Notting Hill Electric Lighting Company, Royal-crescent, Aubrey-walk, and Victoria-gardens.

Dartford.—According to the last accounts, there was for the year ending in March last a deficiency of £2,316, but, taking into account outstanding credit amounts, the actual loss for the year was £1,619. The net expenditure was about balanced by the net income in the ordinary revenue account, and the deficiency represents the amounts paid for interest and repayments of loans, which had in March reached a total of £34,500. Up to the last few months the inhabitants have been slow in adopting the electric light, and, as the accounts show, only £1,418 was received from private consumers, whilst the contribution for public lighting figured as £934. One hundred and ninety-two thousand units were sold out of 264,000 generated at the works, 17,000 units were used at the works, and the quantity described as "unaccounted for" is 54,000.

Hull.—Amongst the recent applications for current is one from the North-Eastern Railway Company for 222 16-c.p. lamps for the Paragon Station, and also power for working the signals. A report on the lighting of New Jameson-street and New Clarence-street, made by the chairman and engineer, was read at the last meeting of the Electric Lighting Committee. They stated that they had obtained a price of £228 for the supply and erection of the arc lamps in New Jameson-street and £83 for the supply of the Nernst lamps in New Clarence-street, and as the prices were slightly less than those for former lamps, and owing also to the fact that it was necessary to proceed with the lighting of those streets without delay, they had instructed the two firms—Messrs. Oliver and Co., Woolwich, and the Keighley Electrical Engineering Company—to proceed with the necessary work. A brief discussion followed on the question of street-lighting by electricity.

Ormskirk.—The Urban District Council have practically adopted a scheme for the electric lighting of the town at a cost not to exceed £15,000. At the last meeting of the Guardians, however, the following minutes of the Electricity and Building Committee were confirmed: "Resolved—That estimates be obtained for the sinking of a new borehole pump and electrical motor of suitable size to drive the pump. Electric lighting question: Read letter from the Ormskirk Urban District Council enclosing copy of letter from the National Electrical Construction Company offering current for lighting at 4d. per unit, and for power at 1½d. per unit, and if they gave better terms to other parties, they would reduce those terms. The electrical engineer was heard in explanation of the same, and on the terms offered by the Electrical Construction Company. It was resolved that it was desirable that the Board of Guardians should themselves undertake the electric lighting and motive power required for the workhouse, and the scheme prepared by Mr. Peers be proceeded with."

Battersea.—The cost of the public lighting by electricity of the Shaftesbury and Beaufoy Estates, which is now to be carried out, is above the previous estimate by £447, owing to the price of copper having considerably advanced since the original estimate was prepared, notwithstanding that reductions have been effected in the other items. The following particulars are available relative to applications for the supply of electrical energy to premises within the borough, including the Council buildings—viz.: quarter ended Sept. 30, lighting, number of applications, 685, June 14 638 + 47; actual, 658 (589) + 69; applied for, 50,424 8-c.p. (47,385) + 3,039; actually supplied, 46,973 8-c.p. (41,085) + 5,888; motive power* applied for, 696¾ h.p (638¼) + 58½; actually supplied, 609½ (450⅛) + 159¾. * 48 amperes for charging accumulators applied for and 28 amperes connected; 78 amperes for heating and cooking applied for and 48 amperes connected; 10 amperes for medical apparatus applied for and connected. All worn-out lamps at the libraries are to be replaced by new Ediswan lamps.

Fire.—We are informed that the fire which occurred at the Metropolitan Electric Supply Company's Tower-street sub-station, W.C., at 10.15 a.m. on Saturday last (24th inst.), arose through the short-circuiting of copper strip laid in compound, the strip leading up to the direct-current switchboard. Large quantities of gas poured off the compound owing to the heat, became ignited and destroyed the whole of the direct-current Ferranti switchboard and some E.C.C. boards, putting them entirely out of service. The copper strip bending in all directions caused short-circuits on the low-tension 'bus bars. A large part of the supply on one side of the company's network is consequently laid off, the other side fortunately standing. The fire was extinguished at 10.45 a.m. and some part of the supply was restored by that time, the whole being put in order by 12.50 (noon). With regard to the narrow escape of an employé, we learn that the smoke poured upstairs into the high-tension room (which is approached by means of an iron staircase) and was so dense that the man in charge could not get down the steps; he was compelled to make his exit through the window, and, very fortunately, was not seriously injured. Had it not been for the presence of compound but little damage would have been caused, as the station itself is practically fireproof throughout.

Hammersmith.—We understand that the Council have agreed to an application by the Society of Motor Manufacturers and Traders for a supply of electric current to Olympia in connection with a motor exhibition they intend holding there in February next. The society have concluded a contract with the proprietors of Olympia whereby the building will be altered and properly fitted up for exhibition purposes, including the wiring for lighting the premises by electricity. It is estimated that the lighting will involve the use of between 10,000 and 20,000 8-c.p. lamps, and the society are prepared to pay at the rate of 4d. per unit for the supply of electricity, and to guarantee a minimum payment of £500 at the first exhibition, which will be held from Feb. 10 to 18 next. It will be necessary to lay a special main at a cost of £1,898 to give the required supply, and in consideration of this the society will deposit with the Council £750 as security for the due payment of the current consumed and the proper care and custody of the instruments, the deposit to be retained by the Council until the installation is disconnected from the supply mains on the close of the exhibition, when any amount due to the Council would be deducted therefrom, and the balance (if any) returned. The society are also prepared to agree to take whatever electrical energy they require for extra lighting and power at their next three exhibitions at the said premises. The lighting of Shepherd's Bush Common by means of arc lamps is being proceeded with.

London Gazette.—The partnership between Joseph Marks and Hugh Clarkson, electricians and electrical engineers, at 4, Gothic-arcade, Snow-hill, Birmingham, under the style of "Marks and Clarkson," has been dissolved by mutual consent. The creditors of the Electrical Machinery Developments Company, Limited, are required, on or before Nov. 19, 1904, to send their names and addresses to Mr. F. N. Lowther, 151, Cannon-street, London, E.C., liquidator. Frederick Stone, 47, Full-street, Derby, has been released from trusteeship in the estate of Henry John Furniss, electrician, 5A, Queen-street, Derby. A first and final dividend of 4d. in the £ has been declared in the estate of the Warrington and District Electric Light and Power Company, Limited, 115, Sankey-street, Warrington. Messrs. Barnaby and Co., Limited, College-street, Rotherham, electrical engineers, have been wound up voluntarily. Mr. Henry James Allen, of St. Peter's-close, Sheffield, has been appointed liquidator. The Bath Electric Manufacturing Company, Limited, has been wound up voluntarily; Mr. Augustus C. Comley, Albion-chambers, Bristol, has been appointed liquidator. The partnership at 39 and 40, Woodcock-street, Birmingham, by William Henry Bradbury and James Marsden, under the firm of Bradbury, Marsden, and Co., electric light fittings manufacturers, has been dissolved by mutual consent. A receiving order has been made out on creditor's petition in the estate of James Marsden, electric fittings manufacturer, 40, Woodcock-street, Birmingham. A receiving order has been made out in the estate of Henry Coles, electrical engineer, 10, York-street, Swansea.

Leeds.—An enquiry has been held into an application of the City Council for sanction to borrow £100,000 for extension of electric lighting plant. The Town Clerk (Mr. R. E. Fox) stated that the electric lighting undertaking was established by the Yorkshire House-to-House Electricity Company, Limited, under the Leeds Electric Lighting Order, 1891, and was purchased by the Corporation from the company at the price of £217,420 in the year 1898. The Corporation, in July, 1901, obtained sanction to the borrowing of £505,400 for an extension of stations, etc., and in December, 1903, to a further sum of £220,000 for extensions of mains. The forward policy of the Corporation had been justified by the progress of the undertaking. In September, 1898, the number of consumers for lighting purposes was 770; in March, 1904, the number was 3,612. The number of consumers for power and heating purposes in 1898 was six; in March, 1904, it was 376. The total number of consumers in 1898 was 776; in March, 1904, it was 3,988. In 1898 the number of 35-watt lamps (or equivalent) connected to the mains, including motors, was 65,328; in March last it was 307,849. The horse-power of motors connected to the mains was 20 in 1898 and 2,963 in March this year. The capital expenditure in 1898 was £217,420; in March last it amounted to £752,509. The kilowatts of plant installed was 2,400 in 1898; in March, 1904, it was 8,740. In March, 1899, the maximum load on plant in kilowatts was 1,500; in March last it was 5,040. The units sold in the first complete year up to March, 1900, was 2,005,840; in the year ending March last it was 6,271,186. The revenue for the year ending March, 1900, was £36,221, as compared with £76,721 in the year ending March last. The expenditure on revenue account, including interest and redemption of debt, was £27,719 in the year ending March, 1900, and in the last year it was £72,290. The surplus profits in 1900 were £8,502, and last year they were £3,431. A sum of £26,361 of the proposed loan was in respect of expenditure already incurred, or on which liability was already incurred, and £72,272 was estimated in respect of further expenditure. Generally speaking, the present application was in respect to additional plant, nothing being included for mains, sub-stations, or meters.

Erith.—The report of Mr. G. E. Heath, electrical engineer, on the electricity supply undertaking for the year ending March 31, 1904 states that the plant is now in good working order throughout, and that during the latter part of the past year a great improvement had been effected in the street-lighting, which is now reliable and efficient. The Nernst lamps have been replaced by incandescent lamps for street-lighting purposes, but, the engineer says, as such a large amount of good work has been done with the Nernst lamps in other districts, it was only just to them to mention that in this district they were worked under extraordinary and adverse conditions. When some further slight alterations had been made, he had no doubt that the arc lamps would be in a perfectly satisfactory condition. The number of 8-c.p. lamps connected March 31, 1904, was 13,588, the lamp connection at the beginning of the year being 3,088, thus showing an increase of

Digitized by Google

10,500 8-c.p. lamps during the year. The aggregate horse-power of motors connected was 189 h.p., all of which had been connected during the past year. For street-lighting there were 17 arc lamps of 1,000 c.p. each, 87 half-ampere Nernst lamps, and 425 incandescent lamps of two by 8 c.p. each, making a total of 529 street lamps connected. The total mileage of cable laid in the district was 56·6 miles, made up of 11·44 miles of high-tension feeder, 8·96 miles of low-tension distributor, and 36·2 miles of street-lighting cable. The maximum load for the year was 233 kw. on Dec. 18, 1903, and the minimum load was 48 kw. on May 17, 1903. The cost per unit sold for wages amounted to no less than 1·001d., this being out of a total of all costs of 2·563d. per unit. The gross profit of £1,020. 8s. 5d. had to be set aside for interest and redemption of capital moneys, leaving a net deficit of £781. 8s. 3d. after meeting these charges, amounting to £1,801. 16s 8d. The price per unit obtained for street-lighting was only 1·511d. The total costs are 1·828d. per unit. The balance, being gross profit carried to the net revenue account, practically covered the amount of interest, and this, for a first year's working, was very gratifying, as all repairs and modifications to mains, buildings, plant, etc., had been paid for out of revenue account. If the undertaking were a private company, it would have been in a position to pay a small dividend of, say, 2¼ per cent., and place the sum of £159 to a reserve fund. The following figures are given: Total capital expended, £38,393. 5s. Number of units sold—private lighting, 216,133; street-lighting, 148,530—total, 364,663 units. Equivalent number of 8-c.p. connected, 13,588; number of public lamps—17 arc, 87 Nernst, 425 incandescent. Maximum load in kilowatts, 233. Gross revenue, £4,914. 15s. 10d.; gross expenditure, £3,894. 7s. 5d.; gross profit, £1,020. 8s. 5d.; interest and sinking fund, £1,801. 16s. 8d.; balance on year's working (deficit), £781. 8s. 3d.; gross profit, £1,020. 8s. 5d. Mr. Heath adds: "It is to me very gratifying that sufficient demand should have arisen during the year to warrant extensions to buildings and plant, and also to necessitate increasing the capacity of sub-stations. Such extensions now being carried out include one 500-kw. alternator and engine, with accessories, and two Lancashire boilers, mechanical stokers, economiser, etc., engine-room, boiler-house, and office extensions, and the provision of above-ground sub-stations at Erith and Belvedere main transforming centres. The coal bunker has already been enlarged to accommodate 250 tons of coal. Some small mains extensions are in hand, but in future I would strongly recommend that the present network be fully developed before any further outlying districts be taken in hand." The Council had previously resolved to apply for sanction to borrow £11,500 for extensions. It is now intended, in lieu of these several loans, to apply for £20,000 on account of the electricity supply undertaking, made up as follows: Capital expenditure in excess of loans sanctioned, £10,400; mains and transformers, £5,000; meters and house services, £3,600; electric fittings, motors, etc., £1,000—total, £20,000. The above-mentioned sums of £5,000 and £3,600 will probably be sufficient to cover the expenditure on mains and transformers and meters and house services for the next two years. As the alterations to the offices at the works are practically completed, the resident engineer is to obtain furniture and fittings at an approximate cost of £20. Messrs. Callender's Cable and Construction Company, Limited, requiring an additional 50 kw. of electrical power at their works, the necessary additional transformers to enable this supply to be given will be purchased at an estimated cost of £140. Subject to agreements the Council will undertake the wiring of a number of premises upon the terms of the assisted wiring scheme, we understand that in the future all cable troughing is to be made at the electricity works. The National Telephone Company, Limited, are about to lay their main cable underground; this will, in addition to diverting the poles at the new bridge, at Lower-road level crossing, clear the proposed tramways route of the company's overhead wires at several points.

PROVISIONAL PATENTS, 1904.

SEPT. 19.

20129. Improvements in mechanism for use in conjunction with apparatus for utilising electromagnetic or "Hertzian" waves. Michael Holroyd Smith, 5, St. Nicholas-road, Upper Tooting, London.

20134. Improvements in controlling apparatus for electric motors. John Klinkenberg, 121, West George-street, Glasgow. (Complete specification.)

SEPT. 20.

20200. Improvements in apparatus for controlling and operating the points of electric railways and tramways. Edward Cross, "Dunedin," Oxford-street, Rotherham, Yorks.

20219. Improvements in electricity meters. George Hookham, 4, New Bartholomew-street, Birmingham.

20233. An improved electric bracket made from a tube only. George Henry Ide, 154, Sherlock-street, Birmingham.

20277. Improved manufacture of incandescence bodies for electric glow lamps. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Akt.-Ges., Germany.) (Complete specification.)

20278. An improved electric switch. Charles Ernest Hunter and William Hodges Warren, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

20285. Improvements in fireproofing electric cables. Francis Martin, 24, Southampton-buildings, Chancery-lane, London.

20287. Improvements in or connected with the shade-holders of electric and other lamps. William James Davy, 40, Chancery-lane, London.

SEPT. 21.

20314. Improvements in and connected with electric capstans. Walter Dixon, 154, St. Vincent-street, Glasgow.

20324. A new or improved safety device for electric railways. Frank Walter Hayward and Reginald Charles Fox, 23, King-street, Norwich.

20329. Improvements in telephones. John Young, 21, Gloucester-walk, Campden-hill, Kensington, London.

20351. An improved system and apparatus for electrically operating bulkhead doors, hatches, or the like. Allen Parry Jones, 55, Chancery-lane, London. (The "Long Arm" System Company, United States.) (Complete specification.)

20363. Improvements in electric insulators. Edmund Goolding, 335, Liverpool-road, Islington, London.

20380. Improvements in electric arc lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

20381. Improvements in rectifying alternating current. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

SEPT. 22.

20413. Improvements in hangers and ears for electric conductor wires. Joseph Heap, James Bailey, Henry Heap, Abraham Richardson, Robert Billington, James Haydock, Thomas Smith Jones, and Thomas Brierley, Penny Bank-chambers, Waterhouse-street, Halifax.

20473. Improvements in electric transforming devices. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

20478. Improvements in and relating to telegraph systems. Reginald William James, 1, Queen Victoria-street, London. (Albert Cushing Crehore, United States.) (Complete specification.)

SEPT. 23.

20510. Improved electrical-pressure ironing machine. Albert Ernest Hacking and John Pycroft, 11, Burlington-chambers, New-street, Birmingham.

20523. Improvements in hangers or ears for overhead trolley wires. William Henry Allen and Levi Thomas Allen, 6, Bank-street, Manchester.

20528. A new or improved form of electrolytic meter. William Arthur Snape and Louisa Calvert, 62, Stoke Newington-road, London.

20531. Improvements in or relating to protectors for collectors, collector rings, and the like in electric machines. Alfred Julius Boult, 111, Hatton-garden, London. (Elektricitäts-Ges. Zschockelt m. b. H., Germany.) (Complete specification.)

20535. Improvements in electrical measuring and indicating instruments. Herbert Brandon White and James Pitkin, 53, Chancery-lane, London.

20536. An improved bath for therapeutic treatment by means of electric and other forms of radiant energy. William Johnson Smyth, 53, Chancery-lane, London.

20548. Improvements in automatic controllers, especially applicable for use in electric metering systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

20549. Improvements in dynamo-electric machines. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

20550. Improvements in and relating to the control of electric motors. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

20552. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

20553. Improvements in vapour electric apparatus. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

20554. Improvements in apparatus adapted for indicating or automatically controlling or varying the flow of electric current. Guy Cary Fricker, 46, Lincoln's-inn-fields, London.

20562. Improvements in light-regulating switches for incandescent electric lamps. Pedro Cardoso de Azevedo, 47, Lincoln's-inn-fields, London.

SEPT. 24.

20568. Electro-pneumatic telegraph. John Donald Macmillan, Granston Manor, Abbeyleix, Queen's County, Ireland.

20573. Improvements in or connected with starting devices for three-phase motors and other electric machines. William Henry Eccles, 16, Worfield-street, Battersea, London.

20585. Improvements in or relating to the overhead conductor system for electric traction. Arthur Augustus Brooks and George Andrew Watson, 12, Gardner-road, Liverpool.

20609. Improvements in electric meters and measuring instruments. The British Thomson Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Digitized by Google

29627. A new or improved method for the electrolytic manufacture of water-jackets, casings, and the like. Alexandre François Bosquet, 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, Feb. 10, 1904, being date of application in France.) (Complete specification.)

29630. An improved fan or exhauster for the electrification of air or other gases. Frédéric de Mare, 72, Cannon-street, London. (Date applied for under Patents Act, 1901, Sept. 24, 1903, being date of application in Belgium.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Oct. 13, 1904.

1903.

13487. Selective electrical signalling apparatus. Evans-Jackson. (American Electric Telephone Company.)

14369. Electric roasting oven. Dutertre and Nodet.

17832. Devices and apparatus for operating the tongues of points and frogs for electric and other tramways and railways. Bullough.

21240. Starting switch and automatic cut-out adapted for series-wound electric motors. Smith.

21969. Electric arc lamps. Lane and Adams.

23333. Magnetic separators for ores or like materials. Moss.

25153. Arc lamps. Cibié.

25284. Support for electric cables. Ruthven-Murray.

1904.

1128. Electric light fittings. Veritys, Limited, and Ebbutt.

2459. Compensating systems for alternating electric current generators. Creighton. (Date applied for under International Convention, Jan. 31, 1903.)

6558. Electrical signalling system for signalling on railways in case of accidents or stoppages. Wessel and Herding.

7562. Arc lamps. Nomdedeu. (Date applied for under International Convention, April 11, 1903.)

9385. Apparatus for the automatic regulation of current in electric lighting installations. Aktiengesellschaft Brown, Boveri, et Cie. (Date applied for under International Convention, April 25; 1903.)

11219. Electric switch for intermittently illuminated signs. Nusch. (Hölscher.)

11542. Apparatus for transforming a single-phase alternating electric current into single-phase or polyphase alternating electric current of lower frequency. Schulka.

12188. Method of producing electric energy by the utilisation of the chemical energy of any suitable combustible without the employment of thermal engines. Tourneur. (Date applied for under International Convention, June 11, 1903.)

12379. Adjustable support for electric light fittings. Irving.

13170. Hertzian wave projecting and receiving apparatus adapted to indicate or give warning of the presence of a metallic body such as a ship or a train in the line of projection of such waves. Hülsmeyer.

14617. Terminals for electric wires and cables. Lycett.

15472. Electric incandescent lamps. Frey.

16814. Electric installation for transmitting the time. Perret. (Date applied for under International Convention, Aug. 11, 1903.)

17167. Electric tremblers or contact breakers. Boulanger and Smith.

17285. High-tension current insulator. Kleinsteuber.

17484. Receiving system for wireless communications. Harrison. (Date applied for under International Convention, Feb. 8, 1904.)

17595. Bends, elbows, and other angle pieces for electric conduits. Conduits and Fittings, Limited, Edwards, and Brown.

17650. Electrolytic rectifier. Büttner. (Date applied for under International Convention, Aug. 13, 1903.)

18095. Telephone switchboard cords and like flexible electric conductors. Burton and Burlingham.

NOTES.

The Pacific Cable.—It is announced that arrangements are being made for the meeting of the Pacific Cable Conference, which is to take place in London in the early part of November under the chairmanship of Mr. Lyttleton. The object of the conference is to clear up certain difficulties which have arisen, and which have proved a cause of friction, especially on the question of terminal charges.

The "G.B." Surface-Contact System.—The Lincoln Corporation on Tuesday last sealed a contract for the reconstruction of their tramways upon the "G.B." surface-contact system, a description of which appeared in our issue of Jan. 8. The permanent way will be undertaken by Messrs. Wm. Griffiths and Co., Limited, while the "G.B." Surface-Contact Company will execute the electrical equipment.

The Chemical Society.—This institution has settled its programme for the ensuing session, the dates appointed for general meetings being Nov. 3 and 16, Dec. 1 and 14, Jan. 8, Feb. 2 and 15, March 2 and 15, April 6 and 19, May 4 and 17, and June 1 and 14. The time appointed for Thursday meetings is 8 p.m., and 5.30 p.m. for Wednesday meetings. Tea will be served at 5 p.m. on Wednesdays. The annual general meeting will be held on March 29.

The American Institute.—The September number of the *Transactions* of the American Institute of Electrical Engineers contains the report of the High-Tension Transmission Committee, with the discussion thereon, and the discussions on the following papers: "The Protection of High-Pressure Transmission Lines from Static Discharges," "The Use of Ground Shields in Transformers," "Conditions for Continuous Service over Lines Operated in Parallel," and "Protection of Cables from Arcs due to Failure of Adjacent Cables."

Electro-Harmonic Society.—The first smoking concert of the season is to be held in the King's Hall of the Holborn Restaurant on Friday, the 14th inst., commencing at 8 p.m. promptly. A varied programme has been organised, including vocal music by Messrs. S. Masters and F. Ranalow, and instrumental by Messrs. A. E. Izard, R.A.M., T. E. Gatehouse, and H. M. Higgs, while humorous recitations, songs, and sketches will also be provided. In addition, a marionette performance will be presented by Mr. W. Graham, through the kindness of Mr. Maskelyne. Messrs. Izard and Gatehouse are the musical directors, and the hon. secretary is Mr. W. E. Lane.

Electric Trams v. Railways.—From time to time the railway companies are reduced to sundry expedients for retaining their suburban traffic against the competition of electric tramways. Reduced rates, zone fares, accelerated services, and motorcars are among the remedies to which they have had recourse. None of these, apparently, appealed to the East and West Yorkshire Union Railway, who, in terminating their service between Leeds and the Rothwell district, frankly acknowledge the potency of the electric tramway. The Midland Company has been associated with the working of the system, but latterly the proprietors have had to contend with a loss of £200 per month. The Great Northern have also experienced the competition, and a reduction has been made in its fares. Naturally, the trams are very popular in the summer, and in this respect it is difficult for the trains to compete with them; but now that the Lancashire and Yorkshire and the North-Eastern Companies have shown the way in the electrification of their local lines, perhaps it will not be long before others follow suit.

Glasgow Section.—To celebrate the opening of the ensuing session, the Glasgow Local Section of the Institution will again hold an inaugural dinner, which will be presided over by the Lord Provost, president of the section, the date appointed being the 28th inst. It is requested that members intending to be present will apply as early as possible to the hon. secretary, Mr. E. G. Tidd, for tickets, the price of which is 7s. 6d. The first meeting will be held on the 8th prox., when an address will be delivered by the chairman, Mr. R. Robertson. As in previous years, the committee have secured the large hall in the building of the Institution of Engineers and Shipbuilders. The other dates appointed for meetings are Dec. 13, Jan. 10, Feb. 14, March 14, April 12, and May 10, the session concluding with the annual general meeting. In view of its success last year, the smoking concert will be repeated. Arrangements have made for printing advance copies of the papers, and the hope is expressed that members will co-operate by participating in the discussions and introducing visitors, so that past success may be maintained.

New Single-Phase Railway.—The *Western Electrician* of Chicago announces that the Kewanel, Cambridge, and Geneseo Railway Company are about to begin the construction of a 30-mile single-phase alternating-current railway system. The power-house, which is to be situated near Cambridge, will be of 1,000 kw. capacity in the first instance. Current will be generated at 2,200 volts and transmitted at 11,000 volts to the two end divisions of the line, where step-down transformers will be located to reduce the current back to 2,200 volts, which will be the line voltage. The central section will be supplied at 2,200 volts direct from the power-house. On the locomotive and motorcars the voltage will be reduced down to 500, at which the single-phase motors will operate. It is expected that 60 per cent. of the revenue will be derived from goods, but the company is taking steps to encourage passenger traffic. The road will be laid with 60lb. rails, the maximum gradient being 1 per cent. and the maximum curve 5deg It is of interest to note that the company expects to mine its own coal.

Compensating Windings on Direct-Current Machines.—The compensation of the armature ampere-turns and their distorting effect has been accomplished in various ways, probably the most successful being those employing the Ryan type of winding, uniformly distributed in slots in the pole-face, and connected in series with the armature. By giving the compensating winding rather an excess of ampere-turns over the armature, a commutating field of any desired amount can be ensured. Even without distributing the winding, if only a single slot is made in the centre of the pole-face, and a compensating coil wound through this slot and surrounding half the pole-face, a certain amount of compensation will result, though the armature is still free to distort the field across each half of the pole-face. If, further, the compensating coil is extended beyond the pole so as to embrace an additional commutating pole placed at the neutral point of the machine, a commutating field of any desired amount can be set up at the neutral point. M. Seidener, in the *Zeit. für Elektrotechnik*, points out that such an arrangement, besides compensating more or less for the armature ampere-turns and producing a commutating field, also tends to compound the machine, the excess of the compensating coil ampere-turns over the armature ampere-turns causing the flux through the half pole looped with the coil to increase as the current increases.

Single-Phase Motors.—In a paper, of which an abstract is given in the *Electrical World*, presented to the International Electrical Congress, Mr. Max Deri discusses

Digitized by Google

with the aid of surface and performance diagrams the various types of single-phase motors, the induced compensated series motor, and the repulsion with several modifications. The author considers that the compensated single phase with damping coil to neutralise field reactance formed by short-circuit through brushes on the commutator (Latour) represents on the whole a more completly developed repulsion motor. It possesses the disadvantage of requiring a double brush system, a special transformer is necessary, as a rule, for excitation, and it is often necessary to apply also special arrangements for regulation. The author describes his arrangement, which employs series-connected field and armature coils as in the plain series motor. Certain points on the commutator are short-circuited together, thus forming a closed-circuited armature. The machine constitutes to a certain extent an externally excited and, consequently, externally controlled induction motor. The author claims the following advantages for this motor: Brushes carrying main working currents are not used; therefore all commutator difficulties at starting and low speeds disappear entirely. The commutator can be made quite narrow, and a small number of brushes may be used. In principle, this motor is an induction motor which transmits external energy by means of transformation to a simple rotor. The motor can be started with greatest starting torque, its output can be made considerable, and its power factor made nearly unity. By this combination there is obtained an externally excited, compensated induction motor.

High-Potential, Long-Distance Transmission and Control.—At the International Electrical Congress Mr. F. G. Baum read a paper on this subject, a summary of which is given in the *Electrical World*. After giving the equations for determining the charging current for three-phase lines and the inductance pressure due to any chosen current, the author discusses the rise in pressure due to the charging current, assuming for this purpose that the actual condensance of the line is concentrated at the centre and that the leading current which it consumes is drawn through one-half of the total line inductance. In investigating the surges produced by opening a line under load or short-circuit, a similar assumption is made as to the distribution of the reactances. It is shown that, due to the series connection of the line inductance and condensance, the energy stored in the magnetic field of the conductors under condition of excess current, when the terminal circuit is opened, must pass into the line condensance and later be discharged into the inductance, the surges thus produced assuming a frequency corresponding to the square root of the product of the self-induction and capacity of the line, as is well known. The rise in potential due to the surging current is as a first approximation independent of the length of the line and equal to 200 times the interrupted current in amperes. The author describes in detail the insulator selected for the greatest transmission system in existence, that of the California Gas and Electric Corporation, which operates 700 miles of 50,000-volt transmission circuits. In the construction of the pole line, iron pins are used on all new work, and towers are considered the ideal supporters for the wires, though but few are used at present. Advantage has been taken of hills and ravines to use long spans, 1,000ft. to 1,800ft., of aluminium wires. The general practice is to generate at 2,300 volts and step up to the line voltage, the primary of the transformer being connected star with grounded neutral.

Municipal Tramways Association.—At the conference held at Liverpool last week the election of officers resulted as follows: President, Mr. Alfred Baker, Birmingham; vice-president, Mr. J. B. Hamilton, Leeds; executive committee—Messrs. Bailie Paton (Glasgow), John Aldworth (Nottingham), and Alderman Ellis (Cardiff); auditor, Mr. Dalrymple, Glasgow. Rule 3 of the association's constitution was amended so as to provide for presidents, upon retiring from that position, being members of the executive committee for three years instead of one. A recommendation of the executive committee that the matter of rail corrugation should be investigated by a special sub-committee, comprising Mr. Fell (London), Mr. Spencer (Bradford), and Mr. J. B. Hamilton (Leeds), with power to add to their number, was approved. Belfast Corporation having taken over the tramways in that city, and it being necessary to include Ireland in the association, it was decided to alter the name of the organisation from the "Municipal Association of Great Britain" to the "Municipal Tramways Association." It was decided to accept an invitation from the executive committee of the Tramways Exhibition to hold the conference in London next July. With a view to increasing the income of the association, nearly £300 per annum being required, the executive committee considered that, having regard to the great benefits that accrue to municipal undertakings in connection with the association, the municipal members might reasonably be asked to arrange for an increase of their subscriptions. It was proposed that the municipalities should increase their annual subscription from one guinea to three guineas. This proposal led to a discussion anent the inclusion as members of the association of more than one member of each municipality, and the arrangement of the association upon broader lines. In the end the recommendation to ask for the larger subscription was confirmed, on the understanding that the question of increased municipal membership of the association be taken into generous consideration by the executive committee.

Standards of Light.—This subject was dealt with by Prof. E. L. Nichols in a paper presented to the International Electrical Congress, of which an abstract appears in the *Electrical World*. The author observes that the conditions demanded of a physical standard are very far from being fulfilled in the case of the existing standards of light, and we are forced by circumstances to content ourselves for the present with finding some seasonably reliable and practical unit. The major portion of the paper is devoted to a discussion of the properties of the amyl-acetate, acetylene, and acetylene-hydrogen flames. Rough preliminary trials with apparatus for properly mixing acetylene and hydrogen in proportions which correspond to the condition of minimum sensitiveness to variations have led to the belief that with the same attention to details which has been employed in the development of the amyl-acetate lamp an excellent hydrogen-acetylene flame can be secured. The use of an incandescent solid as a primary light standard would at first sight appear to offer many advantages over any possible flame standard, but the difficulties have thus far been insuperable. The three types of light source available for such a purpose are the incandescent mantle of the Welsbach type the electric incandescent lamp, and the Nernst lamp. Since the performance of the incandescent mantle depends upon the admixture of certain oxides of the rare earths with the thorium oxide which forms the principal constituent, the satisfactory standardisation of the material would probably be found impracticable. The makers of incandescent lamps have not as yet been able to furnish a filament which will meet the conditions of reproducibility. The use of a filament of the Nernst type as a primary standard has not as yet been seriously considered. While it is probable that the future will see the development of a satisfactory primary standard based upon the electrical heating to incandescence

Digitized by Google

of carbon or of some metallic oxide, the immediate basis for standardisation of artificial light sources lies in the use of a primary standard consisting of a flame standard and the preparation of calibrated incandescent lamps as secondary standards of light.

Eighty-Thousand-Volt Transmission Line.—An experiment with an 80,000-volt transmission line, made by the Pacific Light and Power Company in connection with the Kern River system, was described by Mr. A. C. Balch at the recent meeting of the Pacific Coast Transmission Association. It appears from the account given in the *Electrical Review* of New York, that a line 16 miles in length, and consisting of three wires with an interval of 40in. between them, was under test for a couple of months, during which all sorts of weather occurred. There was an average of 80,000 volts between two of the wires and the third one. The transformers available were two of 40,000 volts each, which were connected in series, with the centre between the two grounded. Two of the wires were connected to one of the outside terminals of these transformers, and one to the other. The ammeter did not exhibit any tendency to become inoperative on account of static charge. The current to the line was approximately three amperes. This did not at any time fall more than 5 per cent The size of the wire was No. 4 B. & S. gauge. A sharp rattling sound, which appeared to be accentuated in the neighbourhood of trees and similar objects, was heard along the line at short intervals, but could never be exactly located. The sound was quite audible at a distance of 100 yards, but a reduction of 20 per cent. in the voltage caused it to practically cease. During darkness the line, and particularly the single wire, was perceived to be highly luminous, and at the tie wire on the top of the glass insulators the brilliancy was intensified. The use of the telephone line, which runs 6ft. below the other cross-arm, was found not to be impeded. The tests showed the line to operate satisfactorily as long as the insulators were new or while they were free from dust. No difference was experienced between wood and iron pins, and in no case did the current short-circuit from the wire over the insulators to the pins. The experiment has led the company to adopt a large insulator made of brown porcelain, in four pieces, and arranged so that it can easily be cleaned, and it is intended that the insulators shall be hand cleaned at least annually. Under these conditions it is believed that 66,000 volts can be used without experiencing any difficulty.

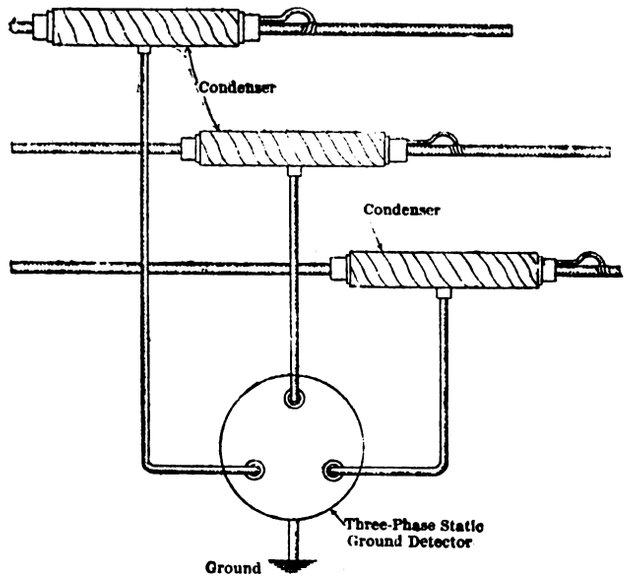
The Iron and Steel Institute.—The following particulars in connection with the American tour are supplementary to the programme described in our issue of last week. An elaborate scheme has been prepared for the tour of Pittsburg. This embraces a visit by all the members on Nov. 1 to the Westinghouse plant and to the Edgar Thomson and Homestead Steelworks, luncheon being served on the train between Edgar Thomson and Homestead. In the evening there is to be a reception at the Schenley. The second day, Nov. 2, takes in a trip to McKees Rocks to visit the plants of the Pressed Steel Car Company and the Pennsylvania Car Wheel Company, the Phœnix Glass Company at Monaca, the American Axe and Tool Company at Beaver Falls, and the great Shenango works of the American Sheet and Tin Plate Company at Newcastle. In the evening there will be a theatre party for both ladies and gentlemen. After the theatre the party will have a view of Pittsburg from the Union Club, where refreshments will be served. As an alternative, a visit will be arranged to Mount Pleasant to inspect the works and coal mines of the H. C. Frick Coke Company in the Connellsville region. Probably on the morning of the third day, Nov. 3, before leaving for Cleveland, there will be optional trips to a number of plants of all kinds in the Pittsburg district. An attractive programme has been laid out for the ladies, chiefly in form of drives. The general plan of the Reception Committee for exploring Cleveland is to take the party in a special train to Newburg on the morning of Friday, Nov. 4, visit the works of the American Steel and Wire Company, which includes the new Bessemer plant, open-hearth rolling mill and wire mill, entertain them at luncheon at the office of the works, and take the same train to the central blast furnaces of the American Steel and Wire Company, where they will see the ore-handling, furnaces, and proceed thence to the ore docks. In the evening it is proposed to entertain the members at a banquet. The ladies will be taken for a drive through the parks, and probably will lunch at the Euclid Golf Club. On Saturday morning the members will probably be split up into small parties and visit the different works. Communications intended for members during the visit may be addressed care of American Institute of Mining Engineers, 99, John-street, New York City, or care of "Aime," New York. With this programme the secretary of the institute sends us a neatly-compiled list of members participating in the tour.

The American Tour.—Having arrived at St. Louis, the members of the Institution of Electrical Engineers lost little time in repairing to the exhibition, where, on the morning of Sept. 12, the International Electrical Congress was inaugurated in the hall of the Coliseum. The numerical strength of the congress was greatly in excess of that attained by any of its predecessors, the "adhesions" approximating 2,100, of which between 400 and 500 belonged to countries outside the United States. The members actually in attendance totalled about 700. The specially-invited papers numbered over 150, of which nearly 100 were ready for distribution. It was desired by the Organisation Committee to have all of them printed in time for the opening of the congress, but there was a regrettable delay in the delivery of some of the papers. All will, however, be published in volume form and supplied to members of the congress. The congress opened with a general session, Prof. Elihu Thomson making an introductory speech, and Mr. D. R. Francis, president of the Louisiana Purchase Exhibition, delivering an address of welcome. The latter predicted that there would be fewer universal exhibitions of the Paris and St. Louis type in the future, but that there would be a greater number of exhibitions of a special character. In fact, he considered that an international electrical exhibition was likely before many years. Prof. Elihu Thomson was then elected president of the congress, with Messrs. Ascoli, Glazebrook, Gonzales, Crompton, Gray, Lombardi, Perry, and Henri Poincaré as vice-presidents. Suitable responses having been made by Messrs. Gray, Ascoli, and others, the congress resolved itself into its constituent sections and proceeded to the reading and discussion of the papers, of some of which summaries will be found in these columns. At a subsequent meeting the chamber of delegates also settled its constitution. During the week the party were entertained by the local reception committee to a number of social functions, and special attractions, including automobile rides, were provided for the ladies. Dinners were given to the delegates by Mr. B. J. Arnold, as president of the American Institute, by the congress officers, and by Mr. H. Ward Leonard, whilst Mr. George Bullock entertained the party to a luncheon. The reception held by the exhibitors was a great success, all the electrical exhibits being in operation until 10 p.m. A reception was also held at the British Pavilion, and the

Digitized by Google

week concluded with the entertainment of a large party by Mr. R. K. Gray. The visitors afterwards left for Pittsburg.

A New Three-Phase Static Ground Detector.—Single-phase ground detectors have been found to also operate satisfactorily on two-phase circuits, but for three-phase purposes, although the practice has been to use two or three single-phase instruments either in separate cases or combined in the same case, the arrangement is open to the objection that the indications of the pointer are not direct, some time being required for a person not familiar with the instruments to determine which line is grounded. The Westinghouse Electric and Manufacturing Company have now produced a three-phase static ground detector, designed for circuits of from 1,000 to 1,500 volts potential, which enables a ground in a three-phase circuit to be indicated directly by a single instrument. The accompanying diagram of connections illustrates the method of operation.



It will be seen that each of the three fixed vanes is connected to a line of the three-phase circuit. The central movable vane is electrically connected to the case, which is grounded. When there is no ground upon the circuit, the attraction or pull upon the central vane from each of the fixed vanes is balanced, and it does not deflect from a central position. Should one of the lines become grounded, and the potential of that line become the same as that of the movable vane, there will be no pull in that direction, and the movable vane will be deflected away from the grounded line. The instrument is reliable in its indications and has no complications in its mechanism or construction. In the diagram, the three leads to the ground detector are shown with a condenser inserted between each line and the instrument. This obviates the necessity of carrying high-tension wires to the front of the switchboard. Each of the condensers consists of a brass tube covered with insulating material, and placed within a copper sheath, the line being connected to the inner tube and the lead to the copper sheath.

Technical Education—The London Chamber of Commerce recently addressed the Board of Education upon the need of raising the standard and lowering the cost of higher technical education. While recognising the excellent services of existing institutions, the Chamber indicates the necessity for more efficient and economical instruction in the advanced stages of technology, especially among those designed to officer our industrial forces. In regard to elementary education, the Chamber is satisfied that recent legislation promises to provide an adequate system, and acknowledges that the Board's lately-published code of secondary education embodies many desirable features; but in order to place British manufacturers and employés upon an equality with the foremost of their competitors, it advocates the development of higher scientific education by the establishment of technical colleges of university type in connection with each group of allied industries, facilities being afforded for specialised study and the admission of capable students of limited means, and, further, the Chamber emphasises the importance of maintaining a continuous relationship between the different grades of education. The Board's response fully sympathises with the aims of the Chamber, and, without foreshadowing any decided measures, it welcomes any definite proposals for the attainment of the objects in view. The Education Act of 1902, which relieves local authorities from many restrictions and provides for a measure of co-ordination in technical education, is regarded as forming the basis of a wider and better-organised system, and the Board doubts the need of establishing at present any large number of additions to the centres of higher scientific training, to which institutions the Chancellor of the Exchequer made largely-increased grants during the late session. Some consideration is merited of the Board's opinion that British manufacturers and their employés can only attain equality with their competitors by the co-operation of the manufacturers themselves and of parents and the public generally. Reference is made to the inadequate inducement to thoroughly capable men offered in the past by many manufacturers, and to the tendency of parents to allow their sons an insufficient period in which to prepare themselves for a technical career. Without emulating some of the colossal American concerns in paying fabulous—perhaps in more senses than one—remuneration to those in charge of their undertakings, the home manufacturer might often adopt a more liberal attitude than has always obtained hitherto, while an extension in the education of those designed for such vocations could scarcely fail to be attended with beneficial results. In fact, the position which the Board of Education appears to take up is that the existing system is not by any means so bad as it is sometimes depicted; that much can be accomplished if it be fully utilised; and that if the public evince a thorough appreciation of it, the Board will be prepared to promote further facilities, so that our manufacturers and their staffs may be as well equipped in point of training as the most progressive of their rivals.

Personal.—The news that Mr. John Young had tendered his resignation of the managership of the Glasgow Corporation tramways occasioned considerable surprise, and it appears that Mr. Young was unexpectedly offered an important post by Mr. Yerkes, whose "right-hand man" he is to be in connection with the Underground Electric Railways Company of London, Limited. Entering the sanitary department of the Corporation's service in 1875, he superintended that branch with much success, and when in 1892 the Corporation decided to work the tramways Mr. Young was appointed general manager. At that time the tramways were worked by horse traction, and Mr. Young's organising capabilities were at once seen. He was one of the first to recognise the advantages of electric traction, and after one or two experimental lines had been equipped he was authorised by the Corporation to proceed with the conversion of the whole of the system owned by the municipality. This enormous work, involving an expenditure approaching two millions, was carried out against time, and Mr. Young fulfilled his promise to have the lines working electrically at the date the Glasgow Exhibition was opened in May, 1901. The capital account for the

Digitized by Google

horse tramways had to be taken over when they were electrified, but an inspection of the accounts such as we made in our leading article of Sept. 9 last shows the undertaking to be on a sound financial basis. The large annual profit, amounting to over a quarter of a million, is being used to write down the capital, so that there is no financial crisis to be feared in the future. Having done this good work at Glasgow, Mr. Young evidently feels that he can now leave the department in other hands and proceed with the still larger work of improving the congested means of traffic in the Metropolis. We have much pleasure in congratulating him upon his important appointment. Mr. Young, it will be remembered, was elected the first president of the Municipal Tramways Association. We reproduce Mr. Young's letter to the Lord Provost announcing his resignation: "Prince of Wales Hotel, Harrogate, Sept. 30, 1904. My Lord Provost,—I think it right that I should write to let you know that I have been unexpectedly offered an important post by Mr. Chas. T. Yerkes, chairman of the Underground Electric Railways Company of London, Limited, as his right-hand man in the control of the tubes and tramways of his companies. I was not looking for a new field of operation, but this proposition has come to me in such a way that I could not find any sufficient reason for declining it; so I have accepted it, and have accordingly another new start to make. By same post I am sending to the town clerk my formal resignation as from a month hence. Will you kindly accept from me my warmest thanks for your unvarying kindness and courtesy to me, and believe me, yours very sincerely (signed) John Young."

Insulation Resistance of Tramway Systems.—In his report, just presented to the convention of the International Tramways and Light Railways Association at Vienna, M. G. Pedrali, chief engineer of the Brussels tramways, deals with tests of the insulation resistance of tramway systems, an account of which is given in the *Street Railway Journal*. It is remarked that an effective and quick method of determining the existence of faults, without measurement, consists in observing the readings of the ammeter of the first dynamo during starting in the morning. If all cars are insulated from the trolley wires, and the needle of the ammeter is still deviated, it shows that the system contains a fault, which may be localised by opening the different line switches. On conduit and surface-contact systems the insulation should be regularly tested every day. "On lines both poles of which are insulated against earth," observes M. Pedrali, "it is necessary to take into account the electrolytic phenomena which tend to transport moisture from the positive to the negative pole; the greatest attention should be paid to this point." In regard to stray current, the losses per unit of pipe surface in the electricity passing between the rails and water or gas pipes may be approximately determined by the insertion of a perfectly insulated joint in the pipe, both parts of the pipe being then connected by means of a cable in which an ammeter of a resistance equal to that of the original joint is inserted. The author recommends the preparation of a diagram on which should be marked the points where the voltage difference between rails and pipes is largest, and the provision of test pipes at these points. Fig. 1 illustrates a rough way employed on some lines of testing the insulation of the trolley wire in order to find whether the insulators have a fault. A voltmeter, connected by one pole to the span wire and by the other to earth, is generally used to test the hanger, X, so as to ascertain whether the current passes over to the span wire, the strain insulator, Y, being subsequently tested by connecting the span wire between X and Y with the trolley wire and the pole to the rails, a voltmeter being inserted. This, however, gives only approximate results. The author states that the following "method of three readings" has often given good results. If A, B, C are the readings of the voltmeters as indicated in Fig. 1, R the resistance of the voltmeter, X the resistance of the hanger, and Y the resistance of the pull-off, then $X=(C-A-B)\,R/B$ and $Y=(C-A-B)\,R/A$. For ascertaining faults in conduits two groups of test lamps are provided on the switchboard,

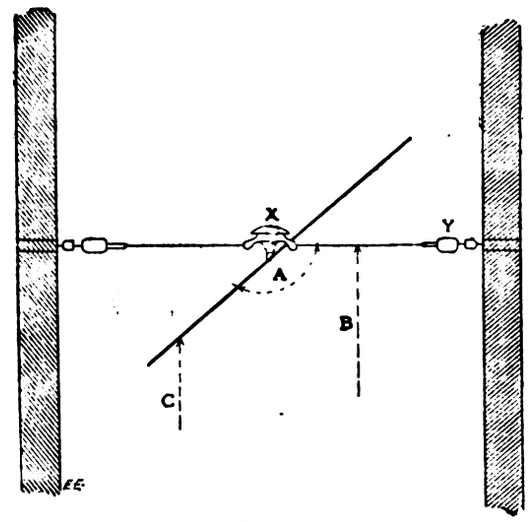


FIG. 1.

and are inserted between the two poles of the conduit, while the centre connection between the two lamp groups is connected to earth. If one of the two poles is earthed, the lamp group connected to the other pole lights up. For obviating contacts between the trolley wire and earth, caused by a foreign body, it is often sufficient to send through the line a strong current, adjustable by means of a rheostat. If it be necessary to localise the fault, the author recommends the following method of Prof. Eric Gérard: In parallel with the dynamo, a motor, M, of small

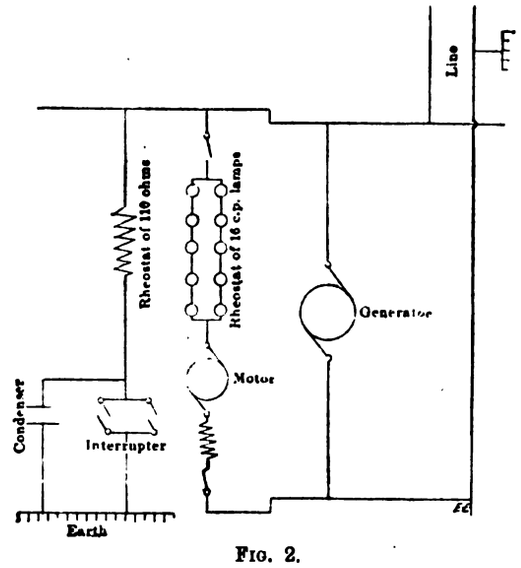

FIG. 2.

capacity is provided, which is geared to an interrupter; the other arrangements will be seen from Fig. 2. The apparatus is connected to the negative pole and the motor started. A regularly interrupted current of about five amperes now passes through the fault, the frequency of the interruptions being 70 to 80 per minute. A coil of 250 windings of ·6mm. wire, which is closed through a telephone, is then passed along the conduit. The telephone gives a regular steady noise until the fault is reached, when the noise ceases.

EXETER'S NEW ELECTRICITY WORKS.

Like its neighbour, Taunton, Exeter was one of the very first towns in the kingdom to go in for a public supply of electricity, this having been started some 15 years ago—*i.e.*, in 1899—by the Exeter Electric Lighting Company, which consisted mainly of local residents, thus evidencing the enterprise of the town. In 1896 the Corporation took over the system, which had been extended from time to time, and in 1901 still further extensions were decided upon, these involving the erection of a new generating station in a more convenient position by the River Exe.

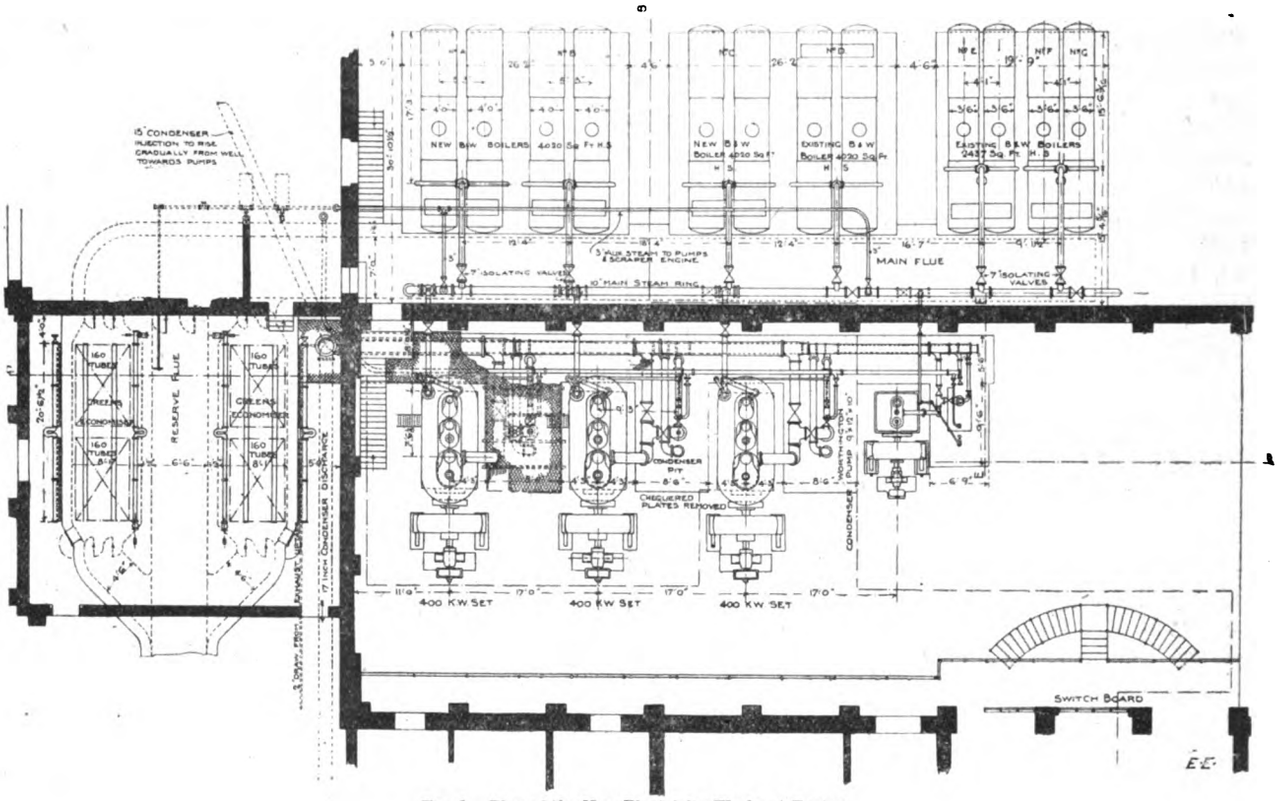

FIG. 1.—Plan of the New Electricity Works at Exeter.

The supply has hitherto been on the high-tension single-phase system, with Thomson-Houston series arc-lighting dynamos for the supply of the street lamps. The new plant is two-phase, the growing requirements for power, and the very probable early adoption of electric tramways, rendering a continuation of the old single-phase generating system impossible. Two-phase working was adopted in preference to the more orthodox three-phase, as it involved the least amount of alteration to the existing mains.

The plans and specifications for the generating station and its equipment were prepared by Mr. H. D. Munro, the city electrical engineer, who had charge of the work from its inception to the completion. It is important to note that the change from the single to the two phase system was effected without any interruption of the supply of current to consumers.

The British Westinghouse Electric and Manufacturing Company, of Trafford Park Works, Manchester, obtained the contract for the complete equipment of the new power-house, the laying of the new high-pressure mains being entrusted to Messrs. Siemens Bros. and Co. As sub-contractors to the British Westinghouse Company, Messrs. Willey and Co. were responsible for the structural iron-work, the coal conveyors (New Conveyor Company's type), coal bunkers, pipework, etc.; Messrs. Belliss and Morcom supplied the engines; Messrs. Babcock and Wilcox, the new boilers; the Worthington Pumping Engine Company, the condensers; Messrs. E. Green and Son, the economisers; and Messrs. Musker and Co, the overhead travelling crane.

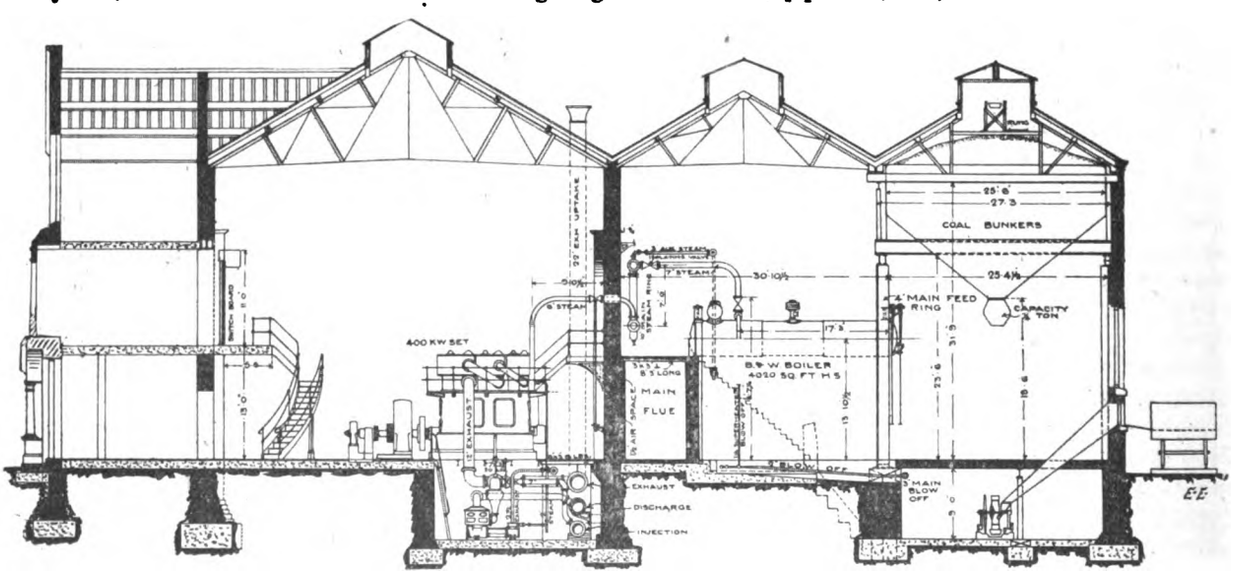

FIG. 2.—Sections of the Exeter Electricity Works.

Although the new station has been supplying current to the city mains for the past four or five months, the formal opening did not take place until the beginning of

Digitized by Google

this month, when the opening ceremony was conducted by the Mayor (Mr. F. J. Widgery), assisted by Mr. Alderman W. Wreford, J.P., and Mr. Alderman W. H. Reed, J.P., the ex-chairman and present chairman respectively of the Electric Lighting Committee. Amongst others present at the ceremony were Mr. H. D. Munro, city electrical engineer; Mr. D. Cameron, the architect; Mr. Oliver Shiras and Mr. C. A. Henderson, of the British Westinghouse Company; Henry Willey, Esq., of Messrs. Willey and Co.; Mr. D. Brealy, the builder, and various other gentlemen more or less intimately connected with the work.

The buildings at present erected cover an area of about 150ft. square, and considerable room has been allowed for future extensions. They are divided into three bays, which form the boiler-house, the engine and generator room, and the offices respectively; the economisers, boiler-feed pumps, etc., being situated in annexes. The shaft is a handsome octagonal structure of brick, and is 155ft. high, with an internal diameter of 8ft. 6in. The boiler-house is a lofty building, 102ft. long and 55ft. wide, the engine-room being of the same length, but 10ft. less in width. The floor is of terazzomosaic paving to ensure the utmost cleanliness, and galleries give access to the switchboard, as well as to the boiler-house and the various offices.

The system of handling the fuel is very complete. The coal is put into shoots which deliver it to the automatic filler of the gravity bucket coal-conveyor, which is electrically driven by a Westinghouse two-phase induction motor. This conveys the fuel to a gallery under the roof, the fuel then being dropped into one or other of the series of bunkers beneath, these bunkers having a capacity of about 13,500 cubic feet, which is equivalent to about 500 tons. The conveyor can deal with 30 tons of coal per hour. From the bunkers the coal is discharged in measured quantities into the hoppers of the chain-grate mechanical stokers. The latter are also electrically driven, and besides carrying the coal into the fires, discharge the ashes and clinker into the basement below the boilers, whence the same conveyor removes them to the ash bunker. A railway siding, at present under construction, will complete the fuel and ash handling arrangements. The boiler-house plant consists at present of three new Babcock and Wilcox boilers, each with a heating surface of 4,020 square feet, and fitted with superheaters. Eventually four of the boilers in the old station, which are of the same type, will be brought over to the new station, and the total capacity will then be 2,700 h.p. A steam-pipe ring on the boiler-house wall carries the steam into the adjacent engine-room, this being so arranged that any boiler or engine can be isolated if necessary.

The main steam-piping is 10in. in internal diameter, with branches 7in. in diameter, the steam stop valve being of the Hopkinson parallel-slide pattern. All the steam-pipes, valves, separators, drains, etc., had to pass a maker's test of 400lb. hydraulic pressure per square inch, and when erected and completed were subjected to a 200lb. per square inch test.

Fig. 1 is a plan of the boiler and generator houses, and shows also the annexe containing the economisers Fig. 2 gives a sectional elevation of the station.

The new boilers are each capable of evaporating 13,000lb. of water per hour, and they steam at a pressure of 150lb. with Welsh coal, hand firing and natural draught. They are, however, as stated above, fitted with chain-grate mechanical stokers, which are not shown on the plans. After erection the boilers were tested under a hydraulic pressure of 250lb. per square inch, and the steam and water drums, sections, and mud-drums under a pressure of 300lb. per square inch. Two of the three feed pumps are steam driven, and one electrically driven. The former are of the Worthington direct-acting type, and are each capable of delivering 2,500 gallons per hour against a boiler pressure of 150lb. The electrically-driven pump is of the Worthington three-throw plunger pattern, and has a capacity of 3,900 gallons per hour; its motor, a two-phase two-speed Westinghouse induction machine, taking 60-cycle current at either 220 or 400 volts. The two Green's economisers each consist of 320 tubes, and work at a pressure of 150lb. per square inch with cold feed water. The scrapers are of the latest pattern, the driving engine taking steam at 140lb. pressure.

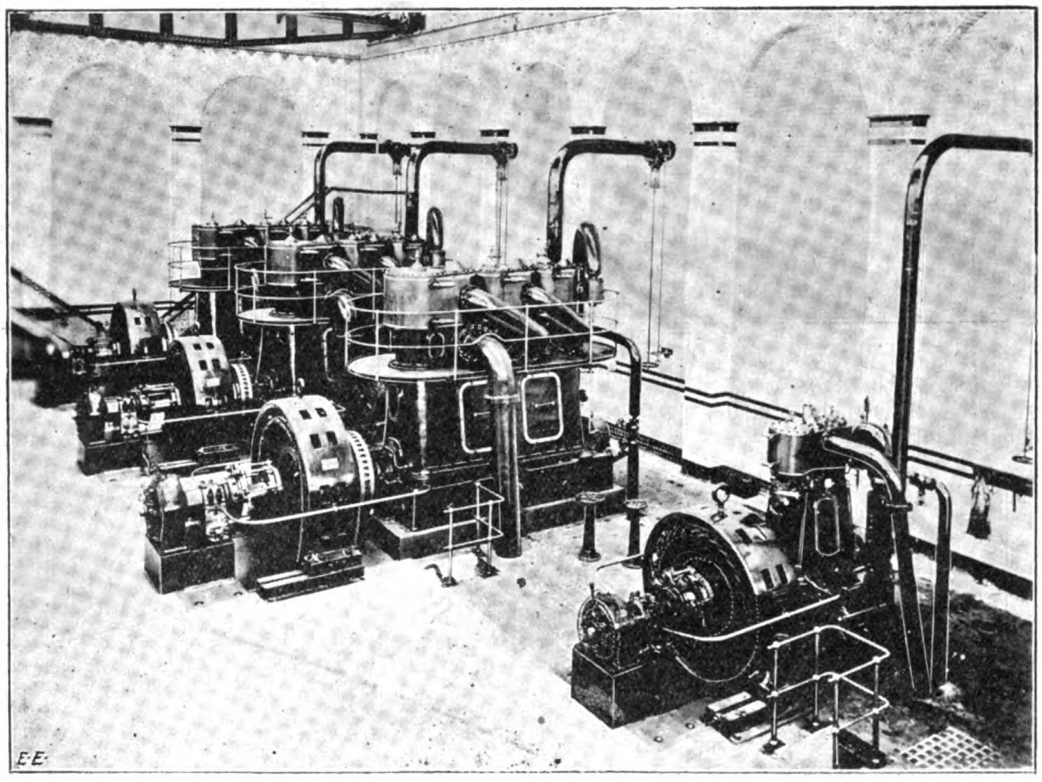

FIG. 3.—View of the Engine Room at Exeter, showing the Belliss Engines and British Westinghouse Two Phase Alternators.

The engine-room plant at present comprises four Westinghouse two-phase generators direct-coupled to Belliss and Morcom engines, three being of 400 kw. and one of 100 kw. capacity, a total of 1,300 kw. The large sets run at 360 revolutions per minute and the small one at 514 revolutions per minute, the pressure being 2,200 volts and the frequency 60. Steam is supplied at 145lb. pressure, and each engine is connected with a Worthington jet condenser. Each set is capable of dealing with one-hour overloads of 25 per cent., and the engine governors are such as to ensure that the variation of steady and momentary speed shall not exceed 5 and 10 per cent. respectively when full load is thrown on and off. The exciters are

Digitized by Google

direct-coupled, and are of the Westinghouse multipolar type. The engine-room is spanned by a 10-ton hand-power travelling crane, the span being 44ft. and the lift 18ft. This was supplied by Messrs. C. and A. Musker. Fig. 3 is a photo showing the engines and generators.

The controlling arrangements include a combined high and low tension switchboard for connecting the four generators with the six supply circuits, each generator circuit including an integrating wattmeter. The panels of the high-tension board are of marble, and provision is made for the addition of extra ones at any future time. Each alternator and feeder panel is equipped with switches, circuit breakers, ammeters, etc., of the latest Westinghouse patterns, the alternator panels being also fitted with Westinghouse synchronising gear. Three station voltmeters with switches and transformers, calibrated up to 2,200 volts, are also fitted. Arrangements are made to enable any desired generator or circuit to be isolated from the main 'bus bars and switched on to "hospital bars" for independent working. Figs. 4 and 5 give front and back views of the switchboard.

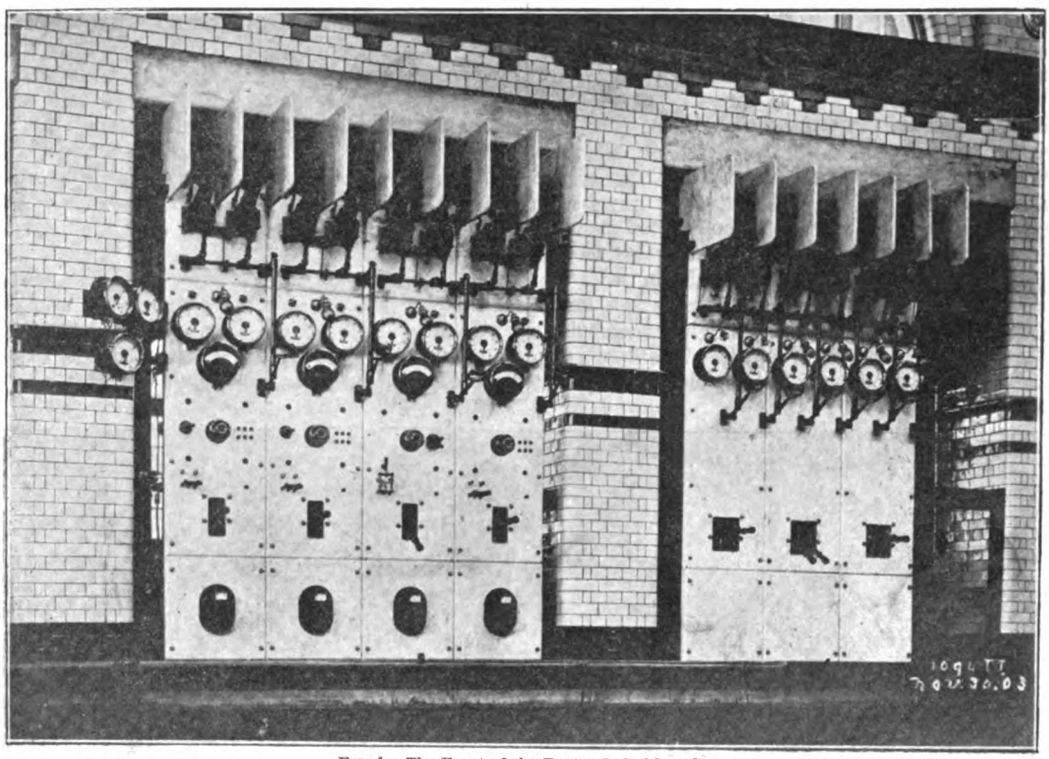

FIG. 4.—The Front of the Exeter Switchboard.

The whole of the work has been carried out on the most modern lines, the lay-out of the buildings and plant being such as to allow future extensions to be made from time to time. In this connection it may be mentioned that only one-fourth of the available ground area is at present occupied, so that the further increase of the lighting load, the development of the motor load, and the advent of the extensive adoption of electric tramways that is foreshadowed will not be difficult to cope with.

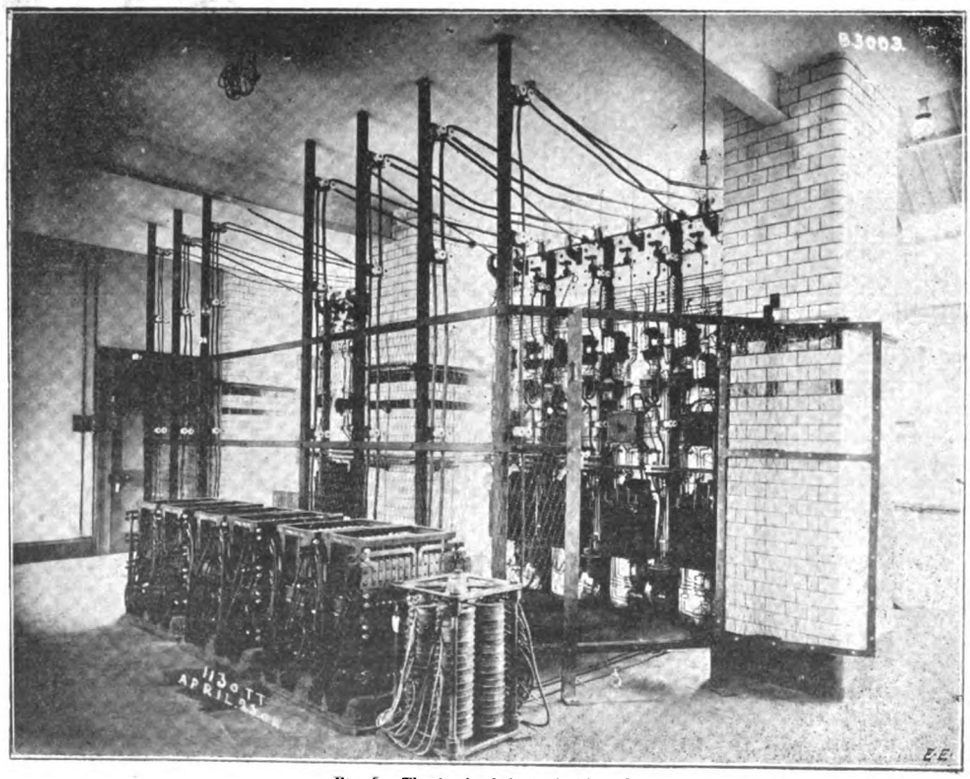

FIG. 5.—The Back of the Switchboard.

STANDARD FORM OF TRAMWAY ACCOUNTS.

The following is the accepted standard form of tramway accounts prepared by a joint committee of the Institute of Municipal Treasurers and Accountants (Incorporated) and the Municipal Tramways Association of Great Britain.

Dr. **REVENUE ACCOUNT** for year from ..... to ..... Cr.

Expenditure.	Average per car mile.	£ s. d.	£ s. d.	*Income.*	Average per car mile.	£ s. d.
To TRAFFIC EXPENSES:	d.				d.	
1. Superintendence				By TRAFFIC REVENUE		
2. Wages of motormen and conductors				By SUNDRY REVENUE:		
3. Wages of other traffic employés				Advertising on cars		
4. Cleaning and oiling cars						
5. Cleaning, salting, and sanding track						
6. Fuel, light, and water for depôts						
7. Ticket check, including wages of inspectors and clerks						
8. Uniforms and badges						
9. Miscellaneous						
To GENERAL EXPENSES:						
10. Salaries of general officers and staff						
11. Store expenses						
12. Rents						
13. Rates and taxes						
14. Printing and stationery						
15. Fuel, light, and water for offices						
16. Law charges						
17. Accident insurances and compensations						
18. Fire and other insurances						
19. Miscellaneous						
To GENERAL REPAIRS AND MAINTENANCE:						
20. Permanent way						
21. Electrical equipment of line						
22. Buildings and fixtures						
23. Workshop tools and sundry plant						
24. Cars						
25. Other rolling-stock						
26. Miscellaneous equipment						
To POWER EXPENSES*:						
27. Cost of current at ——d. per B.T.U.						
Total amount of working expenses						
Balance carried to net revenue account						
* Where there is a separate tramway power station, an abstract of the total expenses should be shown in the form provided.						

Dr. **CAPITAL ACCOUNT**, year ended ..... Cr.

Expenditure.	To March 31 190...	From April 1, 190... to March 31 190...	Total.	*Income.*	To March 31 190...	From April 1, 190... to March 31 190...	Total.

REVENUE ACCOUNT.

Classification of Working Expense Accounts.

Traffic Expenses.

Account No. 1.

Superintendence.—Charge to this account salary of traffic superintendent and assistants.

Account No. 2.

Wages of Motormen and Conductors.—Charge to this account wages of motormen and conductors engaged in operation of cars.

Account No. 3.

Wages of other Traffic Employés.—Charge to this account wages of depôt clerks, traffic regulators, trolley turners, points boys, etc.

Account No. 4.

Cleaning and Oiling Cars.—Charge to this account wages paid to car cleaners and oilers, and cost of all cleaning material, brooms, brushes, buckets, chamois skins, dusters, mops, polish, soap, sponges, waste, disinfectants, water, oil, grease, etc.

Account No. 5.

Cleaning, Salting, and Sanding Track.—Charge to this account wages of men employed in cleaning, salting, and sanding track, cost of tools for cleaning track, salt, and sand.

Account No. 6.

Fuel, Power, Light, and Water for Depôts.—Charge to this account cost of fuel for depôt offices, cost of lighting depôts, and water, other than water for cleaning cars.

Account No. 7.

Ticket Check.—Charge to this account cost of tickets, conductor's punches, wages of ticket inspectors, clerks in punch and ticket office, and deduct the receipts from advertisements on back of tickets.

Account No. 8.

Uniforms and Badges.—Charge to this account cost of uniforms and badges supplied to traffic staff.

Account No. 9.

Miscellaneous.—Charge to this account cost of Inland Revenue and police licenses for cars.

General Expenses.

Account No. 10.

Salaries of General Officers and Staff.—Charge to this account salaries of general manager, accountant, auditors, and all officers and clerks not engaged exclusively in any one department.

Account No. 11.

Store Expenses.—Charge to this account all salaries and expenses in connection with storeroom, including wages of vanmen conveying supplies from general store to depôts and collecting scrap.

Account No. 12.

Rents.—Charge to this account rental of head offices, sub-offices, and wayleaves.

Account No. 13.

Rates and Taxes.—Charge to this account all local rates and taxes, including municipal rates, police rates, poor and school rates, etc., on the annual value of the tramways undertaking.

Account No. 14.

Printing and Stationery.—Charge to this account all expenditure for printing and stationery supplies. The cost of tickets should be charged to Account No. 7.

Account No. 15.

Fuel, Light, and Water for Offices.—Charge to this account cost of coal and other fuel for head office and sub-offices, also cost of electric light, gas, and water for same.

Account No. 16.

Law Charges.—Charge to this account all legal expenses except those incurred in connection with damage claims.

Account No. 17.

Accident Insurances and Compensations.—Charge to this account the annual premium on third-party and employers' liability policies, or if claims are settled by the department the amount of claims paid and the legal expenses connected therewith.

Account No. 18.

Fire and other Insurances.—Charge to this account the annual fire, boiler, and other insurance premiums.

Account No. 19.

Miscellaneous.—Charge to this account any other sundry expenses not included in any of the foregoing accounts, including repairs to office furniture.

General Repairs and Maintenance.

Account No. 20.

Permanent Way.—Charge to this account all expenditure for repair and maintenance of track and roadway, of tracks in yards, depôts, and other buildings, including wages, material, tools, fuel, light, water, freight, cartage, and other expenses in connection with this work. The cost of preparing rails for repair of bonding, and of removing and relaying paving, etc., for repair of electrical equipment of line should be charged to Account No. 21. The expenses of the permanent-way yard, including wages of yardmen, would be distributed over the accounts benefited.

ACCOUNT No. 21.

Electrical Equipment of Line.—Charge to this account all expenditure for repair of overhead, conduit, or surface-contact electric line, including wages, material, and tools employed or used in taking up, resetting, and repainting poles, taking down trolley feed, guard, and supplementary wires and substituting new, repairing rail bonding, removing and relaying paving for repairs of the electric line, repairs to ducts and cables, section boxes, etc. The cost of repairs of electric line in yards and depôts should be charged to this account.

ACCOUNT No. 22.

Buildings and Fixtures.—Charge to this account all expenditure for repair of buildings and fixtures used in connection with the operation of the tramways, including wages, material, tools, freight, cartage of materials, and all other expenses connected with this work. The term "buildings and fixtures" includes workshops, office buildings, waiting-rooms, car sheds, stables, stores, etc., and all fixtures, including gas-pipes, water-pipes, drains, heating apparatus, lighting fittings. The cost of repair of power station and sub-station buildings should be charged to Account No. 35. The cost of repair of tracks in yards, car sheds, and other buildings should be charged to Account No. 20. The cost of repairs of electric lines in yards, car sheds, and other buildings should be charged to Account No. 21.

ACCOUNT No. 23

Workshop Tools and Sundry Plant.—Charge to this account all expenditure for repair of workshop tools, machinery, and appliances, such as engines, boilers, shafting, motors, etc. Hand tools of tradesmen should be charged to the account benefited by their use.

ACCOUNT No. 24.

Cars (including Electrical Equipment of Cars).—Charge to this account all expenditure for repair of cars, and electrical equipment of same, including wages, material, tools, freight, cartage of material, and all other expenses connected with this work. The term "cars" includes car bodies, trucks, motors, and controllers, and all fixtures or appliances inside of or attached to these parts. The cost of incandescent lamps, bell cord, trolley rope, commutator brushes, tools for motormen, etc., should be charged to this account.

ACCOUNT No. 25.

Other Rolling Stock.—Charge to this account all expenditure for repair of sundry vehicles, including water cars or carts, sand and salt cars or carts, store carts, snow ploughs, sweepers, lorries, vans, broughams, etc., including wages, material, tools, freight, cartage of material, and all other expenses connected with this work. All vehicles used exclusively for work included under any of the foregoing accounts should be charged directly to the account benefited.

ACCOUNT No. 26.

Miscellaneous Equipment.—Charge to this account all expenditure for repair of harness and cost of replacing horses, not otherwise directly charged.

Power Expenses.

ACCOUNT No. 27.

Charge to this account cost of power at a price per unit, or

*ACCOUNT No. 27.

Salaries and Wages.—Charge to this account proportion of chief engineer's salary, and all wages in the power station and sub-stations, except wages of men engaged in repairing plant. This account should include wages to the following employés: superintendent of station, engineers, greasers, feed-pump attendants, stokers, coal and ash attendants, electrical engineers, switchboard attendants, motor attendants, basement attendants, cranesmen, cleaners, boiler fitters, clerks, and storemen, watchmen, sub-station attendants, sub-station improvers, sub-station cleaners.

*ACCOUNT No. 28.

Fuel.—Charge to this account all expenditure for coal or other fuel used at the power station, including freight, cartage, and removal of ashes.

*ACCOUNT No. 29.

Water.—Charge to this account cost of water for boilers and condensers.

*ACCOUNT No. 30.

Oil and Waste.—Charge to this account all expenditure for lubrication of power plant and sub-station plant, including oil, grease, waste, rags, etc.

*ACCOUNT No. 31.

Miscellaneous Supplies.—Charge to this account all sundry expenditure in the operation of the power station and sub-stations not detailed under the foregoing accounts. Material used in repairs should not be charged to this account. The following is a list of some of the items chargeable to this account: Globe metal polish, emery and glass paper, brushes and mops, oil cans and spouts, soaps and sodas, tallow, turpentine, graphite, sternoline grease, pumice stone, ground black-lead, bathbricks, chalk, squeegees, toilet rolls, twines.

*ACCOUNT No. 32.

Repairs to Steam Plant.—Charge to this account all expenditure for wages, material, tools, freight, cartage of material, and all other expenses in connection with repair of steam plant, including engines and engine parts, appliances, and fixtures, belts, belt tighteners and fixtures, receivers, lubricators and oiling devices, boilers, furnaces, economisers, pumps, feed-water heaters, tanks, condensers, coal and ash conveyors, mechanical stokers, and other boiler-room appliances, piping and steam fitting, including valves, separators, water connections, and water-meters.

*ACCOUNT No. 33.

Repairs to Electrical Plant.—Charge to this account all expenditure for wages, material, tools, freight, cartage of material, and other expenses in connection with repair of electrical plant, including generators, switchboards, cable and feeder terminals, storage batteries, transformers, rotaries, boosters, rheostats, circuit breakers, ammeters, and other electrical equipment. Commutator brushes for generators should be charged to Account No. 31.

*ACCOUNT No. 34.

Repairs to Ducts, Cables, etc.—Charge to this account all expenditure for wages, material, tools, freight, cartage of material, and other expenses in connection with repair of ducts for cables, manholes, cables, and other electrical plant, which expense, when the power is purchased, is included in the price of the current.

*ACCOUNT No. 35.

Charge to this account all expenditure for repair of power station and sub-stations buildings, including wages, material, tools, freight, cartage of materials, and all other expenses connected with this work.

Capital Account.

CLASSIFICATION OF CAPITAL ACCOUNTS.

Permanent Way.	Cars (including electrical equipment of cars).
Electrical Equipment of Line.	Other Rolling-Stock.
Land.	Miscellaneous Equipment.
Buildings and Fixtures.	Office Furniture.
Power Station and Sub-Station Plant.*	Parliamentary Expenses.
Workshop Tools and Sundry Plant.	Preliminary Expenses.

Expenditure.

Permanent Way.—Charge to this account all expenditure for track and roadway construction, including labour, materials, tools, freight, cartage cost of grating, excavating, track laying, ties, yokes, slot rails, sewer manhole frames and covers, rails, rail fastenings, welded joints, special work (including crossings, cross-overs, curves, frogs, guard rails, switches), concrete, paving, oils, pitch, gravel, chips, asphalt, bitumen, drain boxes, sewer boxes, F.C. traps, gratings, C.I. pipes, F.C. pipes, iron paving blocks, bricks, bolts and nuts, coal, cement, dog spikes, road metal, sand, spelter, F.C. siphons, lifting wood, fences, bridges, culverts, trestles, subways, tunnels, etc., engineering and superintendence, wages of clerks, timekeepers, watchmen, light and water, street improvements, and other expenses not detailed above. The cost of tracks in car depôts and other buildings should be charged to this account. The cost of preparing rails for bonding should be charged to electrical equipment of line account.

Electrical Equipment of Line.—Charge to this account all expenditure for electrical equipment of line, including labour, materials, tools, freight, cartage, cost of preparing rails for bonding, rail bonds, *ducts, *manholes, poles, rosettes, *cables, guard wire, span wire, strain wire, supplementary wire, trolley wire, *ground feeders, *underground feeders, pole fixtures, overhead appliances, conduit appliances, surface-contact appliances, engineering and superintendence, wages of clerks and timekeepers and other expenses not detailed above.

Land.—Charge to this account cost of ground purchased for workshops, car-sheds, offices, and other buildings used in operation of line. Ground purchased to form tramway track should be charged to permanent-way account.

Buildings and Fixtures.—Charge to this account all expenditure for buildings and fixtures including labour, materials, tools, freight, cartage, and all other expenses incidental to the work. "Buildings and fixtures" includes car-sheds, *power station, *sub-stations, workshops, stores, stables, offices, waiting-rooms, etc.

**Power Station and Sub-Station Plant.*—Charge to this account all expenditure for steam and electrical equipment of power station and sub-stations, including foundations for equipment. The cost of buildings used for power station and sub-stations should be charged to buildings and fixtures account.

Workshop Tools and Sundry Plant.—Charge to this account all expenditure for shop tools and workshop machinery, car-shed tools, granary machinery, permanent-way plant, sand-drying plant, and other appliances, including foundations for same.

Cars (including Electrical Equipment of Cars).—Charge to this account all expenditure in the construction of cars from the operation of which revenue is derived. The term "car" includes the car body, truck, motors, and controllers, and all fixtures or appliances inside of or attached to these parts.

Other Rolling Stock.—Charge to this account cost of sundry vehicles, including water cars or carts, sand and salt cars or carts, store cars, snow ploughs, sweepers, lorries, vans, broughams, etc.

Miscellaneous Equipment.—Charge to this account cost of horses, harness, uniforms, cash boxes, ticket boxes, bell punches, etc.

Office Furniture.—Charge to this account cost of furniture for head office, sub-offices, etc.

Parliamentary Expenses.—Charge to this account costs of Acts of Parliament promoted by the corporation for tramway purposes.

Preliminary Expenses.—Charge to this account all preliminary organising expenses not chargeable under any of the foregoing accounts.

Income.

Credit all loans raised or repaid, also amount provided for redemption of loans, as well as any contribution by revenue to capital expenditure.

* This item only applies to systems having a separate tramway power station.

NOTES ON MOTOR-STARTING SWITCHES.

[CONTRIBUTED.]

The use of electric motors for all purposes is becoming more and more common each day. Whether the motors form part of an isolated private installation, or whether they are supplied with current from the mains of some public company, as a general rule the build and grade of the motors so installed are better than was the case some years ago. This is probably because, in the first case, the user has learnt that it is more economical in the long run to pay a decent price for the motor and so get a reliable machine built in accordance with the best modern practice, and partly because the science of electrical engineering has advanced, and not only have certain types become standardised, but the individual machines are better built, and are designed to withstand the usage they will meet with in practice, according to the particular class of work they are built for. This advance in the building of dynamos and motors is well illustrated in the building-up of the commutator. A few years ago it was quite customary to meet with plenty of machines in which, after a short period of work, the commutator segments would be found loose; now this is a fault rarely met with, as all the best makers subject the commutator to hydraulic pressure when building them up. This might be considered only a detail, but it is a most important detail, and affects the running of the machine to a very great extent, while it is only by attention to these details that a reliable machine can be turned out.

While a better class of motor is being almost universally employed, the writer regrets to note that the class of starting switch does not improve. A distinction must be clearly understood here. Better and more efficient starting switches are built to-day than was the case a few years ago, but the unfortunate part is that they are not met with in practice to any great extent; the various insurance companies who undertake the business of insuring electrical machinery against breakdown find that it is the exception to meet with installations in which the best classes of starters are used. These companies have unique opportunities for discovering what is the general trend of modern practice, for not only do they number the installations under their inspection by thousands, but they also come in contact with all classes of work carried out under expert advice and without such advice.

The fault of not putting in better starting and controlling apparatus does not lie with the motor manufacturers. Naturally they, having every confidence in their machines provided they receive anything like fair attention, would only be too pleased to put down the very best, not necessarily the most expensive, controlling apparatus possible, in order that the machines may have every opportunity of working properly. Neither does the fault lie with the makers of the starting switches; they naturally would prefer, for their own reputation, even if not for the enhanced profit, the best make of starting switch. The fault neither appears to lie with the consulting engineer, for it is only in those installations where a consulting engineer has drawn up the specification, or where the firms installing the motors have some practical knowledge of electrical motors, are these best types of starters found. The fault not lying with any of these, it would seem apparent that it rests with the contractor who instals the plant. This is right to a certain extent, for naturally if all the firms tendering only quoted for the best, then these would be installed. But the real blame lies with the purchasing firm, who too often think that all that is necessary in a motor installation is to buy some good make of motor, and then to let the work out for fixing these and running the necessary leads to some firm of contractors. Several are asked to quote, and the lowest tender is generally accepted on the simple ground it is the lowest, and without any attention being paid to the fact that each firm is tendering for valuable accessories, on which depend the successful running of the plant, and no comparison is made between the various classes of material quoted for, as though this were only a minor detail in place of being a matter of the most vital importance.

We have all heard of the Irishman who regretted that, not being a bird, he could not be in two places at the same time. Unfortunately, the manufacturer who is installing electric plant tries to successfully emulate the wish of this gentleman by looking at the question from two distinctly different standpoints at one and the same time. From one standpoint he argues that electricity is a most wonderful thing that he can't understand. He confesses he knows that a motor will develop horse-power, but why he confesses he does not know; neither does he pretend to any knowledge of the laws which govern the behaviour of a motor, nor the best conditions under which it should be run. From the other standpoint he argues it is only the putting down of a few wires and switches, which anyone can do, and that it will be better to save the expense of engaging a consulting engineer, who has made it the one object of his life to search out and discover the best arrangement of plant for any given purpose, the manufacturer forgetting all the time that upon these bits of wires and switches, etc., depend the success or failure of a plant which has cost hundreds of pounds, and on the successful working of which depends the running of his factory. The manufacturer, we have seen, has learnt to put down a good class of motor; the necessity for care in this particular has become impressed upon him, but his choice of the make of motor is often not logical. He is advised by a friend only to have those motors made by a certain firm, because this make of machine has given him every satisfaction. But he does not stop to consider why this particular make has in this instance given satisfaction. It may be that the motors are equipped with the best controlling device in the market, but the motor gets all the credit, not the starting arrangements. It may be that the motors are put down largely in excess of the power required, and in this case the opinion of a consulting engineer would have saved the amount of his fee several times over. Or, again, another manufacturer who has had a bad experience with motor driving may ultimately find that the motors which he condemned were all the time satisfactory, but that the controlling devices were not suitable, or that the motors were under their work. In either case, had a consulting engineer been engaged, the amount of his fee would have been negligible in comparison with the saving that he would have effected.

The fault, then, should be laid upon the manufacturer in many instances, and not upon the contractor. Take the case of a 30-h.p motor. It may be, having regard to the peculiar conditions of work, that the only suitable starting switch is one of the automatic self-starting type. What contractor, however, would dare to include in his tender for one of the Sturtevant switches of this class listed at £62, when an ordinary Cutler-Hammer switch can be listed at £6. 15s., knowing that one of his competitors will quote for this cheaper type, and also knowing that the tenders will be dealt with by a person having no special knowledge of the trade, and to whom it will be impossible to explain that the difference in price is a difference in value?

It is not necessary to instal in every case these high-class, expensive switches just referred to; in most cases a simpler and cheaper switch will answer all requirements, but it is necessary to see that in every case the switch is suitable for its work. There is one particular trade where a stoppage of the machinery would be the next thing to bankruptcy, and this trade is that of the printing of our great daily papers; these must be got out to time at any cost. The majority of these papers are now printed on electrically-driven presses, and a breakdown to one of these is of the rarest occurrence, although the auxiliary machinery in a printing establishment is by no means immune. The reason is not far to seek. The printing press is not supplied with a motor greatly over its work. Probably there is less margin in it than there is in the motor driving the bill machine, for instance, and the latter frequently breaks down. But—and here is the point—whatever the electric system adopted for driving the printing press, whether a Bullock-Teazer set or a Holmes-Clatworthy set, or any other similar device, is adopted, the whole is controlled by a high-class up-to-date controller, for which a high price is paid. This controller must be included, or else the firm supplying the electrical set will not complete the equipment; while in the case of the motor driving the bill

Digitized by Google

machine, any sort of a starting switch which will meet the requirements of the supply company is considered good enough.

It is worth while considering first the requirements of a good starting switch, not only as regards the requirements of the supply company, but, what is of far more importance, as regards the due protection of the machines. For a breakdown of the plant of any manufacturer stops his production, and is, therefore, almost of as much importance as the breakdown of the motor driving the printing press of a daily paper. Afterwards it will be useful to study in detail the construction of some of the higher class starters used for special purposes.

The main requirements of a good starting switch are :

1. The switch must be as simple as possible in its construction, and all parts liable to wear out should be capable of easy replacement.
2. The resistance wires used in the construction of the switch must be wound in such a manner that they cannot sag so as to touch each other, or the framework.
3. The resistance wire must be of ample area, so that no part of the resistance will heat more than 90deg. F. above the surrounding atmosphere, even if left in circuit for comparatively long periods.
4. The construction of the switch must be such that there is path afforded for the induced current of the fields when the motor is stopped.
5. The switch must be so arranged that the resistance can only be cut out slowly.
6. The switch must be so designed that in no case shall the movement of the lever from one step to the next increase the value of the current flowing through the armature by an amount sufficient to noticeably affect the E.M.F. of the supply circuit.
7. All current-bearing parts must be well insulated from the framework, and the switch must be so designed that any dampness in the atmosphere will not cause leaks to be developed.
8. All contact areas should be of ample area, and in switches designed for large currents only a small shunt current should flow between the lever and the various contact steps.
9. The switch should be fitted in every case with a suitable automatic no-volt release. An overload preventer may also be included, but this is not of the same importance.
10. All working parts should be easily accessible, and should not be placed behind the switch-slab, so as to be inaccessible without taking down the whole apparatus.
11. The mechanical design of the switch should be such that the switch will withstand the rough usage it will receive from the hands of the ordinary untrained operator.
12. The switch should be fully up to the maximum load to be dealt with by the motor.

Any starting switch built in full accordance with these requirements should suit the majority of cases. Unfortunately, few except the more expensive switches will be found to comply with the whole of the points mentioned.

The first requirement is one which should always be complied with, but many manufacturers, in order to create a fresh design, unnecessarily complicate the parts, while some other switches of simple design are spoilt by the parts subject to wear and tear being made permanent instead of replaceable. This applies particularly to the step contacts, which are liable to be burnt by the ordinary working of the switch. It is an easy matter to make these loose, and no switch should be accepted in which this requirement is not met with.

The second point is one of the greatest importance. Nothing causes so much annoyance as the stoppage of a motor owing to a defective starting switch, and it must always be remembered that in many cases the switch supplied will be operated by a man entirely ignorant of its construction or of the function of the different parts. If, then, the resistance short-circuits so that some of it is cut out, the operator will probably not notice the difference in behaviour unless the coils are actually burnt out, and he will continue to use the instrument to the detriment of the motor, although the amount of resistance of the various stages of the starting operation is not correct. If the coils do sag in use, it may be through faulty construction in the first place, but more probably through improper use, owing to the operator leaving some part of the resistance too long in circuit. Knowing that this is a likely contingency, the manufacturer should build the switch so that it is impossible for any damage to be done by so operating the switch. The simplest and safest manner of preventing this is to wind the coils on porcelain mandrils. This construction gives a sound engineering finish to the apparatus, and the switch will then stand safely large variation in temperature, and also a certain amount of rough handling. The practice which is sometimes adopted of winding the coils upon asbestos mandrils is not to be recommended. In the first place, this construction is not so rigid, and in practice the asbestos mandril is liable to give, and the sag then becomes permanent; and in the second place, this form of mandril is too often replaced by a simple fibre core, which collects hydroscopic moisture and swells, and then there is a very great fear of the coils short-circuiting.

In the Ward-Leonard type of starter the coils are enclosed in an iron box filled with sand. This is a good form, and not only does the sand act as a support to the coils to prevent short-circuit, but it also acts as an absorber of heat, and the coils will stand successfully a higher current during the operation of starting. When this device is adopted, care must be taken to see that the box is made tight-fitting, as if not, with continued use the sand may escape through any crevices. In a well-built switch, however, this fault is not likely to occur.

The third requirement is perhaps very stringent, and a higher temperature rise might be permitted, but when it is considered that the temperature of the atmosphere is often 70deg. or more, and that the whole success of the starting switch depends upon the resistance coils, it is important that due attention should be given to this point. It may be also contended that it is not intended that the current shall pass continuously through the resistance wires, but that the coils are only used as conductors for limited periods. This certainly affects the question, but, on the other hand, the apparatus is placed in the hands of unskilful persons, and in practice it is not unusual to find with certain types of starters that some part of the resistance wires is left for considerable time in circuit; again, in other cases the motor has to be constantly stopped and started, so that a good margin is not inadvisable.

The fourth requirement is one of the most important of any, while it is a well-known fact to all electrical engineers that the breaking of the shunt current in a direct-current motor induces a high induction E.M.F. Many switchmakers appear to forget that the current due to this induced E.M.F. must be provided for. A simple method of showing the existence of this high induced E.M.F. is to arrange a switch in the circuit in such a manner that just at the make and break the ends of the shunt windings are connected through incandescent lamps. In a particular case the writer saw a motor connected to a 200-volt supply fitted with such a switch; at the moment of make and break the shunt wires were connected across two 200-volt lamps in series. At the make the lamps were faintly incandescent, but at the break they momentarily glowed very brightly, so showing that owing to the self-induced E.M.F. of the shunt coils the potential difference was far in excess of 400 volts, or more than double the normal pressure. While the insulation of any motor should be arranged to safely withstand a much higher potential than that at which the machine is intended to work, yet makers cannot anticipate that it will be periodically subjected to tensions more than double of the normal. At the same time, it must be remembered that the motor is started and stopped under all conditions, at times when the windings are damp or dirty, and that at these times it will take very little to break the insulation down—a little surface moisture, or a particle of copper dust bridging across to earth, is quite sufficient.

With liquid starting switches there is yet no good device for absorbing the self-induced current, but with the more

Digitized by Google

ordinary starting switch with metallic resistance there is no difficulty when the current is not broken at the starting switch itself. All that is necessary is to connect the shunt lead to the end of the armature external resistance. If this be done as shown in Fig. 1, the movement of the starting lever to the first contact will make the circuit through the shunt fully. As the lever is moved on to the other contacts an external resistance is thrown into the shunt circuit, but the amount of drop in the pressure is not great, as the resistance is designed for the large armature current and not for the small shunt current. If the circuit be opened by another switch, the self-induced

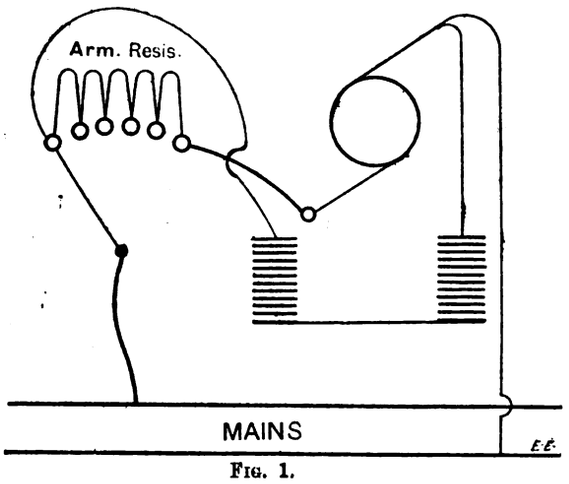

FIG. 1.

current can flow through the armature resistance and the armature itself, and so complete a closed circuit. On the other hand, if the switch is connected as shown in Fig. 2, a similar result will obtain, only in this case upon moving the switch to its first contact the circuit through the shunt is made through the armature resistance, and the shunt current is gradually increased as the armature resistance is cut out. A glance at the diagram will show that in breaking the circuit the self-induced current will at first flow through the armature and form a closed circuit, and afterwards through the armature resistance in addition.

The difference between the two methods of connection is this: With the second method of connection the induced

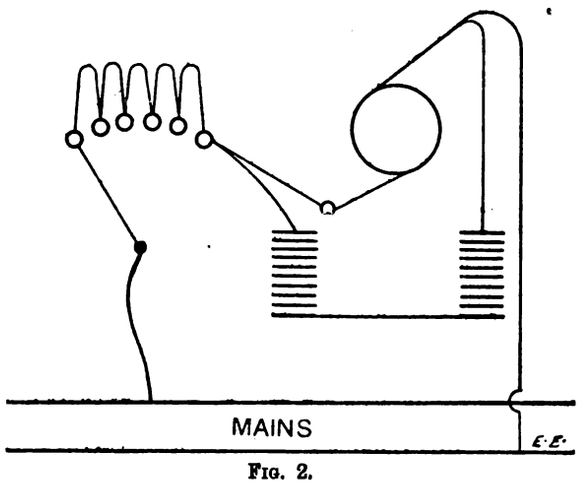

FIG. 2.

current flows through the armature only when the self-induced E.M.F. is at its highest value, and the resistance is inserted as the E.M.F. is lowering in value; this may give rise to a high value for the momentary current. With the first method of connection, however, the current flows through the greatest resistance when the E.M.F. is at its highest. The difference is not of great moment when the high resistance of the shunt windings is compared with the comparatively low resistance of the starting switch coils. If the starting switch is fitted with an automatic release, upon breaking the circuit by means of a separate switch the starting lever will come back to the off position. Now the current is broken immediately the auxiliary switch is opened, and the lever takes an appreciable time to come to the off position, and yet at times a slight spark will be noted as the lever leaves the last contact if the switch be quick acting. This spark can only be due to induction effects, and shows again the necessity for some device for absorbing the self-induced current. A consideration of the diagrams also shows the importance of inserting auxiliary switches, for with either of these methods of connecting up the switch it is impossible to arrange an absorbing path for the self-induced current of the armature if the motor be stopped by pulling the switch lever back by hand, as the shunt circuit is not then broken until the lever leaves the last contact. In this regard there are also the bad effects of the self-induced series current of a compound-wound motor to be considered, and as this is much greater than the shunt as regards value of current, disastrous sparking will occur.

(To be continued.)

THE POINTS-BOY PROBLEM, AS SOLVED BY THE ZYLBERLAST POINT SYSTEM.

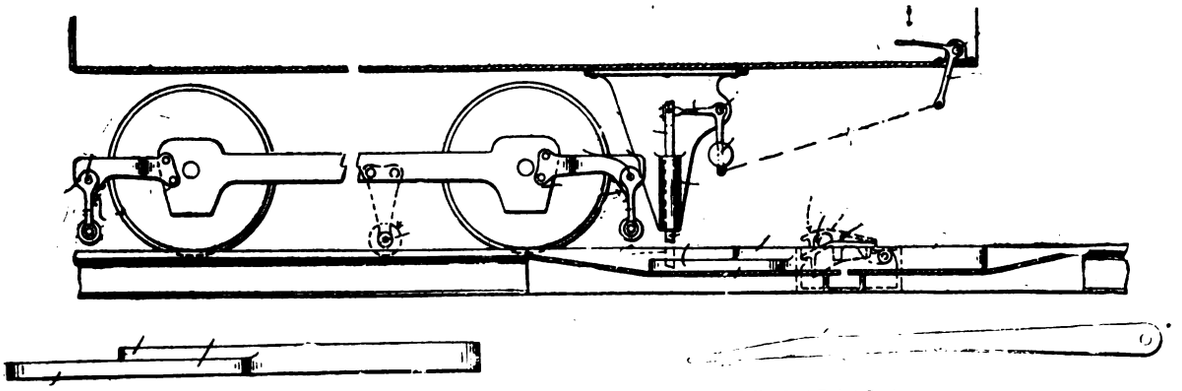
A system that can dispense with the services of those juvenile attendants who, in the intervals between long and irregular mealtimes, switch tramcars (usually) in the right direction, will deserve well of the inter-urban travelling public. Further, there is an opening for such a contrivance in places where a single line of track, with siding loops, is in vogue, as the Board of Trade enjoins either the use of an overhead switch worked by hand or a double line of wire under such conditions. The latter is more generally used, and the extra wire is, of course, of certain utility in saving power. At the same time, the need for a more mechanical arrangement in connection with both the above operations has been felt for some time, and at one or two North Country towns experiments are being made in this direction. This article deals with a system (with the somewhat ominous title of "Zylberlast") that on Saturday last was explained to a party of tramway engineers and pressmen.

A portion of the Trafford Park tramway system had been fitted with the device, likewise a tramcar, and to the casual eye the alterations to both were not noticeable. When, however, the gang of experts arrived the differences from the normal state of things were seen to be as follows: (1) On tramcar, a point-shifting plunger at each end, actuated by the driver's left heel. (2) Also, a roller at each end to replace the point in its original position. (3) On track, an enlarged groove in the rail just before the nose of point. (4) In this groove, a guide tongue attached to the nose of the point (below the wheel flange), for the point-shifting plunger to push over when required. (5) A cast-iron shoe-shaped box lid protruding slightly above the road level alongside the point. This lid is still further raised by the point being shifted, and when then struck by the roller on the back of the car, is depressed, and thus pushes the point back into its original position. These details deal with the point operations only. For keeping the overhead equipment in touch with the point, the following outrages upon the scenery awaited the hypercritical eye: (6) In roadway, marks of a recently reinstated trench dug to inter a length of gas-barrel containing a connecting wire. (7) Up the side of adjoining house, a length of gas-barrel for a continuation connecting wire. (8) On the house roof, a spiral spring and bell crank for connecting the wires at right angles. (9) Slung to span wire, more connecting wire, similar to the usual arrangement. (10) Special frog. This is pulled over to suit the direction of the track points by the connecting wire. (11) On the frog, a catch to hold the frog switch in place (when the track point is banged back by the car roller) until the trolley wheel, trailing after the car, has passed the frog. (12) Just past the frog, a curved brass arm hanging in a position to be hit by the trolley wheel. This releases the catch, so that the spring on the house eaves pulls the frog switch back to its original position.

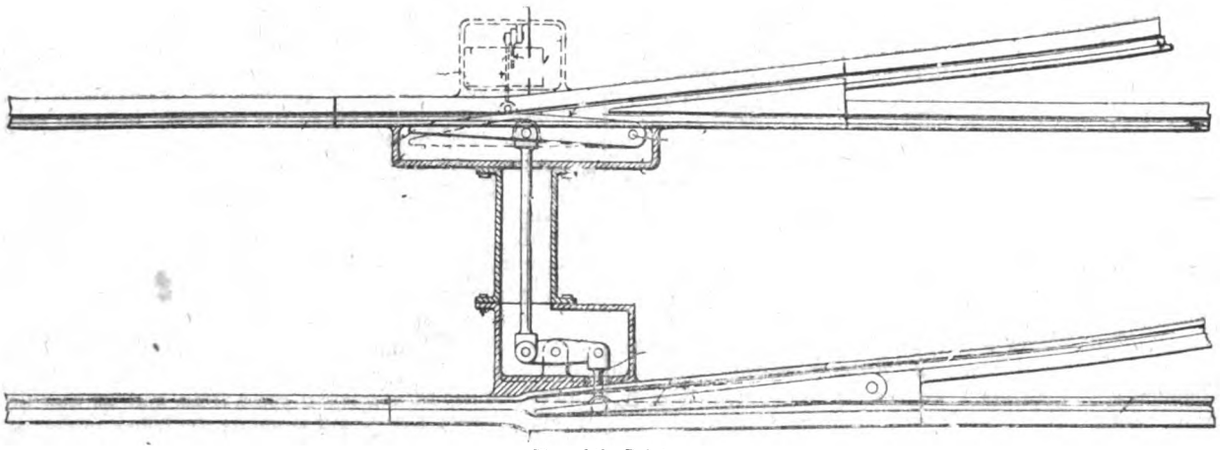
The foregoing dozen items describes the whole arrangement, save and except a box in the trap into which the action of the plunger and point sweeps the dirt that is always with us. This box has not been included in the

Digitized by Google

tabulation to prevent the unlucky numeral being saddled upon the undertaking at this period of its existence. The

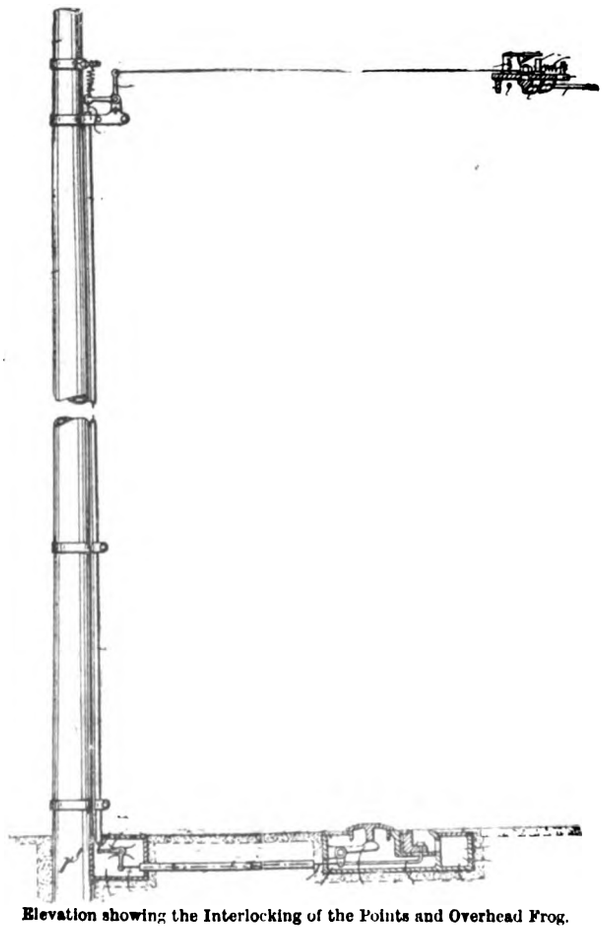


Elevation of the Underside of a Tramcar equipped on the Zylberlast Point System.



Plan of the Points.

success of the experiment was duly demonstrated by the especially fitted car being run over the points, when the



Elevation showing the Interlocking of the Points and Overhead Frog.

depression of the driver's heel and the impetus of the car did all that was necessary to guidance as required. At the present rate of electric traction invention, by the way, there will soon be an opening for persons with a surplus of limbs beyond the number given to men. On the above car, for instance, the following were operated upon by the various feet of the driver: the usual brake catch, lifeguard tripper, gong striker, and the special point plunger in question.

There are still improvements needed to overcome minor defects that are visible to the outsider, and it is understood that perfecting alterations are being made as follows: (*a*) For the shoe on box cover, that protrudes above the roadway surface, a flush slot is to be substituted, through which a trigger will emerge when the point is banged over; this trigger will be pushed back inside by the roller on the car, thus replacing the point; a spiral spring (in an oil-bath) will hold the trigger safely inside under normal conditions. (*b*) The overhead exposed springs will be replaced by counterweights. (*c*) The connecting wires in the tubes will be replaced by rods, thus avoiding chance of breakage.

When these alterations are completed, the system should be as near perfection as is possible on this sinful sphere, the only disadvantage appearing to be that the articles will not be distributed gratis. As to cost, enquirers should write to the Zylberlast Patent Point Syndicate, 20, Cross-street, Manchester: and it is understood that appointments to view the system at work can be made at short notice. A pamphlet with description, full detailed drawings, and a list of advantages running into double figures, is also to be obtained in further explanation of the system to those unable to view a demonstration.

AN EXPERIMENT TO ILLUSTRATE THE PRINCIPLE OF HORN ARRESTERS.

BY A. E. MOORE, A.M.I.E.E.

Diverging horns, attached to high-tension fuses, switches, etc., are used on some of the electric supply systems for the purpose of arresting the arc produced on opening a circuit. The arc, which is started at the lower end of the horns where they are nearest together, travels quickly upward, increasing in length until the voltage between the horns is no longer able to maintain it.

At a meeting of the Institution of Electrical Engineers,

Digitized by Google

Mr. Cowan stated that "these horn-breaks are really single-coil magnetic blow-outs; and that if the horns be inverted the arc will travel downward." Now the rising of the arc is more generally understood to be due to the influence of convection, and in some text-books convection is the only cause stated. Theoretically, as Mr. Cowan stated, both the influences of convection and electromagnetism tend to arrest the arc. In view of these statements, I recently made some experiments to determine whether the influence of convection or of electromagnetism plays the more prominent part. The result shows that convection plays only a small part. As the electromagnetic effect seems to be little known, a description of the experiments and results may be of some interest.

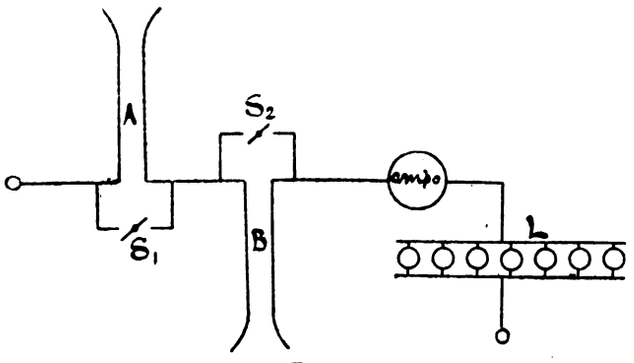


FIG. 1.

A circuit was arranged as illustrated diagrammatically in Fig. 1. A and B represent horn-breaks, and in order to intensify and prolong the effect, the horns in each break were arranged to be parallel and $\frac{3}{8}$in. apart for a length of about 10in. before diverging. They were made of No. 12 S.W.G. copper wire. S_1 and S_2 represent switches for short-circuiting the break which is not in use. L represents a bank of incandescent lamps used as a load. The circuit voltage was 110 volts, and the load when the gaps were closed 25 amperes. An arc lamp carbon was used to start the arc. S_1 was left open and S_2 closed. The circuit was then completed by bridging the gap, A, with the arc lamp carbon. On removing the carbon, the arc produced travelled up the horns and broke on the diverging part. S_2 was then opened and S_1 closed, and the experiment repeated on gap B. The result was most interesting to watch, for the arc travelled downwards and broke on the diverging part. As in the case of the gap A, the arc travelled, as it were, *away from the circuit.* The experiments were repeated a number of times with similar results. It was found, however, that the arc was rather more persistent in B than in A. This, no doubt, was due to the influence of convection.

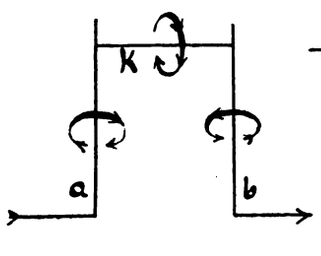

FIG. 2.

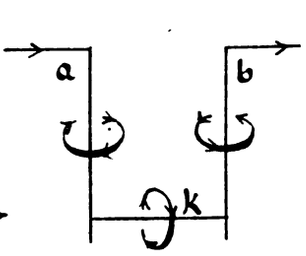

FIG. 3.

It will be well now to briefly consider the theory of this action. In Fig. 2 let *a* and *b* be the two sides of the horns, and *k* the arc. Imagine the current to be flowing from *a* to *b*, then the magnetic lines of force encircling *a*, *b*, and *k* will be as illustrated by the arrows; thus producing a mutually repelling force on the three conductors, of which the arc, *k*, is a movable one, and it therefore rises. Now, it will be seen that this repelling force only exists in virtue of the relative positions of *a*, *b*, and *k*. If *k* existed as a straight line across the exact base of *a* and *b*, no magnetic force (except it were from some external source) would be exerted upon it. Again, if we assume the horns to be removed, and the arc to exist across the ends of the conductors, no magnetic force will be exerted on it so long as it is quite straight; but if, due to any cause—convection, for instance—the arc becomes curved in any direction, then a magnetic force will be exerted on the arc, tending to burst it. This is the same effect as in Fig. 2, except that in place of the metallic horns the sides, *a* and *b*, are formed by the arc itself. It is now quite obvious that if Fig. 2 be inverted as in Fig. 3, the force on *k* will be downwards; or in any position of the horns the effect will be to force *k* to the outer and wider ends of the horns. Moreover, it is immaterial whether the current be continuous or alternating, for if the current be reversed in *a* and *b*, it is also reversed in *k*, always producing a force on *k* in the same direction—viz., towards the outer ends of the horns—no matter what their position is. This effect brings out an important point affecting the design of this form of arc-breaking device.

From the preceding lines it is obvious that if the arc is started at the points *x* and *y* (Fig. 4), it may be deflected slightly upward or downward; but if it does happen to bear ever so little downward, it will then be *forced downward.* To

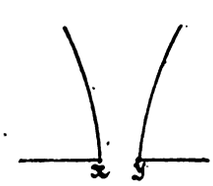

FIG. 4.

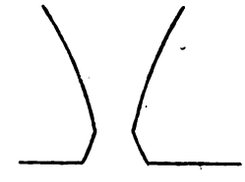

FIG. 5.

make sure that the arc shall not be deflected downwards, the fuse or switch contact must be placed a short distance up the horns; and in the case of a lightning arrester the horns should be shaped after those in Fig. 5, and not Fig. 4, so that the discharge breaking across the shortest path will be a short distance up the horns.

It was found in the experiments that when the arc was started at the very base of the horns (A, Fig. 1), that it often lingered for some seconds; sometimes fusing the horns off, sometimes breaking below, and sometimes—but by no means very frequently—it went upward. No uncertainty, however, was experienced when the arc was started above the base, the arc always travelling upward.

AYR ELECTRICITY ACCOUNTS.

The following is an abstract of the revenue account of the Ayr Corporation electricity department for the year ended May 15, 1904.

Dr. *Expenditure.*	£	s.	d.
Generation of electricity	4,069	7	2
Distribution of electricity	257	3	4
Attendance and repairs to public lamps	170	11	3
Management expenses, salaries, etc.	573	12	11
Law expenses	9	13	6
Rents, rates, taxes, etc.	357	16	8
Repairs to front property	1	15	8
Expenses of renewing mortgages	44	2	7
Special charges, insurances, etc.	215	7	7
Annual payment of expenses of opposition to Electric Power Bills	108	8	9
Balance carried to net revenue account	5,449	19	2
	£11,257	18	7

Cr. *Revenue.*	£	s.	d.
Tramway traction	1,753	17	7
Public lighting	3,590	10	8
Sale of current per meter	5,627	5	1
Miscellaneous receipts	286	5	3
	£11,257	18	7

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T.U.			1,192,629
Quantity sold	Tramways	324,157	1,047,781
	Public lamps	430,864	
	Private consumers	292,760	
Quantity used on works			63,744
Total quantity accounted for			1,111,525
Quantity not accounted for			81,164
Total maximum supply demanded (kilowatts)			529

Number of public lamps: 122 arcs and 163 incandescents.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

ELECTIVE AUDITORS.

What exactly are the duties of elective auditors we do not profess to know, and we do not pretend to care, but we do know duties which are outside their sphere of operations, and with which they ought not to be allowed to interfere. If, however, they do interfere with concerns which do not come within the purview of their work, they need a stern reminder—"hands off." South Lancashire is the home of the interfering elective auditor. Here he runs riot and desires to rule the roost. The latest phase of his activity is at Salford, in a letter by Mr. Hunt—whom we assume to be an elective auditor—to the *Salford Chronicle*. He commences with a tirade against secrecy—secrecy in selecting contracts, secrecy in prices—and then goes on to tell what everybody who pretends to know anything about municipal affairs is perfectly familiar with, that there is no such thing as secrecy. Anyone who is a ratepayer can for a small fee get to know all about contracts and prices. Mr. Hunt's whole letter is to the tune that the ratepayers elect representatives, but they ought not to trust these representatives to do anything that is not blatantly proclaimed throughout the length and breadth of the constituency. As every member of the Council knows that any elector can get the information he wants, we fail to see why he should go out of his way to proclaim it on the housetop. Mr. Hunt, as we say, knows this, for he says: "In fact, nothing which the Council has accomplished can be kept secret if knowledge is desired." Then why all this pother? It will thus be seen that Mr. Hunt himself conclusively shows his references to secrecy to be unwarranted, unless he wants committee or Council to send a copy of the agenda and minutes to every ratepayer. But secrecy is not the real trouble. The cloven hoof is seen in the following: "This is a subject well worth the attention of the miners and their friends." In other words, Mr. Hunt is playing to the gallery of trade unionism. What has it to do with an elective auditor's duties that the "strike clause in a specification is modified?" What has he to do with the clauses of a specification at all? He is not responsible for the goods purchased or the work specified in these clauses, and we should have thought that the fewer the restrictions upon a contractor the better for the purchaser. Why should not a firm object to the strike clause? They may do it on principle—not because they are better or worse masters than others, but simply because they resent interference in their own business. Our trouble is to find where an elective auditor is concerned with any clause. It seems to us that the auditor's duties begin and end with a strict examination of accounts. *Why* the committee or council decided to buy a machine from one contractor rather than another has nothing to do with the auditor. He has not had to consider the matter or compare the machines—their make or efficiency. If, however, those duties are his, neither committees nor councils are required, only elective auditors. Perhaps Mr. Hunt may not understand what is a truism to most business men who know aught of machinery—that often a thousand pounds initially saved is a loss of several thousands before the end comes. The basing of an argument for or against a council or an engineer because of a possible initial saving of a thousand pounds—one contract being that much below another—unless the things tendered for are identically alike, savours of idiotic ignorance. This is what Mr. Hunt does, and why he does it is easily seen from "In this there was no trip to Paris; in fact, it was not even necessary to leave Manchester, and they were consequently passed over." This looks like trying to curry favour with your neighbours. The chances are a million to

Digitized by Google

one but that Mr. Hunt is a "whole-hogger" in free trade, but the suggestion contained in his letter is rampant protection.

THE TRUTH.

Our contemporary the *Journal of Gas Lighting* has accepted our challenge, scored a point, and landed itself irretrievably into our hands. The point scored—and we cry peccavi—is over the grammatical construction of a sentence. Truly the sentence is involved—a comma misplaced, and a wrong ending given. Had the *Journal* been generous it would have let its

reason serve
To make the truth appear, where it seems hid
And hide the false.

The motto of *this* paper is the truth, the whole truth, and nothing but the truth; the motto of our contemporary should be special pleader. So special is it, that it hesitates not to delve in the dirtiest of literary ditches in order to serve up muck which it thinks may be used to bespatter the electrical industry. After its exhibition of this week, its influence—if it ever had any—as a special pleader is gone. Grub-street would not admit such tactics. It cannot descend lower, as we shall now prove. So eager is the writer in the *Journal of Gas Lighting* to make his point, that he proves his ignorance.

"You are too swift, Sir, to say so."

Why, before crowing over what you are pleased to term "the worse for the ratepayers," did you not look at the original figures? Fie upon you; your criticisms are trumped up second-hand. It suited your purpose to pretend to mistake, and so lead your readers to believe that Erith had an adverse balance of £1,801. You either knew better or you were ignorant of the truth. Either horn of the dilemma is good enough to spit you upon. Our contributor meant, in his involved sentence, that the deficit was £781, and *that* (£781) was the amount of the deficit after paying £1,801 capital charges. There are not two deficits, as our contemporary would make out—one £781, one £1,801—and no sensible reader would have interpreted the involved sentence to mean so, but would have sought to detect the error. Had our contemporary desired it, the rectification of the matter could have been made from p. 502 of our last issue, where the credit balance on the year's working is given as £1,020. 8s. 5d. The capital charges required £1,801. 16s. 8d., thus leaving an adverse balance deficit of £781. 8s. 3d. Our contemporary did not want the truth; it served his purpose better to assume a lie, and so make matters look as bad for Erith and the electrical industry as possible. Whether the *Journal of Gas Lighting* on p. 26 of its issue of Oct. 4 is writing ignorantly or maliciously we have no means of telling; but it can take it either way, and either is bad enough. Now a word to our contemporary. Before trying a fall with the *Electrical Engineer*, be sure of your facts, and do not prostitute the English language by crying "truth, truth," when the sole object is to hide the truth.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

BIRMINGHAM ELECTRIC CLUB.

SIR,—It has been a matter of continual surprise for some time past that in Birmingham and the surrounding district those who are engaged in electrical work know so little of each other. In the different branches of the work this is very marked, and it is so in a great measure with those engaged in the same branch. Consequently it has been thought that a club would be instrumental in rectifying this, and from enquiries made it is found that the suggestion of a club is heartily received by individuals in railway telegraphs, postal telegraphs, National Telephone Company, electric light, technical schools, manufacturers, construction, traction, and professional. Two circulars have been issued (copies herewith), and the first meeting is to take place on Saturday next at the Colonnade Hotel, one of the chief hotels in the city. The first meeting will, of necessity, be mainly devoted to the business of outlining the club, appointing a committee, etc.

From enquiries I learn there is at present no such club in existence. The Westinghouse Company in America have, as you are probably aware, an "Electric Club" in their works, supported by the firm, and they have a periodical, entitled "The Electric Club Magazine." Also, at their branch works, in Manchester, England, they have a similar club, but in each case it partakes more of a technical school than a club.

The club we are about to form here will be called an "Electric Club." My fellow-workers join me in asking that you will kindly mention in your next issue the effort we are making to form this "Electric Club," and if you are favourable to so doing, you may, if you think well, produce a copy of the first circular, herewith enclosed. We think that if you will do this, it will greatly assist us.—Yours, etc.,

W. DALBY.

Birmingham, Oct. 4, 1904.

The circular, which is written from Mr. W. Dalby's address at 187, Ombersley-road, Sparkbrook, reads as follows:

"Proposed Electric Club.—Dear Sir,—A meeting will be held *re* the above on Saturday night next, Oct. 8, at the Colonnade Hotel, time 7 p.m., when we trust to have the pleasure of your presence to assist in the formation of such a desirable institution.—We beg to remain, faithfully yours, W. Dalby, M. G. Waggott, W. H. Whitehouse, M.I.E.E."

[N.B.—If this proposed club is well managed by a committee representing all branches of electrical work, it should do a great deal of good. We would suggest that the local section of the Institution of Electrical Engineers should take the matter up, and that club dinners before each meeting of the section should be held.—ED. *E. E.*]

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

X.—ON DRUDGERY.

MY DEAR YOUNG 'UN,—If it is of any interest to you to know it, you have given me the hump. Your letter is a fearful whine from one end to the other. You can't see how you are going to learn anything under your present foreman. Your mates tell you a thing is so because it *is* so, and don't know any other reason. You have been stuck on a drilling machine for six months, and, for all you can see, are likely to stick for another six. In other words, you have been injudicious enough to turn up your nose at your work, and mad enough to write to me stating the same.

Now, in the first place, how long have you been in the shops—ten minutes or a quarter of an hour? Not so long ago you were all on fire to start work. Now you are as damp and chilly as a mudbank in winter. If six months' work is going to do this for you, what will you be like in six years? You can't expect to go through life at the express speed you developed in College. If you got practical facts flung at you in the same profusion that you received theory, you would be greyheaded at thirty, and a babbling idiot at sixty; your brain wouldn't stand it. Our atmosphere has about four parts of nitrogen to one of oxygen. Nitrogen is of no active service to us at all—it is just put in to dilute the oxygen fuel and keep us from burning ourselves out too quickly. In the same way, the drudgery of the shops is essential to us in order that we may have time to soak in the meaning of the big facts that occasionally come up against us. If you study such men of affairs as you have the opportunity of meeting, you will see that directly a man tries to do too much he becomes

Digitized by Google

irritable. He is eliminating the nitrogen, and his system won't stand the combustion. A shop foreman who was a friend of mine always used to shake his head at any man who was trying to get on in the profession too quickly. "Ah!" he would observe, "it's Christmas pudding—only Christmas pudding that does it!" He was quite right; to get experience you must put years of work in, and you can't, by worrying and fussing, cut down the number of Christmasses required. Thirty knots is good going for a torpedo-boat destroyer. Try to push the speed up to thirty-five and the boat will be all coal bunker and no engine.

Another point, are you sure you have enough to do? My experience is that so long as my nose was kept hard up against the grindstone I hadn't time to grumble. It was only when the slack time came that I had opportunity to rub that nose and make sniffy remarks about my work. This doesn't clash with my former proposition in this letter, which was directed against wild grabbing for "experience." I am now talking about continuous hard work at one job. The more occupation you can get—particularly if it is of a healthy, weight-lifting nature—the better for your spirits. Come into the shop in the morning with the intention of beating your previous output, and you will find yourself becoming so cheerful that you will want to scrap with the first fitter that reminds you that you're not on piecework.

Another thing; think about your work. The amount of attention which is necessary to carry the job through without disaster is the minimum which you should give. That is your employer's part of your brains. Now turn on the limelight for your own benefit. For instance, you have a hundred gunmetal sleeves to bore and face-up. Nothing more simple; nothing more monotonous. Yet any number of interesting points come out of the job. What is the quickest lathe speed you can use? How deep a cut can you take? Which would probably go first—the tool, the work, or the strap? (Don't be rash, however.) This brings you on to strength of materials of the machine tool if you want to get there. But there are plenty of things nearer home than that. The best rig-up, the proper rake on the tool, the best lubricant to use, the use of the turret head—plenty to think about; matter you will never find in books, but which you will use every day later on. You are gathering impressions every time you look at your job. You are doing work instead of talking about it—making friends with the iron and brass that you will some day use for your own advantage.

Finally, I would make a radical suggestion. I know that shop life is very dismal at times—that it will, in fact, play upon your health through your spirits if you let it. But as an antidote to it I would recommend you to have an evening hobby connected with engineering, but offering you sufficient change of work. I never yet knew a young man of parts who did not think that, if he had time, he could develop a career along a certain line of knowledge. Very well, devote some part of your evenings to the development of your speciality. Do not work exclusively at it, for you must make records of your general experience. But you will now do no harm by commencing to build up your special attainments on sound engineering lines, which means by slow growth. Then when you come home to tea rampant because your foreman has called you a lost, ensanguined son of a paralytic idiot, or words to that effect, for something which you know to be his own silly mistake, you will simply go for your own special work. In two hours you will not only have laughed at him and forgiven him, but you will be smoking your Navy Mixture with the calm anticipation of the time when he will crawl round your feet for a job.—Yours,

THE OLD 'UN.

FORTHCOMING EVENTS.

MONDAY, OCT. 10.

Institution of Mechanical Engineers (Graduates' Association).—At 8 p.m., paper by Mr. V. I. N. Williams, graduate, on "Exhaust System of Dust Collecting."

FRIDAY, OCT. 14.

Electro-Harmonic Society.—At 8 p.m., smoking concert. (For programme see other column.)

METHODS OF DEALING WITH MIXED SYSTEMS OF TRACTION.*

BY MR. A. L. C. FELL, M I E E., M I MECH.E, ETC., CHIEF OFFICER, LONDON COUNTY COUNCIL TRAMWAYS.

In this short paper the author only proposes to deal with the question of "mixed traction" in a very broad manner. In the majority of instances in this country, electric tramways have been installed as a development of some other system of traction, so that for a short time, at any rate, nearly every manager of an electric tramway has had to consider the question of "mixed traction." The subject may be roughly divided under the following headings: (1) temporary mixed traction during reconstruction; (2) mixed traction under normal conditions; (3) mixed traction in connection with running powers. The problem to be faced during reconstruction is a very complicated one. It is to maintain, as far as possible, a useful and fairly efficient service without incurring serious loss. The larger the city the greater the difficulty, as competing omnibus companies, tubes, underground, overhead, and surface railways are only too anxious to absorb the traffic and provide increased accommodation. In smaller cities and towns, where the tramway has practically a monopoly, the question of opposition need not be feared, but any dislocation or stoppage of the tramways is a matter of vital importance to the travelling public.

Each tramway authority has to consider the following questions before the work of reconstruction is commenced: (1) Will it be necessary to close the road for vehicular traffic? (2) What is the best method of arranging the work, so that the tramways can be kept running? (3) Can the work be carried out properly and expeditiously if a short length of single line is reconstructed, and temporary crossovers are used? (4) Will it be advisable to lay a temporary track on one side of the road and reconstruct a fairly long length of single line? (5) Will it not be better to stop the tramways? The answers to these questions depend entirely on local conditions.

In London in the majority of cases the roads have been kept open for vehicular traffic, and the tramways have with two exceptions been kept open, but the loss in receipts last year due to the disorganisation of the traffic during reconstruction amounted to upwards of £24,000. Where the tramways have been kept running, a temporary track has been laid at one side of the road. In two instances the tramways were stopped during reconstruction. In the first instance the route was an unimportant one, and electrical running was not commenced until the whole route was complete. In the second instance, one track was reconstructed at a time: when about one-third of the route was completed work was commenced on the other track; in this way half the roadway was kept open for vehicular traffic. Whenever possible, mixed traction and the necessity for changing cars has been avoided.

If the original system is a horse or a steam tramway, and it is desired to reconstruct for an overhead electric tramway system, it is advisable to complete the whole of a route before the electric cars are put into operation, and so avoid "mixed traction" if possible; but if it is a question similar to that which recently had to be dealt with in London, it is not possible. The special instance was as follows: A horse tramway originally ran from the Westminster and Blackfriars Bridges to Brixton. About 10 years ago a portion of this route was reconstructed and extended, and a cable system of traction was installed, as the gradients were considered too steep on the extension to be profitably worked by horse traction. For the convenience of the passengers the horse cars on the other portion of the route were fitted with cable grippers, so that they could be run over the whole route; the change over at the junction of the two systems being made very rapidly. In 1903 the portion of the route operated by horses was reconstructed, and a conduit electric traction system was installed. Owing to obstructions in the roadway, it was not possible to carry the conduit sufficiently far to enable the cars on the cable and electric systems

* Paper read before the Liverpool Congress of the Municipal Tramways Association of Great Britain.

Digitized by Google

to be brought close to one another, and it was necessary to draw the cable cars over the intervening space by means of horses. The original intention was to temporarily operate the electric cars over the cable system, and they were fitted with cable grippers and plough-lifting devices, but it was found that the cable was not strong enough to draw the heavy electric cars, and it became necessary to transfer the passengers from the electric to the cable cars, and *vice versâ*. As this very mixed system was very inconvenient and expensive, it was arranged to reconstruct and electrify the cable portion on the conduit system. The cable had to be stopped during reconstruction, and the question of operating the cars by horse traction was discussed, but as four horses would have been necessary to draw each car, it was decided, after very careful consideration, to stop the tramways altogether during reconstruction, but to allow the ordinary vehicular traffic to use one-half of the road, as the thoroughfare was a very important one. The work was carried out in this manner, and not only was a very heavy loss on the disorganised working prevented, but it was possible to open the first portion of the road in 6½ weeks, and a second portion in 1½ weeks, and the remainder in three weeks, or a total of 3½ miles of double track in 11 weeks from the date on which the cable tramways stopped running. The result, from the traffic point of view, is that the receipts from this portion of the route have been doubled, and the receipts on the portion of the road previously reconstructed for electric traction have been increased by over 25 per cent., clearly demonstrating that a through route not operated by mixed systems of traction is what the travelling public require. The cost of operating the above route by horse and cable systems was 9·99d. per car mile. The cost of operating by electricity, horse, and cable was 7·92d. per car mile. The cost of operating by electricity only is 7d. per car mile, including all charges for power supply. We hope that when we obtain the necessary power from our permanent generating station at Greenwich that the cost of operation will be reduced to less than 6d. per car mile.

Some municipal authorities may think it advisable to permanently operate several different systems of traction, and under special circumstances this may be the best policy to adopt, although as a general rule a uniform system is most easily and efficiently worked. Taking London as an example, where mixed traction has been somewhat freely used and will still be used, although only to a limited extent, horse, cable, and electric traction have all been in operation at one time, and in one instance already mentioned the whole of these systems were for a short time in operation on one route. The London County Council has abolished the only cable line which it possessed, and the majority of the horse lines in the south of London have been reconstructed and are now worked on the conduit system. The remaining lines will very shortly be dealt with, and reconstructed either on the conduit or the overhead trolley system. If necessary, the Council will not hesitate to mix these two systems. The complications introduced present no insurmountable difficulties to the management, as the method of changing from one system to the other is very simple and expeditious, the whole operation being carried out in about 15 seconds. The conduit plough has simply to be wound up by a winch and the trolley arm is released, and the trolley placed on the overhead line, the only drawback being that cars have to be fitted with both trolley standards and plough carriers; in other respects the equipment of the cars is identical. In London, in all probability, the conduit system will be installed in all crowded thoroughfares and on every route which can be profitably operated. I only hope that as time goes on we shall be able to materially decrease the cost of construction on the conduit system, and also reduce the cost of operation, so that practically the whole of the London County Council's tramways may be on the conduit system. For London, I am convinced that the conduit system is the ideal system, and the only one that is likely to prove an unmixed blessing.

The London County Council are now constructing a shallow tunnel on the north side of the river between Southampton-street and the Victoria-embankment. This tunnel will form the main connection between the Council's northern and southern tramways as soon as parliamentary powers are obtained for lines over Westminster and Blackfriars Bridges and along the Victoria-embankment. It will only be possible to work single-decked cars through this tunnel, as it is only 13ft. high. It will be necessary, so that full advantage may be taken of the tunnel, to run through cars from one end of the system to the other. To do this the majority of the cars will have to be of the single-deck type with vestibules, which can be either open or closed, in which passengers desiring to smoke can be accommodated. The double-deck cars will be used for short-distance journeys, and on other than through routes.

Local difficulties with regard to "mixed traction" may be easily dealt with. Special routes can generally be arranged on which each system may be operated, but "mixed traction" is a more serious question when through running over tramways belonging to outside authorities is contemplated, as not only have different systems to be dealt with, but the subject of standardisation has to be faced. Unhappily, up to the present time there has been no uniformity; the so-called standard gauges are not identical. The sections of rails vary greatly, and in several instances the dimensions of the cars vary to such an extent that, although the rails may be laid to a standard gauge, a sufficient clearance cannot be obtained between the cars. A great deal is at present being done with a view to standardising where possible, but it will be a very long time before these standards can be introduced—in fact, I very much doubt if the standards will ever be uniformly adopted in this country. In numerous instances the authorities have decided to continue the development of the local tramway system, so that the various parts of the undertaking will be interchangeable. This can quite readily be understood when it is considered that when the majority of the undertakings were started no definite standards were recognised, and each pioneer authority had to make its own standards.

If any members of this association wish to realise to what extent traction can be mixed I would recommend them to visit Paris. A short time ago I saw no less than 12 systems of traction in operation in Paris in one day. The systems were as follows: (1) conduit; (2) overhead trolley; (3) accumulator; (4) steam cars drawn by locomotive; (5) superheated steam cars; (6) gas cars; (7) oil cars; (8) horse cars; (9) Diatto surface-contact system; (10) Dolter surface-contact system; (11) tube railway, third rail; (12) electric locomotive drawing ordinary steam railway trains into passenger station.

Taking the first 10 on above list as an example of what may be done on any tramway undertaking, the following arrangements might be made: The conduit cars could be run over the trolley, surface-contact, and accumulator systems, but to do this the cars would have to be fitted with ploughs, trolley standards, and accumulators. In certain cities in Germany the cars are equipped with both trolleys and accumulators, as overhead traction is not permitted in the most important thoroughfares; but I understand that the cost of operation is abnormal, and the working is very unsatisfactory. In my opinion it would be less expensive to instal the conduit system in the restricted area. In Paris the overhead and conduit systems are extensively used in conjunction with one another, and the results are most satisfactory. I understand that a similar mixed system in Bournemouth also works satisfactorily. There would be no difficulty in fitting up cars for trolley and surface-contact systems, but I am afraid that it would be a more complicated matter to equip cars for the conduit and surface-contact systems, as the plough and the necessary lifting gear takes up all the available space between the motors, and the surface-contact skates would have to be divided and very short. Horse, steam, gas, oil, and other self-contained systems might be operated on any of the other systems, but the electrically-equipped cars would be useless on the lines operated by these systems unless the routes were electrically equipped throughout.

Attached hereto will be found a tabulated statement to the list of queries which I circulated amongst the members of the association with a view to ascertaining what is being done with regard to "mixed traction" under various conditions. It will be noted that nearly every local authority

Digitized by Google

has tried to avoid "mixed traction." It appears that very few authorities stopped running the tramways during reconstruction.

In the majority of cases, short lengths of single line have been reconstructed, and temporary cross-overs have been used to keep the tramways open. Very few instances are given where through "mixed traction" is in operation on the same route. The answers to some of the questions seem to denote that they have not been quite clear. This is especially noticeable with regard to Question 10. Under this heading, it was simply the items of "gauge" and "clearance" about which information was desired, and not about running powers.

QUESTIONS AND ANSWERS.

1. Have your tramways been reconstructed for electric traction?
   - 34 Corporations: Yes.
   - 12 Corporations: No.
   - 5 Corporations: Part of the lines.
   - 3 Corporations: Electric traction was the first system.
   - 1 Corporation: Lines now under construction.
2. Was the work done by contractors?
   - 18 Corporations: Yes.
   - 14 Corporations: No.
   - 14 Corporations: Partly by corporation and partly by contractors.
3. During reconstruction—
   (*a*) Did you stop the ordinary vehicular traffic?
   - 12 Corporations: Yes.
   - 34 Corporations: No.

   (*b*) Did you stop running the tramways?
   - 15 Corporations: Yes.
   - 24 Corporations: No.
   - 3 Corporations: Only in a few instances.

   (*c*) Did you close the roads altogether?
   - 6 Corporations: Yes.
   - 34 Corporations: No.
   - 1 Corporation: In a few cases.
   - 1 Corporation: Only track portion.
   - 1 Corporation: Not all; some side roads.
4. If you continued running the tramways, did you reconstruct one track at a time:
   (*a*) With temporary cross-overs?
   - 23 Corporations: Yes.
   - 5 Corporations: No.
   - 7 Corporations: Yes.
   - 4 Corporations: No.

   (*b*) With a temporary track laid at one side of the road?
   - 8 Corporations: Yes.
   - 1 Corporation: Yes, in one case.
   - 10 Corporations: No.
   - 1 Corporation: Yes, for single track.
5. Have you more than one system of traction in operation regularly? If so, please give particulars.
   - 6 Corporations: Yes.
   - 44 Corporations: No.
6. Do you run through cars over more than one system?
   - 8 Corporations: Yes.
   - 35 Corporations: No.
7. If so, how do you operate the cars?
   - 1 Corporation: By lifting plough from conduit and connecting trolley arm.
   - 1 Corporation: The horse cars were fitted with cable grippers.
8. On a route where more than one system of traction is in operation, do passengers change cars at the end of each system?
   - 4 Corporations: Yes.
   - 6 Corporations: No.
   - 1 Corporation: Except in one case.
9. If so, do you issue through transfer tickets?
   - 2 Corporations: Yes.
   - 1 Corporation: Yes, in one case.
   - 9 Corporations: No.
10. If outside authorities or companies have running powers over your lines, have you experienced any difficulty?
    (*a*) With regard to the gauge of the track?
    - 19 Corporations: No difficulty experienced.

    (*b*) With regard to the clearance between the cars?
    - 19 Corporations: No difficulty experienced.
    - 1 Corporation: Difficulty anticipated in one instance.

'E DON'T KNOW WHERE 'E ARE!

BY SIMPLEX.

Alderman Boyd, of the Southwark Borough Council, has dissolved into airy nothingness the whole fabric of electrical engineering. "Properly speaking," he is reported as saying, "there is no such thing as an electrical engineer. Any person of ordinary intelligence could read up in a month all that an electrical engineer knew. There is nothing in it."

Wot cher! Hev yer seen an engineer a knockin' rahnd abaht this wye?
Nice cove—got a dyzed egspresshun on, like a dorg wot's gorn astrye!
Used ter be M.I.E.E. an' sitch et cetterrar—
But Mister Boyd says that that's all tommy-rot, so 'e don't know w'ere 'e are!

'Ard lines! Never sees a piper now, except perraps the *Dily Mile*.
Used ter! Took the *Electrician* in an' read it reg'lar without fyle!
Nah 'e knows 'e's bin done in, and buys the *Evenin' Star*;
For Mister Boyd says that Science is a suck, so 'e don't know w'ere 'e are!

Wot ho! Got the blooming 'ump, 'e 'as; an' mourns a stoopid misspent life!
Worked so 'orrid 'ard to train hisself, 'e 'ad'nt time ter kiss his wife!
Nah 'e knows 'is chump is soft—for it on'y tikes an 'arr
Ter learn the whole of electricity—so 'e don't know *wot* 'e are!

Oh, lor! Mister Boyd, I reely think yer've bin an' gone an' done it nah!
One word—an' all the crard of engineers must find their 'ats an' mike their baah!!
Don'tcher think yer impidence a bit pecooliar?
An' w'en yer'e next in the Borough Council room, jest remember *w'ere* yer are!

CLEANLINESS VERSUS INSULATION.

(Founded on a Recent Incident.)

This is a tale of blood,
Of blood and soap combined,
That in a watery flood
The shop wires undermined.

A butcher's shop the scene:
The butcher clove his meat;
The shop well washed had been,
The butcher had wet feet.

Till, with a sudden yell,
His steel he flung aside;
He merely gasped "Oh! Heavens,"
And fled all terrified

Unto the local Works,
And told the smiling Chief
In spasms, fits, and jerks,
"Your 'lectric's on my beef."

The Chief he sent in state,
With Eversheds and pliers,
For to investigate
And mend the faulty wires.

On mutton, beef, and ham
Was juice at many a volt;
Who touched them said "Oh! Heavens,'
And skittered like a colt.

And now, with wary touch,
The mains man roves the stock
Here slightly, there it's much,
Here comfort, there a shock!

By paths of painful pang
He traced the errant juice
O'er fields of flesh and *sang*
It made conductive use.

Until he found the spot
Where blood and soapy brew,
With brooms and water hot,
Those leads had rotted through.

Moral: Butchers' shops require special wiring precautions.

THE SPEED REGULATION OF THREE-PHASE MOTORS BY POLE CHANGING.*

The regulation of three-phase railway motors by changing the number of poles seems to be increasing in importance (*vide* the new locomotives for the Valtelina Railway, etc.), so that the following discussion of the subject will be of interest. It will be assumed that the motors are drum-wound, and that the speed reduction required is as 2 : 1. In order to determine the relative qualities of the various possible arrangements, the following points must be considered: (*a*) the field curve, which is better the nearer it approaches to a sine curve; (*b*) the flux, Φ, because of its effect on the iron losses in the stator yoke; (*c*) the maximum

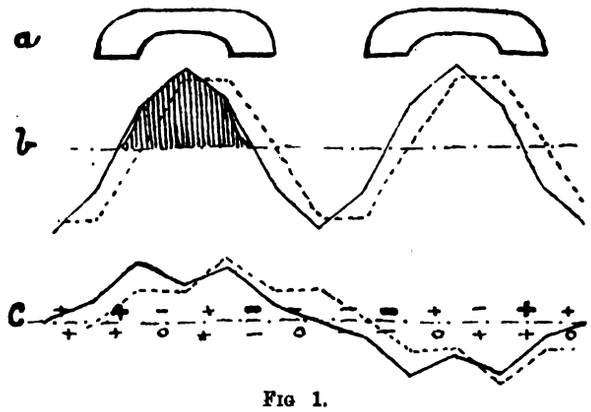

FIG 1.

air-gap flux density, $B_{max.}$, because of its effect on the magnetising current, J_μ, and on the iron loss in the teeth; (*d*) the magnetising current, J_μ, itself, because, besides depending on the maximum flux, it also depends on the greater or less amount of interaction between the separate phases; (*e*) the leakage, because on it depends the overload capacity of the motor.

In order to avoid considering every possible number of slots separately, a uniform smooth-cored winding will be assumed in all cases. This assumption is very nearly correct with even as few as three slots per coil side, and is in any case much more correct for the ordinary motor than the assumption of a single slot for coil side. The voltage will, for simplicity, be assumed to have a sine form, as with this shape, neglecting hysteresis losses and saturation, the

FIG. 1D.

magnetising current is also of sine form, and has the relative values of 1, −·5, and −·5 in the three phases at a given instant, and of ·866, 0, and −·866 at an instant one-sixth of a period later. The curves of magnetising current (and of ampere-turns) for these two instants are shown full and dotted, respectively, in the following curves. Neglecting saturation, these curves of magnetising current will also represent the air-gap induction, and their highest ordinate will be the required maximum density ($B_{max.}$ for the full line, and $B'_{max.}$ for the dotted line). The area of the curves also represents the total flux, Φ and Φ', at the two instants. For greater simplicity two groups of winding arrangements will be distinguished: (*a*) those having one coil per pair of poles per phase, and (*b*) those with one coil per pole per phase (considering the larger number of poles in each case). After changing over to the smaller number of poles this will give one or two coils per pole per phase respectively. A further distinction may also be made with regard to the way in which the coils are connected together: (A) with the same coils in one phase for both numbers of poles, or (B) with different coils in one phase for the two number of poles.

Group Aa.—To this group belongs Dahlander's method (*Elektrotechnische Zeitschrift*, 1897, p. 257), consisting of a standard coil or bar three-phase winding, but with narrow coils (coil side = one-third of the (smaller) pole-pitch). (See Fig. 1A.) For forming the smaller number of poles every alternate coil in each phase is reversed. The field curves for the two numbers of poles are shown in Figs. 1B and 1C respectively. The shaded portion in Fig. 1B represents the voltage induced in the winding, differing from the field curve only in having parabolic sides to allow for the fact that the whole flux is not looped with the whole of the turns. Calling the induced voltage 1, the turns per phase per magnetic circuit (with the larger number of poles) 1,

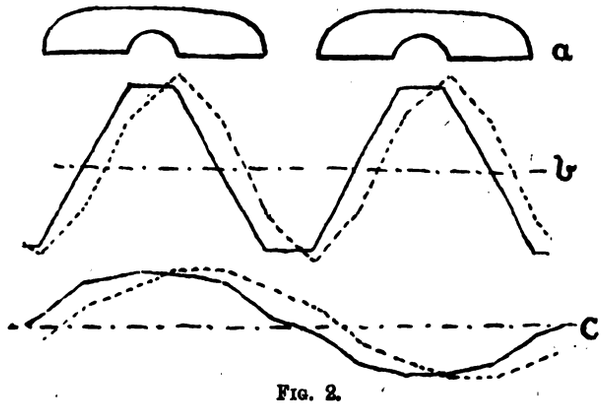

FIG. 2.

and the pole-face area (with the larger number of poles) 1, the relative results shown by the curves Fig. 1B and Fig. 1C are:

No. of poles.	$B_{max.}$	Φ.	$B_{max.}$	Φ.	J_μ.
2 *p*	1·8	1·05	1·56	1·04	·9
p	1·23	1·36	1·42	1·42	·41

The leakage and overload capacity have still to be dealt with. In this case, and in most of the other cases to be considered, the changing of the poles has little, if any, effect on the leakage, consequently the short-circuit current will

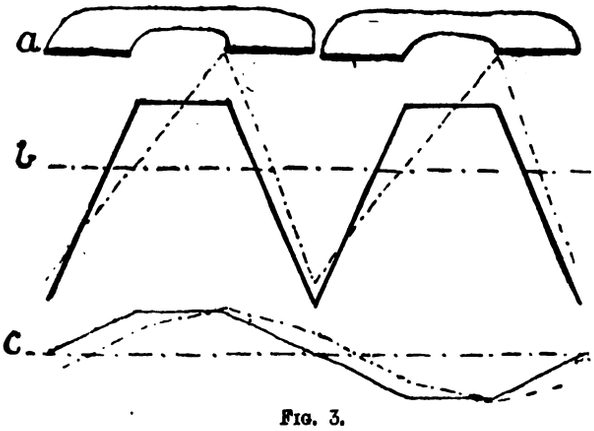

FIG. 3.

remain the same for both numbers of poles so long as the voltage is unchanged. The circle diagrams for the two cases will, therefore, be as in Fig. 1D, the maximum ordinate which is proportional to the maximum power obtainable being almost the same as both the speeds. In other words, the motor can develop about double the torque at the lower speed, and is, therefore, comparable with a direct-current series motor. It is, of course, possible to increase the torque at the higher speed by coupling the coils in parallel instead of in series, but this involves increasing the iron sections.

The saddle-shaped top of the field curve (Fig. 1C) can be improved by employing broader coils (coil side = $\frac{2}{3}$ of the (smaller) pole-pitch), as shown in Fig. 2A. Such a winding would have to be carried out similarly to a direct-current winding or bar winding, coils of different phases being partially superposed in the same slots. The resulting

* Abridged translation of an article by J. K. Sumer in the *Zeitschrift für Elektrotechnik*, June 26, 1904.

Digitized by Google

curve shapes are shown in Figs. 2B and 2C, and the other particulars in the following table:

No. of poles.	Bmax.	Φ.	B'max.	Φ'.	Jμ.
2p	1·8	1·2	2·08	1·21	1·2
p	1·125	1·46	1·17	1·49	·45

The saddle-shaped top of the field curve can also be avoided by spreading the coils out more, so that the coil-pitch is, say, $\frac{4}{5}$ of the (smaller) pole-pitch. With narrow coil sides ($\frac{1}{3}$ of the pole-pitch) this would result in only half the space being utilised, but with broad coil sides ($\frac{2}{3}$ of the pole-pitch) the results shown in Fig. 3 would be obtained.

As the coil-pitch is increased beyond the smaller pole-pitch and approaches the larger pole-pitch, the results obtained naturally become less satisfactory for the low speed, but better for the high-speed connections. This is made evident by the unsymmetrical nature of the field curve and by the unsatisfactory results shown in the following table for this case:

No. of poles.	Bmax.*	Φ.	B'max.*	Φ'.	Jμ.*
2p	3	1·33	2·6	1·3	1·5
p	·9	1·2	1·04	1·21	·3

* The total area of the positive and negative flux waves have naturally to be alike, and the zero line has been drawn to suit this. The Bmax. column contains the actual top value from the curve, as that decides the teeth losses, but the magnetising current, Jμ, has been calculated for the average between the pointed flux curve and the flat-topped flux curve.

Group Ab.—This group contains windings with one coil per pole per phase, and with the same coils forming one phase with either number of poles. The author discusses the various possible arrangements, and shows that in every case better results are obtainable with the corresponding Group AA arrangement.

Group Ba.—This group refers to motors in which different coils form a given phase with the two numbers of poles, and in which there is only one coil per phase per pair of poles. This group also, on investigation, proves to be less satisfactory, both as regards uniformity of field and as regards the flux and magnetising current values, than the corresponding arrangements of Group AA.

Group Bb.—To this group belong windings having one coil per pole per phase, coupled up with different coils in a given phase for the two number of poles. The group has the serious disadvantage of requiring a large number of change-over leads and terminals, so that although one or two of the arrangements show slight improvements in flux density and magnetising currents as compared with Group AA, these improvements are not sufficient to justify the increased complications.

THE RELATION OF THE HYPOTHESIS OF COMPRESSIBLE ATOMS TO ELECTRO-CHEMISTRY.*

BY PROF. T. W. RICHARDS.

Theoretical electro-chemistry may be divided into two closely related sections—that which treats of the phenomena at the electrode, and that which treats of the phenomena in the unchanged electrolyte. The former of these sections is the more important practically, and is likewise a more certain domain theoretically.

In the first place, then, one may ask: How would a compressible atom behave on leaving an electrode and going into solution as an ion? It would then be attacked by an entirely new set of affinities, being in its new position surrounded by molecules of the solvent, instead of by atoms similar to itself, and those new affinities exerting new intensity of pressure would be expected to change its volume. Moreover, the solvent being itself in part exposed to new internal pressures would also change in volume. As a matter of fact, a marked change of volume is always observed when a positive and negative element go into solution in the ionised condition. For example, a litre of a normal solution of potassic chloride occupies 43 millilitres less space than the solid potassium, liquid chlorine, and water, from which it may be made; the change of volume in the common salt is 31 millilitres, and that in the case of lithic chloride 17 millilitres. Potassic bromide in the same way gives a contraction of 33 millilitres. Among these similar compounds and in many other cases it usually appears that the greater the electrical potential afforded by the double ionisation the greater the change of volume; also, the greater the compressibility of the elements concerned the greater the change in volume. It is worth while also to call attention to the fact that these changes of volume on ionisation seem to be approximately parallel with the changes of volume on forming the corresponding hydroxides; just as the heats of ionisation are approximately parallel with the heats of formation of the hydroxides. This parallelism may indicate that the effective agency causing ionisation or galvanic solution of a metal is the attraction of the metal for the oxygen or the hydrogen of water—most probably the oxygen.

Although these regularities are fairly prominent on comparing the properties of similar elements in a natural group, exceptions are not hard to find on comparing very dissimilar substances. Reason for these irregularities may partly be found in the extremely complex mathematical relations which must obtain if the atom is really compressible; but, probably, at least, a part of the exceptions may be traced to the expected simultaneous contraction of the solvent already predicted. That the solvent really often contracts is manifest from the fact that in some cases (notably the hydroxides of lithium, sodium, and barium, and the sulphates of zinc, cobalt, nickel, and magnesium) the solution occupies less space than the water alone from which it is made. In this connection it is worth while to call attention to the well-known fact that during the formation of 18 grm. of water from its ions in the neutralisation of a strong acid by a strong base, an increase of volume of 20 millilitres occurs, an increase greater than the volume of the water formed.

Although by no means all possible cases can now be studied, because of lack of data, there is good reason to believe that in all cases both the solvent and the dissolved substances change in volume under the readjustment of internal pressures of ionisation, and the resultant effect is so complicated that it is impossible at present, except in the most exaggerated cases, to determine the mode of the distribution of the change. Nevertheless, since changes of volume actually occur on ionisation, and since in the more marked cases this volume-change seems to correspond roughly to the known compressibilities of the substances and to the free-energy change during the reaction, the theory of compressible atoms is supported. At least, even supposing that the explanation herein given is rejected, the theory is here able to call attention to an interesting series of facts concerning volume-change, which must receive an explanation before a complete interpretation of the nature of a dissolved electrolyte is obtained.

Another less direct relation of the theory of compressible atoms to electro-chemistry is to be found in the effect of change of volume of reacting systems upon their specific heats. Thomsen pointed out long ago that a contraction in a reaction between aqueous solutions is usually accompanied by a loss of heat capacity of the reacting system; and it is possible to cite many other cases in which this is true. Probably, however, the cause of this loss is not so much the decrease in volume as the irregular stress caused by the simultaneous presence of very different affinities. In terms of the hypothesis of compressible atoms, atomic distortion seems to cause a diminution of heat capacity. As a kinetic conception this interpretation is plausible.

The relation of this change of heat capacity to electro-chemistry is very important. Recent study has made it appear highly possible that a change in heat capacity during a reaction is the chief, if not the only, reason why the total energy change (or the heat of the reaction) is not equal to the electrical work which the reaction performs in a galvanic cell. In colloquial language, the heat energy which is displaced or forced out by a diminution of heat capacity does not seem to be able to perform work. If this be true, change of heat capacity is responsible for the "bound energy" of a galvanic cell, and therefore, according to Helmholtz's equation, for its change of potential with the temperature. If, further, the preceding conclusion,

* Abstract of paper presented before Section C of the International Electrical Congress of St. Louis.

Digitized by Google

based upon the theory of compressible atoms, be also accepted, the fundamental cause of this temperature coefficient of the E.M.F. is referred back to atomic compression and distortion, which diminish the possibility of heat vibration in the compressible atom.

One essential condition of ionisation has not yet been dwelt upon—namely, the relation of ionisation to the quantity dimension of electricity. Recent investigation has shown that Faraday's law is not merely an approximation, but is rather one of the most exact of the laws of Nature. If the atomic theory be accepted, one must therefore admit that each similar atom, on ionising into a liquid, receives or releases exactly the same charge, which is a precise simple multiple of a given unit. What, now, does this unit of change signify? In other words, what are the essential attributes of electrical quantity, and what explanation for this exact and fundamental law can be found in the theory of compressible atoms?

To the electro-chemist who has nothing to do with electrical capacity, the quantity dimension of electricity is important merely as a number. He recognises it only because it is proportional to equivalent weight of deposited metal, or to equivalent volume of evolved gas. Still more simply it may be said to represent to him nothing but the number of atomic contacts which are made or broken in a given reaction. Therefore, the electro-chemist attempting to discover the relation of the compressible atom to galvanic deposition naturally first seeks to imagine what would happen to a compressible atom on making or breaking a firmly united atomic contact with another atom.

Evidently for each union with other atoms a given atom would give and suffer a shock of impact or combination. The exact effect of this shock upon the atom itself cannot be determined, but if the atom is compressible throughout, many forms of vibration or temporary rhythmical distortion might be possible because of the shock. One of the most probable forms is perhaps a vortex motion; and it will be seen that this form lends itself best to further interpretation. If the atom were perfectly elastic, such a vortex would continue to exist indefinitely when once formed. Let us imagine, then, that each collision of atomic combination starts or transfers a vortex or some other form of self-perpetuating shock. Then the deposition of a given number of chemical equivalents will result in the transfer of a given number of shocks, or a given quantity of electricity; and Faraday's law is explained. In short, in order to conceive logically of this law, one need not ascribe weight or mass to the electron—permanent vortex will represent the needed unit as well as a ponderable particle. But only a compressible atom could hold or carry such an infinitesimal vortex, hence this hypothesis is dependent upon the hypothesis of compressible atoms.

This easy explanation of Faraday's law without a material conception of electricity leads one to enquire whether or not other relations of electricity might not likewise be satisfied by a vortical conception of the unit of electrical quantity. A complete study of the details of this possible explanation would be out of place, but a few of the electrical properties of substance may be mentioned in this connection. For example, the electrical conductivity of solids is in many cases what it would be expected to be if their atoms were compressible. Atomic distortion would be expected to interfere with the ready transference of the vortices. The simpler the crystalline form the less distorted would be the individual atoms, and the more easily would the vortices be received and transmitted from one atom to another. On the other hand, with irregular atoms permanently distorted by chemical affinity, the uneven structure would receive and transmit the vortices less easily, and the potential energy of the mutual repulsion would be converted into heat. As a matter of fact, the two best electrical conductors among metals, silver and copper, crystallise in the regular system, and the poorest solid conductors among pure metals, bismuth, antimony, and arsenic, are of less symmetrical crystalline structure. The non-metals, which are all poor conductors, are still more noticeably complex in symmetry, and such non-conducting substances as bromide and iodine must be very much distorted in atomic shape if their atoms are compressible, because these atoms must be much compressed on one side by their firm union to form the diatomic molecules, and only slightly compressed on the other sides by their feeble cohesion, indicated by great volatility. The relatively slight conductivity of alloys and compounds points in the same direction, for heterogeneity of atomic structure would imply irregular internal pressure, great atomic distortion, and hence poor conductivity. The considerable effect on conductivity of even slight impurity in a metal, and the extremely low conductivity of substances like glass and cellulose, are well known, and accord with this interpretation.

Again, it is easy to see how increased thermal energy, which, if atoms are compressible, must be supposed to exist as a simpler oscillation of a portion of the atomic centres, would interfere with the reception and transmission of this new vortex motion, and hence to see why the conductivity of solids should decrease on raising the temperature. Moreover, one would expect the slightly-distorted atoms, easily receiving the electrical vortex, should usually likewise transmit more rapidly the simpler oscillations of heat energy, which is a fact. In applying the vortex idea to the statical and magnetic manifestations of electricity, one must imagine the vortex to cause stress in the surrounding wave-bearing medium, giving rise to the repulsion of similar vortices. Such a stress must be imagined whatever conception one forms of the electron, and is at least as easily conceivable from a vortex as from a small particle of matter.

The explanation of the brilliant experiments of J. J. Thomson and his pupils on the basis of the vortical electron is possible, if one admits, as Thomson is quite willing to do, the existence of electrical inertia independent of gravitational effect. In this case the cathode ray is to be considered as a collection of disembodied vortices, which may only be driven through the wave-bearing medium under the stress of great difference of potential. Another alternative must be adopted if one doubts the somewhat complicated evidence concerning the relative masses of the cathode corpuscle and the atom, and believes the two to be identical. In this case it is necessary to imagine that a single atom can receive many vortices under the peculiar circumstances attending the cathode discharge—*i.e*, that it is polyatomic.

Other possible relations of the hypothesis of compressible atoms to electro-chemistry, and to the new and surprising facts of radioactivity, might be pointed out, but these examples will serve the present purpose. The object of this paper has been to show that the hypothesis is a suggestive one, because it views well-known phenomena from a new standpoint, and therefore may excite the imagination into devising new methods of experimental attack. The discovery of the probable relation of the change of heat capacity on the temperature coefficient of a galvanic cell is among the new relations to which this hypothesis has already led.

The long-continued illusion of phlogiston, supported by eminent minds not much over a century ago, is enough to show the danger of a one-sided scientific consciousness, and the familiar conception of inflexible atoms may also to a less degree lead the literal mind into an intellectual rut. Of course, no claim is made that the hypothesis of compressible atoms represents truly the actual fact; indeed, atoms in any shape are an imaginary conception, which may have no counterpart in reality. Even if the thinker progresses no farther than to admit that, provided atoms exist, they may be elastic and compressible, he has broadened the train of his thought and enlarged the realm of his imagination.

It has been claimed by a few that any hypothesis is harmful, but some of the most brilliant of scientific workers have used them as a continual inspiration. Faraday, one of the greatest of pioneers, dreamed thousands of such scientific day-dreams. To him these were nothing but a benefit; for although led on by visions he knew well the difference between substance and shadow. He never confounded hypothesis with fact; and when new facts overthrew a favourite imagination, he would discard the latter gladly, rejoicing that it had led him to the discovery of new truth.

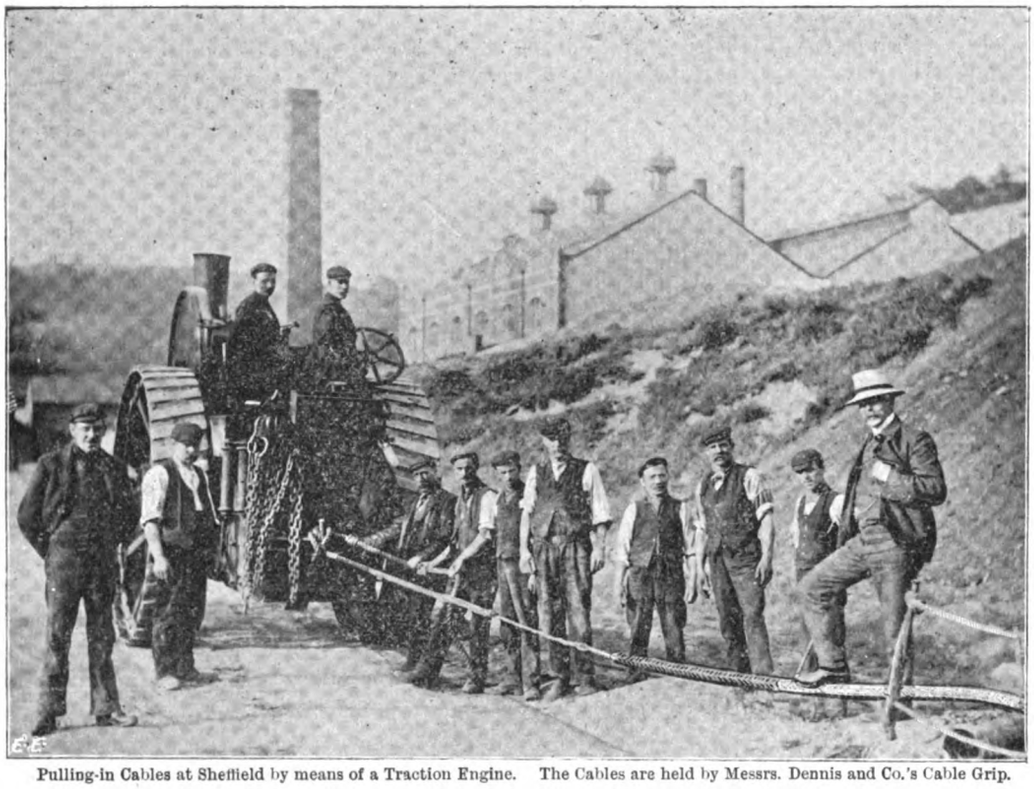
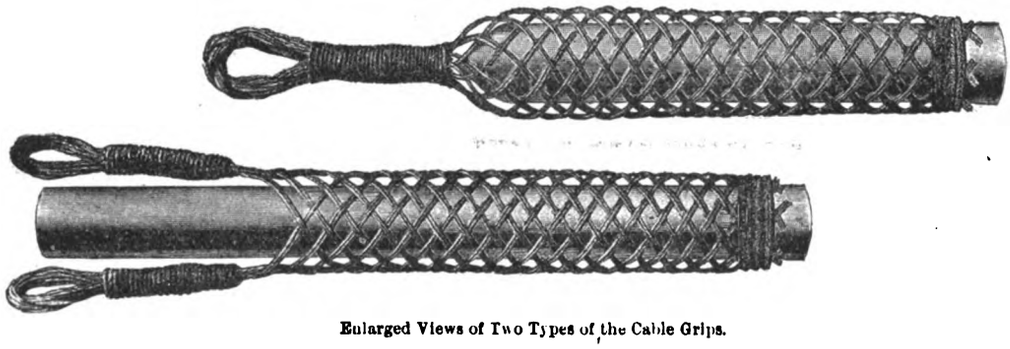
TRADE NOTICES AND NOVELTIES.

A Useful Attachment for Cable-Drawing.

A novel manner of drawing cables at Sheffield is brought to our notice by Mr. Rowland Hibbins, of the Corporation electric supply department. The photograph depicts a feeder cable being drawn with a Felten and Guilleaume cable grip attached to a powerful traction engine. Most engineers will at once appreciate the enormous strain upon the grip, which holds on with such tenacity that either the rope or the cable will have to give way before a failure in drawing can occur, as, on account of the construction of the grip, the greater the pull the more securely it holds. The great feature of the grip is that no hand, mechanical, or soldered connection is made with the cable, but it is gripped uniformly by the pliable sheath, which, when expanded, automatically locks itself. Mr. Hibbins hopes, by giving publicity to the great utility of the grip, that other engineers to corporations and supply companies may share with him in the benefit he has derived from its use, and although he has put the grips to the severest strains, they have given every satisfaction, and come out of the ordeal with great credit to the manufacturers. We may add that the grips can be obtained from Messrs. W. F. Dennis and Co., 49, Queen Victoria-street, E.C.



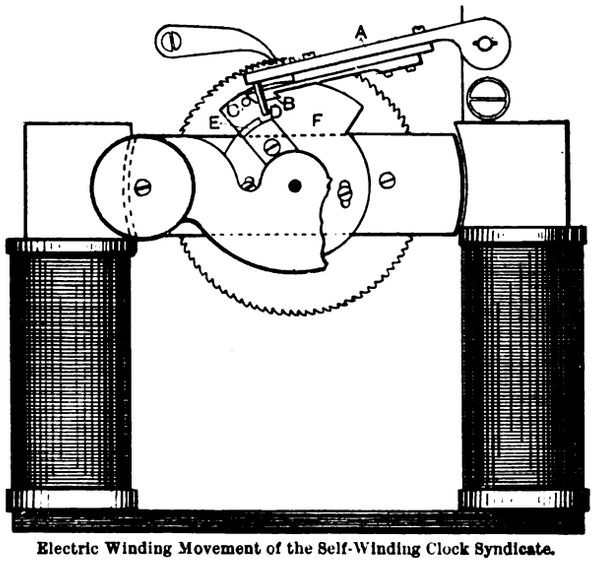
Pulling-in Cables at Sheffield by means of a Traction Engine. The Cables are held by Messrs. Dennis and Co.'s Cable Grip.



Enlarged Views of Two Types of the Cable Grips.

Self-Winding Clocks.

The Self-Winding Clock Syndicate, of 27, Audrey House, Ely-place, E.C., have designed a pretty device for the electric winding of a clock from two dry cells. The idea is not new, but the details are interesting. The electrical movement is illustrated in Fig. 1. The self-winding is actuated by an electric magnet, between which an armature is pivoted so that it can swing. To this a pawl is attached, which engages a ratchet wheel connected with the gear train of the clock, and a spiral spring attached to the armature draws it slowly out of line with the magnet poles, and thus drives the clock. The electrical contact is made about once every seven or eight minutes, and as the current energises the magnet the armature is drawn back to its horizontal position against the tension of the spiral spring. To ensure continuity during the fraction of a second occupied by this action, the clock movement is driven by a second small spring, which is put under tension by the movement of the armature itself. The contact is made as shown in the detail sketch. One terminal, E, consists of a metal segment which is carried on a plate, F, secured to the armature. The other terminal, D, consists of a pin which is secured to a swinging arm, A. Fastened to this arm, but insulated therefrom, is a flat spring, provided at its free end with a head or cam, B,



Electric Winding Movement of the Self-Winding Clock Syndicate.

adopted to engage a pin, C, on the plate, F. The ends of the cam, B, are bevelled, as illustrated, so that when the

Digitized by Google

armature moves away from the poles, the cam will ride over the pin, C, lifting the contact pin, D, out of engagement with the segment, E. When the pin C passes the inner end of the cam, the pin D will drop on to the segment, B, completing the circuit through the magnet coils, and causing the armature to swing back, and the cam then riding under the pin C will press the terminal D down against the segment, E, ensuring a perfect contact. Both the contact surfaces are of platinum. One of these clocks has been tested at the Charlottenburg Institution, and from the report received we gather that about 0·017 of an ampere-second is used at each contact. The two dry batteries provided can easily supply this for a long time. After 13 months' trial the voltage of each of the two cells used had fallen from 1·51 volts to 1·41 volts. This resulted in a decrease in the movement of the armature at each contact, and a consequent decrease in the period between successive windings. The period in question fell from six minutes on Nov. 13, 1902, to 4 minutes 48 seconds on March 16, 1903.

Catalogues, etc.

ELECTRIC HEATING APPARATUS. Isenthal and Co., 85, Mortimer-street, Cavendish-square, W.—Section 1 contains appliances for domestic purposes and use in private houses, nurseries, hotels, and clubs for heating and cooking. Section 2 is perhaps the most interesting as it describes appliances for technical purposes in factories and laboratories. Among these we note electrically-heated soldering bits, glue-pots, melting-pots, hot-plates, cauldrons, warm-water reservoirs, and large immersion heaters. In each case particulars are given as to dimensions, capacity, consumption, weight, and price.

HAULING PLANT. Lahmeyer Electrical Company, Limited, Bank-buildings, 109-111, New Oxford-street.—We have received an illustrated pamphlet describing electric plant designed to lift at a speed of 8m. per second 105 tons of coal out of a shaft 400ft. deep. It was laid down by the Frankfort house of the above company at the Ligny-les-Aire coal mine.

ALTERNATING REVERSE-CURRENT TIME-LIMIT RELAY. Ferranti Limited, electrical engineers, Hollinwood, Lancashire.—Catalogues Nos. 9 and 10, for automatic switches, moving-coil instruments, edgwise type, for continuous currents.

"E.V." ENCLOSED ARC LAMP. Union Electric Company, Limited, 151, Queen Victoria-street, E.C.—We are informed that this lamp burns for 100 hours with 1ft. of carbon. It is a successor of the firm's old D.V. pattern arc lamp, that has been largely used both for public and private illumination throughout the country. The improvements consist chiefly in the diminution of the size without decreasing the burning hours, and other improvements, such as making the fit of the globe easier, while the price of the lamp is considerably less. The company report numerous sales of these lamps, and they supply also lamps 3½in. longer than those shown in the list—viz., 2ft. 3½in.—which will burn for 200 to 250 hours with 18in. of carbon, and a range of lamps with single enclosure and ornamental design, with about 70 to 75 hours' burning.

FIELD RHEOSTATS, MOTOR-STARTING RHEOSTATS. British Thomson-Houston Company, Limited.—Pamphlets Nos. 173 and 174, the former superseding June 9, 1902, and the latter No. 126, Sept. 6, 1902.

PERSONAL.

The Hereford Corporation have appointed Mr. Walter C. Kerr electrical engineer at a salary of £400 per year.

The *Halifax Guardian* says Mr. W. M. Rogerson, electrical engineer to the Halifax Corporation, having been offered a similar position under the South Metropolitan Electric Supply Company at a salary of £700 per annum, a proposal to retain his services in Halifax was brought before the Town Council. The following resolution was carried *nem. con.*: "That the salary of Mr. W. M. Rogerson, electrical engineer, be advanced from £400 to £500 per annum on Jan. 1 next, with further advances of £50 per annum on Jan. 1, 1906, and Jan. 1, 1907, subject to Mr. Rogerson entering into an agreement to remain in the service of the Corporation for a period of three years from Jan. 1 next." We understand Mr. Rogerson will accept the offer.

Mr. Lewis Slattery, of Blackpool, has been appointed tramways manager of the Oldham Corporation, at a commencing salary of £300 per annum.

We refer elsewhere to Mr. John Young's new appointment.

APPOINTMENTS VACANT.

Station Engineer, Woolwich, Oct. 7. See advertisement.

Switchboard Attendant, Stockton-on-Tees. See advertisement. Also Eccles, 24s. per week, Oct. 12.

Meter Fixer and Inspector, wages 30s. per week, 56 hours. See advertisement.

Draughtsman used to transformer design. See advertisement.

Junior Tester for calibrating electrical instruments and general factory testing. See advertisement.

Shift Engineer, Hornsey, £2 per week, Oct. 15.

Resident and Tramway Engineer, Pontypridd, £300 per annum, Oct. 12.

LEGAL INTELLIGENCE.

TRAMWAY AMALGAMATION.

In the Vacation Court on Wednesday, Mr. Justice Warrington heard an application by the City of Buenos Ayres Tramways Company, Limited, and its liquidators, to sanction a scheme of arrangement with the Anglo-Argentine Tramways Company, under the Joint-Stock Companies Arrangement Act, 1870.

His Lordship having asked how the new debentures were to be secured, **Counsel** stated that after the sale to the Anglo-Argentine Tramways Company had been carried out the petitioning company would hand over to the new company, to be formed under the scheme, certain property which included an annual payment by the Anglo-Argentine Company.

His Lordship said he wanted to see that the debenture-holders would get some substantial security in place of the present debentures.

Counsel said the debentures would be secured by a floating charge on the whole undertaking of the Anglo-Argentine Company. The companies owned rival systems of tramways, and the present arrangement was to enable the Buenos Ayres Company's lines to be electrified, when the two systems would be worked together.

His Lordship sanctioned the scheme, subject to certain formalities being carried out.

TRAMWAY CONSTRUCTION.

At the Chesterfield County Police Court on Saturday, four summonses against employés of the contractors for laying the Chesterfield tramways—the British Insulated and Helsby Cable Company—were heard. The proceedings were taken by the Newbold Urban District Council, who were represented by Mr. W. E. Clegg, of Sheffield, the ground of complaint being that the contractors had diverted the traffic from Sheffield-road up some other streets without the necessary authority. It was pointed out that in accordance with the Act consent in writing of a neighbouring authority affected had to be obtained before any road could be stopped, and in the case in question that consent was not obtained.

Mr. T. E. Ellison (Sheffield) urged on behalf of the defendants that the Council's surveyor had acquiesced in the diversion of the traffic, and led the defendants to believe that it was not necessary for the formal written consent to be obtained.

The **Chairman of the Bench** said that it was a pity two such important bodies could not settle their differences without coming into court.

Three of the summonses were dismissed, a fine of 10s. being imposed upon the excavation foreman for putting a pole across the roadway.

COMPANIES' MEETINGS AND REPORTS

WILLANS AND ROBINSON.

The ordinary general meeting was held on Wednesday at the Cannon-street Hotel, Mr. Mark Robinson (the chairman) presiding. The report appeared in our issue of last week.

The **Chairman,** commenting upon the industrial depression, observed that there had been times nearly as bad before, and the Company had passed through them unscathed; but then their speciality had a more distinct lead than it was possible to command now. The Company had no longer a monopoly of high-speed engine work, and they had also suffered from trouble which had lost them in a measure the support of some of their best and oldest friends, who at one time would have a Willans engine or nothing. The directors, aided by the action of the shareholders in adding Mr. Peache to the Board, were giving this matter their earnest attention. In his skill in design and mastery of works management his colleagues saw much hope for the future of the Company. On two points discussed at the last meeting he could reassure them. There was much criticism because trade debtors on Dec. 31 last stood for £186,000 owing, although nearly two-thirds of the amount had not been invoiced for more than a few weeks. This time the debtors stood at only £153,000, and he regretted they had not the right to claim more from such sound people as these had always proved to be. The other point referred to certain shares in other companies, taken in part payment for work under contract. They had now sold a large proportion of these shares at exactly the price at which they had been valued in the accounts. The Board had gone in heartily for all possible reductions and economies. Specific economies had been effected in standing charges, mainly in reduction of staff, at the rate of more than £10,000 per annum, irrespective of a reduction to a larger amount in the labour bill at Queen's Ferry, and of a further reduction in the staff when certain agreements for services now in force should run out. On the other side they were striving to add more remunerative branches to the business, and they had the strongest belief that after a time these combined efforts would bring back to the Rugby business much, if not all, of its old prosperity. Such new business, however, could bear no profit for some time, and must for the present be a source of actual loss. If the stress of bad times could play such havoc with an old and hitherto profitable business, such as that at Rugby, it was easy to realise how disastrous it had been to the new business started at Queen's Ferry. More than a year was lost in experiments and failures in producing an essential part of the new type of boiler, although in the end they had completely succeeded. The manufacturing difficulties were now over, but the heavy loss in keeping the works open during the long unproductive period had crippled their resources, and they could not put down the extra capital to properly complete the plant or carry on the works upon other than

Digitized by Google

a scale just large enough to entitle them to rank as a going concern. The directors were using every endeavour to dispose of the Queen's Ferry works, and negotiations were in progress to that end. The financial position of the Company was more satisfactory than at the date of the last meeting, and they hoped to set free working capital to strengthen them in several directions. The chairman concluded by moving the adoption of the report.

Mr. F W. Clarke (a shareholder) seconded the resolution.

Mr. J. C. Peache (director) believed that they must look in the future, as in the past, to the Willans engine as the mainstay of the business. He read a letter from a consulting engineer who testified to the capacity for continuous running and the high economy shown under exacting conditions by a Willans plant installed on his advice. They were also making gas-engines, which they had comp'eted to the satisfaction to the customers, and had at present on hand orders for steam-turbines amounting to 80,000 kw. They had also concluded a contract for the manufacture of Diesel oil-engines. The shareholders would, no doubt, ask when a profit was likely to be earned; but he could not suggest an early date, many orders being taken at the low prices ruling.

Two or three shareholders criticised the Queen's Ferry venture as a rash speculation.

The **Chairman**, in replying, said that the Queen's Ferry works had been undertaken so that the company might make their own boilers, and but for the initial manufacturing difficulties, which had now been surmounted, he did not think there would be much cause to regret the step. He added that of late years the conditions of the trade had changed greatly, owing to the advent of the great electrical companies, which were able to undertake contracts as a whole.

It may be added that Mr. Mark Robinson and Sir Gilbert East have accepted, *pro rata*, reductions in their remuneration, so as to provide for the salaries of the additional directors, and Mr. Arthur Lazenby, who takes an active part in the management of the business, expressed his willingness to do the same, but the shareholders fully approved the view of his fellow directors that his remuneration should remain as at present.

The report was adopted *nem. con.*

FERRANTI LIMITED.

A meeting of the unsecured creditors of Messrs. Ferranti, Limited, was held last week at Winchester House.

Mr. John Macdonald Henderson presided, and explained that the meeting had been called by order of the court, in order to obtain the consent of the unsecured creditors to a scheme of arrangement for the reconstruction of the Company, particulars of which were given in our issue of the 23rd ult. Some discussion took place with reference to clause 7 of the scheme, as to whether the word "cumulative" should remain in or not. Eventually a resolution approving of the scheme was carried unanimously.

A meeting of the preference shareholders was afterwards held, at which an amendment was moved and seconded that the word "cumulative" in clause 7, paragraph 2, be deleted, and the dividend to preference shareholders be non-cumulative.

Subsequently there was considerable discussion among the holders of first mortgage debenture stock with regard to the protection of their security in the event of the second debentures becoming enforceable. Ultimately, on the assurance of the chairman that the solicitors would see that the first debenture holders were fully protected, the scheme was unanimously approved.

ELECTRIC RAILWAY AND TRAMWAY CARRIAGE WORKS.

The sixth general meeting of the Electric Railway and Tramway Carriage Works, Limited, was held last week at the works, Strand-road, Preston, Mr. G. Richardson, chairman of directors, presiding.

The **Chairman**, in an explanation of the reduced dividend, said the trade of the country had certainly not been so prosperous as heretofore, and especially in connection with this class of business. There had also been serious competition, but two of their most serious competitors had gone into liquidation, and the works had been sold, and consequently they were now out of the running, and they must look forward to getting better prices. He did not like to prophesy, but the directors thought they would not have an unsatisfactory balance-sheet to present to them next year. One of the awkward things in connection with the business was the position taken up by the Federation of Engineers, which was, of course, the trade unions. They were now working with great zeal to do away with overtime, and also to do away with bonuses for prompt and quick delivery. This latter practically meant that a bad workman must be in a position to earn the same money as a good one, and this was one of the points which would have to be fought later, particularly in all businesses connected with engineering.

The report was adopted.

Messrs John Kerr, M.P., and R. B. Barningham, Manchester, the two retiring directors, were unanimously re-elected.

TRAMWAYS AND GENERAL WORKS.

The report of the Tramways and General Works Company, Limited, for the year ended June 30 last, to be submitted at the meeting on the 3rd prox., states that the directors have delayed calling the shareholders together in order to be able to announce the completion of the negotiations referred to below as to the Calais Tramways Company. The delay is of less importance, as the directors, having the money available for dividend in hand, were able to pay the same as an interim dividend in April last. The accounts show a profit for the year of £1,361. Adding to this £548 brought in from the previous year, and deducting £1,500, which the directors distributed as dividend in April last, there remains £409 to carry forward. The profits of the Calais Tramways Company for 1903 show an improvement on 1902, and an increased dividend was distributed by that company in January. The dividend for the past half-year has not yet been declared. The directors of the Calais Company have for some time past been in treaty for the sale of the undertaking to a Belgian company, and the resulting contracts will be submitted to the Calais shareholders for approval on Oct. 3. The directors of this company, having had an opportunity of considering the agreements, will give them their support, as they consider them to be advantageous to the shareholders. The Lombardy Road Railways Company, as in 1902, have paid a dividend of 5 per cent. on their preference shares out of the profits of 1903. There still remains a sum of £121. 10s. due to 23 shareholders, who have not yet produced the necessary documents to enable the 6s. per share to be repaid on their holdings.

NEW COMPANIES REGISTERED.

London Electrical Syndicate, Limited.—Capital, £10,000. Objects: to adopt an agreement with the London Electrical Syndicate, Limited (in liquidation), and G. Pearson, the liquidator thereof, and to carry on the business of electricians, mechanical engineers, etc.

Liens Registered.

C. C. Braithwaite and Co., Limited (Engineers, London).—£500 debentures, created Aug. 31, and dated Sept. 22, 1904, charged on the company's undertaking and property, present and future, including uncalled capital, have been registered. No trustees.

Northampton Electric Light and Power Company, Limited (23,640).—Issue on Aug. 25 of £100 debentures, part of series created June 3, 1896, securing not more than two-thirds of the subscribed share capital for the time being charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Previously issued of same series, £32,100.

Bowen's Electric and Motor Boats, Limited, London, W.C.—Lien registered Sept. 16, for £4,000 5 per cent. debentures. No trustees. Charged on the undertaking and all the property, present and future, including the uncalled capital.

Burnand Transformer Company, Limited, Manchester.—Lien registered Sept. 21, for £1,000 debentures. No trustees. Charged on the undertaking and all the property, present and future, including the uncalled capital for the time being.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Barrow-in-Furness.—The Corporation invite tenders for arc lamps and accessories. Tenders by 18th inst.

Melbourne.—The Federal Postmaster-General requires tenders for 6,000 yards of telegraph cable. Tenders by Nov. 15.

Crejour (Roumania).—The Municipality require tenders for construction and working of tramways for 50 years by Nov. 7.

Middleton.—The Corporation invite tenders for dust destructor, boilers, etc., at the electricity station. Tenders by 25th inst.

Pretoria.—The Commanding Royal Engineer at Army Head quarters, Pretoria, is calling for tenders for the electric lighting of cantonments.

Ipswich.—The Corporation invite tenders for the supply of continuous-current meters for the ensuing 12 months. Tenders by 24th inst. See advertisement.

Blackheath.—The County Council require tenders for electric wiring and fittings, etc., at the ranger's house. Tenders by Oct. 11. See advertisement.

Mexico.—The Federal District Railway Company of Mexico require tenders for the electrification of six tramway lines in the town. Applications are to be made direct.

Wandsworth.—The Borough Council require tenders for electric lighting and ventilation of Council House. Tenders by Oct. 18. Full particulars in advertisement columns.

Pangbourne.—Tenders are required for lighting the village during the coming winter, for the Pangbourne Parish Council. Particulars may be obtained of Mr. C. West, jun., clerk.

Great Western Railway.—The Directors of this Company are prepared to receive tenders for the supply of various stores from Dec. 1 next to Nov. 30, 1905. Tenders by Oct. 17. See advertisement.

Brighton.—The Town Council require tenders for the installation of electric light, telephones, and fire-alarms in the diphtheria pavilion, borough sanatorium, Bear-road, Brighton. Tenders by 13th inst.

Fulham.—The Council invite tenders for the supply and erection of a 3,000-volt main generator switchboard at their generating station, Townmead-road, Fulham. Tenders by 19th inst. See advertisement.

Almendralejo.—The municipal authorities require tenders for the electric lighting of the town for 10 years. Particulars may be obtained from the Alcalde of Almendralejo, province of Badajos, Spain. Tenders by Oct. 13.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Cumberland and Westmoreland Lunatic Asylum, Carlisle.—Tenders are required for plant. Copies of tender may be inspected at the office of the Consulting Engineer, Electricity Works,

Digitized by Google

Northallerton, Yorks. Tenders to the Clerk to the Committee of Visitors by Nov. 1.

Rochdale.—The Tramways Committee require tenders for the wiring of car depôt. Applications, with £1. 1s. deposit, to Mr. C. C. Atchison, borough and tramways electrical engineer, Rochdale. Extra copies 5s. each. Tenders, endorsed "Car Depôt Wiring," to be addressed to the Town Clerk, Town Hall, Rochdale.

Sunderland.—The Corporation invite tenders for the supply of two 300-kw. three-phase generators, 5,500 volts, to be coupled to existing Belliss engines, and two 300-kw. synchronous three-phase motors, 5,000 volts, to be coupled to existing multipolar Silvertown dynamos. Tenders by 28th inst. See advertisement.

Rochdale.—The Corporation invite tenders for the supply, delivery, and erection at the electricity works, Rochdale, Lancs., of three ejector condensers, three electrically-driven circulating pumps, and the necessary extensions of the steam, exhaust, and water pipes, valves, and accessories. Tenders by Oct. 10. See advertisement.

Philippopolis (Roumelia).—The Municipality requires tenders for a concession to construct and work electric lighting and tramways for 50 years. A guarantee of £6,000 is required. Tenders by Oct. 15. On the next day a second adjudication will take place in case there is an offer of £5 per cent. less per kilowatt-hour than the minimum.

Craivo (Roumania). — The *Moniteur des Intérêts Matériels* (Brussels) announces that the adjudication will take place at 4 p.m. on Oct. 25 (Nov. 7) at the Mayoralty of Craïova, of the concession for construction and working of a line of tramways (mechanical traction) in the town of Craïova. The duration of the concession is fixed at 50 years. A provisional deposit of £200 is required.

Antwerp.—The Municipality of Ghent invite tenders for the construction of 10 electric cranes at that port in accordance with the specification, a copy of which may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C. An initial deposit of 2,000fr. (£80) is required to qualify each tender, and for the tender accepted a further deposit of 18,000fr. (£720). Tenders, in registered envelopes, addressed "Au Collège Echevinal de la Ville de Gand," must be posted not later than Oct. 17. The adjudication will take place on Oct. 19.

La Rochelle (France).—The Chamber of Commerce will shortly issue tenders for a crane with a lifting power for 30 tons. The beam, or the part which projects over the water or vessel alongside, should be long enough to unload from a point about 26ft. 6in. from the edge of the quay. The height of the distal end above the quay should be 15m. (49·21ft.); the vertical distance between the edge of the quay and that part of the crane directly over it, 8m. (26·4ft.). A locomobile is preferred, but should the conditions be unfavourable for installing such a machine, then a fixed crane would be adopted.

RESULTS OF TENDERS.

Hull.—The Baths Committee have accepted the tender of the Lancashire Electric Engineering Company, at £180, for electric light fittings at the Beverley-road baths.

Birmingham.—Messrs. T. Sugden, Limited, 180, Fleet-street, London, have secured an order to instal 14 of their superheaters in connection with the Lancashire boilers for the Corporation electricity works.

Mortlake.—The Urban District Council have accepted the tender of G. and H. Turner, 11, High-street, Harlesden, N.W., at £105. 15s., for wiring their isolation hospital, South Worple-way, Mortlake, for electric lighting.

Hammersmith.—The Guardians have accepted the tender of the Private Wire and Telephone Installation Company, Limited, 5, Palmer-street, Westminster, S.W., for a complete installation of telephones, fire alarms, and electric bells in the new workhouse and infirmary at Wormwood Scrubbs.

Aberdeen.—The Tramways Committee have received tenders for the supply and delivery of 20 top-deck car-covers from R. and. J. Shinnie, Union-row, Aberdeen (accepted); Brush Electrical Company, Limited, Loughborough; Hurst, Nelson, and Co., Motherwell; Milnes, Voss, and Co., Birkenhead.

Broxburn.—The following tenders have been accepted for the erection of the power station for the electric installation: P. Orr, jun., at £272. 16s. 6d., brick and concrete work; M. M'Gavin, at £125. 17s. 4½d., joiner work; G. Paris, at £52. 15s. 10d., slater work; W. J. Nicol, at £26. 7s. 4d., plumber work.

Wrexham.—The Town Council have received the following tenders for Section 1 of the proposed extensions, including the distributing cable, disconnecting boxes, service boxes, and wood troughing: Callender Company, £2,269. 13s. 4d.; St. Helens Cable Company, £2,138. 17s. (recommended for acceptance).

Scottish Central Supply Company.—Messrs. Bruce Peebles and Co., 25, Victoria-street, S.W., report acceptance of the following tender: complete engine-house equipment for the above, including one 1,200-i.h.p. set, two 600-i.h.p. sets, two 150-kw. sets, exciters, switch-gear, etc.; electrical plant, first installation, £15,500.

West Ham.—The Town Council have received the following tenders for the supply, delivery, and erection of all poles, fittings, wires, and pillars required for the electrical equipment of approximately 3 miles 3 furlongs of tramway track:

R. W. Blackwell and Co., 59, City-road, E.C. (accepted)	£3,851	0	4
Brush Electrical Engineering Company, Belvedere-road, S.E.	4,141	2	9
British Insulated and Helsby Cables, Prescot, Lancs.	4,502	2	6
British Electric Equipment Company, 11, Queen Victoria-street, E.C.	4,567	13	6
Dick, Kerr, and Co., Abchurch-yard, Cannon-street, E.C.	4,579	2	2
Borough Electrical Engineer, West Ham	4,887	5	2
Macartney, McElroy, and Co., 53, Victoria-street, S.W.	4,911	10	8

London County Council.—The Bridges Committee have received the following tenders for renewing the electric light installation on the Woolwich ferryboats "Duncan" and "Gordon":

Scott and Mountain, Limited, Newcastle	£718	0	0
Newtons, Limited, Taunton	807	12	0
	815	12	0
Siemens Bros and Co., London*	812	0	0
Johnson and Phillips, Charlton	890	0	0
General Electric Company, Limited, London	1,068	0	0
Electric Construction Company, Limited, Wolverhampton	921	0	0
	969	0	0
	1,085	10	0
	1,131	10	0
	1,221	0	0
	1,265	0	0
Belliss and Morcom, Limited, Birmingham	1,282	0	0
	1,306	0	0

* Recommended for acceptance.

BUSINESS NOTES.

TRACTION.

Halifax.—The Council have rejected a proposition to institute ½d. fares for children.

Cheltenham.—The work of extending the light railway was commenced last week, and excellent progress is being made.

Nantes.—A decree authorising the tramways company to extend their system has just been signed by the President of the Republic.

Rochdale.—The Oldham-road and Milnrow-road routes have been completed. The Manchester-road section is also approaching completion.

Colchester.—The Council are to make application for a loan of £50,000, being part of the loan of £61,164 authorised for tramways purposes.

Leeds.—The Corporation have decided to apply for a provisional order authorising the construction of two further lines in the direction of Pudsey.

Handsworth.—Following on our last week's note stating the terms agreed upon between the Council and the company, the former have now executed the lease.

Birkenhead.—Sunday running has been discontinued on the Claughton-road and the docks routes, the Corporation finding the receipts to be inadequate.

Dover.—The *plébiscite* on the question of Sunday running has resulted in a negative vote, the numbers being: against, 3,021; for, 2,887—majority against, 134.

Norwich Electric Tramways Co.—For the year ended June 30 the directors recommend a dividend of 3 per cent., leaving £609 to be carried forward after placing £1,012 to reserve.

New York Underground Railway.—It is reported that on an experimental trip on Monday a train covered the seven miles' trip in 10 minutes 45 seconds. The air was clear and no dampness was apparent.

Beckenham.—The Urban District Council have approved the draft of an agreement with reference to the £20,000 debentures to be given by the British Electric Traction Company as security for the performance of the tramway contract.

Goods Traffic.—It is reported that a concern, entitled "The South Wales Transport Company, Limited," is to be promoted for the purpose of providing a system of electric cars for haulage purposes, and electric 'buses to tap those parts of Swansea and district not served by the tramcars.

Perth.—Perhaps the Corporation will now turn their attention seriously to electrification. Notwithstanding the favourable accounts given two or three weeks ago, the petrol cars have been found not to give unmixed satisfaction, and it is expected that this idea will now be abandoned.

Brighton.—At the meeting of the Steyning East Rural District Council the clerk was instructed to obtain counsel's opinion as to the proper steps to be taken against the Brighton Corporation for the alleged trespass in laying the tramways not in accordance with their statutory powers.

Anglo-Argentine Tramways Co.—The scheme of arrangement with the City of Buenos Ayres Tramways Company (in liquidation) having now been sanctioned by the Court, the liquidators have decided to make forthwith the first cash distribution under the scheme of 4s., in lieu of the usual dividend to June 30 last.

Leicester.—The Corporation have sanctioned the expenditure of £60 000 upon additional plant and cars. The Chairman of the Tramways Committee, in proposing this step, remarked that there was ample room for the new cars, which will bring the total up to over 120. A new design of top cover is in contemplation.

Pontypridd.—After appointing an arbitrator, it appears that the District Council and the British Electric Traction Company have agreed upon terms, the company having decided to accept £5,500. Application is to be made to the Board of Trade for borrowing powers in order to convert the line to electric traction. The Council will work the system itself.

Chesterfield.—In another column will be found an account of the legal proceedings instituted by the Newbold Urban District Council in connection with the laying of the electric tramway. At a subsequent meeting of the Urban District Council a more conciliatory tone prevailed, reference being made to the advantages which Newbold may expect from the new service.

Digitized by Google

Accrington.—In framing their scheme of tramway extensions, the Corporation encountered some little difficulty with the Oswaldtwistle District Council, which required somewhat onerous terms, and there seemed a likelihood of this section being omitted from the Bill to be promoted by the Corporation next session. After exchanging views, however, the difficulty has been practically settled, and at its next meeting the Corporation will decide upon the details of the extension scheme.

Dunfermline.—At a meeting on Wednesday of the Dunfermline District Committee of the Fife County Council a letter was submitted on behalf of the promoters of the Dunfermline and District Tramways Company for approval to a provisional order for tramways from Dunfermline to Lochgelly and from Dunfermline to Inverkeithing. In the first-mentioned case the line would pass through the populous districts of Lumphinnans, Cowdenbeath, and Crossgates. The matter was referred to committee.

South Shields.—The tramways question still awaits settlement. At the meeting of the Town Council on Monday a resolution in favour of municipalisation was moved, and several members expressed themselves in accord with the scheme, as the terms offered by the companies did not promise to yield much profit to the municipality. The Mayor approved of construction by the Corporation, but was not prepared to support municipal management. Finally, the matter was adjourned until next week's meeting.

Leith.—The sub-committee which recently inspected various electrical systems of tramway tramways in England and Scotland have issued their report. The deputation state that they have come to the conclusion that, financially and mechanically, the overhead electric system is the most suitable for Leith. The deputation prefer a neat centre pole with arms for the wider streets and brackets in other parts, and advocate cars like those in use at Liverpool and Leicester, some of them to be provided with top covers.

Aberdeen.—The convener of the Tramways Committee has compiled some interesting figures in regard to the interchange of traffic between the Corporation and the Suburban trams. During one week it was ascertained that on the Donside section 4,153 persons came on to the Corporation cars from the Suburban, and that 4,255 persons went to the Suburban cars from the Corporation cars. On the Deeside section 2,782 passengers came off the Suburban cars and boarded the Corporation cars, while 2,764 left the Corporation cars and went on to the Suburban.

Bettws-y-Coed.—The Urban District Council have confirmed the letter drafted by a committee asking the Board of Trade to require the line to be taken past the Swallow Falls through a tunnel, to avoid spoiling the wooded cliff opposite the falls. Instead of the proposed bridge over the road at Pont-y-Pair, Bettws-y-Coed, the Council ask that there shall be a level crossing, so as not to spoil the fine view. As to Sunday traffic, the Council are anxious that the peaceful state of the district on Sundays should remain undisturbed, and would like the Board of Trade to stipulate that no trains be run on Sundays except for mail purposes.

Proposed New Tramway.—It is reported that application will be made next session on behalf of one of the principal electric traction companies for a Bill to authorise the construction of a continuous line of electric tramways along the coast from Ramsgate to Hastings, *vid* Dover, Folkestone, and Littlestone-on-Sea. The proposed undertaking, it is understood, forms part of a still larger project which will link up the tramway systems of Brighton, Worthing, and watering places still further westward with the existing electric light railways in the Isle of Thanet. Strenuous opposition is to be expected from the railway companies affected.

Bury.—At a special meeting of the General Purposes Committee on Monday, the Tramway and Parliamentary Committees submitted a recommendation that a Bill be promoted in the next session of Parliament authorising the extension of the present Bury tramways to the borough boundary on the Jericho, Lime Field, and Bolton-road sections. The recommendation was approved, and referred to the Council meeting for adoption. The extension of the Bolton-road section will connect with the proposed extension of the Bolton system, and will give Bury direct tramway communication with Liverpool. The Tottington section has been completed.

Edinburgh.—The Lord Provost's Sub-Committee has considered the recent memorandum issued by the directors of the tramway company to the members of the Council on the rent to be paid for the undertaking. The memorandum asked practically for a remission of £50,000 of the capital sum on which interest is paid, on the ground that the company understood that the capital sum was not to exceed £1,300,000. The points in the memorandum were gone over seriatim, and it was stated the town clerk had pointed out the inconsistency of the position taken up by the tramway directors, and the inaccuracies the memorandum contained. It was agreed that the town clerk should prepare an answer to the several points raised in the memorandum, and present it to a future meeting of the committee.

Birmingham.—The Works Sub-Committee received a deputation from the local Trades Council, who urged that local labour should be employed in the construction of the tramways and that the work should not be let out to contractors. The Chairman expressed sympathy with the object which the Trades Council had in view, but said it was impossible for the committee to give a definite promise to carry out the suggestions which the deputation had laid before the sub-committee. Every case must be considered by the committee on its merits, having regard to the special circumstances, and the interests of the ratepayers as a whole. The matter would, however, receive the consideration of the sub-committee, and they would use their influence as far as possible to secure the employment of local labour.

Remarkable Construction Performance.—Messrs. Dick, Kerr, and Co. have excelled themselves in the construction of the permanent way for the Birmingham Corporation tramways. It was an essential condition of the contract that the work should be completed in a short space of time, besides which the contractors had to preserve a portion of the road intact, not only for ordinary traffic, but to allow of the steam cars continuing their service. Notwithstanding these difficulties, Messrs. Dick, Kerr, and Co. have completed the work, comprising 9,820 lineal yards single track and 11 junctions with 20,000 square yards of new paving outside the tramways, in 12 weeks, during a part of which the work was proceeded with at the rate of over 2,300 yards per week—surely a record, considering the conditions.

North-Eastern Railway Company.—A trial was made on Sunday with the new electric locomotive which will ultimately be used to haul goods trains from the Quayside at Newcastle to the higher level. A train was made up of 18 10-ton trucks of coal (averaging 16 tons 5cwt.) and two vans (10 tons each), dragging an ordinary locomotive in case of accident or breakdown, so that, exclusive of the electric locomotive, the deadweight was more than 390 tons. The new engine is available for use either on the Quayside, which has the overhead system, or on the upper track and live rail. The trial was very successful. Only one stop was made, at Tynemouth, to cool down the friction surfaces. The experiments were watched by representatives of the Thomson-Houston Company, as well as by North-Eastern Railway officials from the locomotive department.

Gloucester.—The Corporation have decided, by way of experiment, that the fares on workmen's cars be reduced to ½d. for journeys between the Cross and any part of the city system. The general manager has been instructed to consider the question of providing a parcels service, and to prepare a scheme for the consideration of the committee. The following details have been announced concerning the working of the tramways: The receipts for the 20 weeks' running, from the time the cars commenced to run up to Tuesday, totalled £7,222. 3s. 3d., the average per car mile being 8·12d. The passengers carried were 1,846,000, of whom 750,000 were ½d. fares. The passengers at 1d. were 706,000, and 294,000 paid higher fares. There had been issued 25,000 workpeople tickets and 10,749 school tickets, with 8,640 specials for school excursions, etc.

Durham Light Railway.—The Neville's Cross Parish Council have instructed the clerk to address the following communication to the Board of Trade: "I am directed by the Parish Council for the parish of Neville's Cross to inform you they have received notice that the British Electric Company intend to make application to prolong the time for the completion of the railways under the Durham and District Light Railways Order, 1901, until Oct. 4, 1905. The Parish Council also directs me to inform you they object to the application on the ground that nothing whatever has been done within the parish of Neville's Cross to carry the order into effect, although the order has been in force for nearly three years. In the event of the company giving a sufficient guarantee for the completion of the work before October, 1905, the Parish Council will favourably consider the desirability of withdrawing their objections."

Bury, Rochdale, and Oldham.—It will be remembered that the arbitrator awarded the company £159,075, to which has to be added £3 600 agreed upon for street improvements. Mr. More has now allocated the purchase money between the different authorities on the basis of car mileage in regard to plant, rolling-stock, buildings, etc., while the sum for permanent way has been divided according to the value of the respective sections. The £162 675 is thus apportioned: Rochdale and Wardle, £70,390. 6s.; Littleborough, £7,033. 15s. 9d.; Royton. £15,544. 2s.; Heywood, £20,436. 16s. 3d.; Bury, £38,441. 19s.; Tottington, £4,191. 13s. 6d.; Unsworth, £3,016. 15.; and Whitefield, £3 620. 1s. 3d. The taxed costs of the arbitration will probably be allocated on the basis of mileage. The respective authorities will be credited *pro rata* with the proceeds of such of the old stock as is not now required when the same has been realised.

Derby.—The manager has been instructed to allow the use of special electric cars, when it can conveniently be arranged, upon payment of 5s. and the full fare for a minimum of 40 passengers. A petition having been received, signed by numerous ratepayers, asking for the extension of the tramways route to the Market-place, the committee have decided to inform the petitioners that the suggested extension cannot be made until the next scheme is taken in hand. The committee have decided to discontinue the running of cars from the Midland Railway Station to Alvaston. The Tramways Committee have had under consideration the question of establishing an insurance fund against third-party risks, and they have decided, subject to the approval of the Council, to place the sum of £1,000 from the proceeds of the accumulated revenue of the tramways to the credit of a reserve fund, and also to contribute to such fund £10 in respect of each car per annum. The penalty incurred by J. G. White and Co., Limited, contractors for the construction of the electric tramways by reason of the works not having been completed within the prescribed time is £28,032. The Finance Committee have informed the Tramways Committee that no further certificates to J. G. White and Co., Limited, will be honoured until accounts between the contractor and the Corporation have been adjusted.

Newcastle.—At the meeting of the Corporation last Friday, Alderman Ellis, chairman of the Tramways Committee, in presenting for confirmation the estimates for the year ending March next, of which we gave particulars last week, remarked that the gross profit of £67,275 only left an estimated balance of £2,541 to be set aside as the nucleus of a depreciation fund. He attributed this result to excessive expenditure and over-capitalisation In regard to the former the committee had effected economies in the staff, and proposed to obtain a further saving by the same means. He also considered it unfair that the undertaking should have to pay £3,105 for income tax. Two or three councillors expressed confidence that the work of revising the methods of conducting the undertaking would result in reduced traffic expenses, as at present the car mileage was excessive. A somewhat

Digitized by Google

lengthy discussion ensued on the depreciation question. Eventually the estimates were adopted on the understanding that this matter shall receive further consideration at a future meeting. The new line which has been laid over the railway bridge in New Bridge-street has been joined to the old one which runs between Pleasant-row and New Bridge-street Station. Cars are running on the new section towards the city, and when the line to Heaton has been connected up there will be a direct route from Pleasant-row to the city, obviating one of the most dangerous routes on the system.

Belfast.—The minutes of the Tramway Committee presented to the Corporation at its meeting on Monday stated that the city surveyor (Mr. Cutler), electrical engineer (Mr. M'Cowen), and general manager (Mr. Nance) had issued a joint report, stating that they proposed to issue separate specifications for track work, overhead electrical equipment, underground feeder cables, buildings for the extension of the generating system, engine-house plant, boiler-house plant, single-truck double-decked cars, and to issue a form of tender containing each of the heads above enumerated. A deputation from the Belfast branch of the United Kingdom Society of Coachmakers had been received by the committee, and were informed that 220 cars would be required, and it was intended that 50 of these should be built in Belfast, and that after the original number had been supplied any additional cars or repairs would be provided for locally. The city surveyor submitted to the committee draft specification for the permanent way, and was instructed to provide for work being commenced within two months of the tender. The penalty for non-completion within the time contracted for to be £1,000 per week after the expiration of the said period. After a lengthy discussion the minutes were adopted. Previous to the sitting the Corporation received deputations from 11 industrial organisations, whose delegates urged that the conversion of the tramways and the building of the cars should be done by local labour under the control and supervision of the Corporation.

Aston.—The Public Works Committee presented to the Town Council on Wednesday a report relating to the purchase from the City of Birmingham Tramways Company of tramways belonging to the company in the borough. The purchase is of the tramways in High-street, Birchfield-road, Witton-road, Lozells-road, and Wheeler-street, together with the land and buildings in the Witton-road, and the rolling-stock required to work these lines; also the prospective profits which the company would have been entitled to had they worked the lines for their own benefit from June 1, 1904, to Dec. 31, 1905, and to June, 1911, in the case of the Wheeler-street line. The price was to be settled by arbitration, and the committee reported the award of Mr. Robert Green as £26,045. The Council has to pay interest at the rate of 4 per cent. per annum on this sum from Jan. 1, 1904, the Council taking the profits from the working of the undertaking as from that date. The arbitrator's fees and charges, to be paid by the Council, amount to £361. 18s. The committee also reported in regard to the Aston Station railway bridge. As a result of a lengthy correspondence and several interviews between the town clerk, the consulting engineer (Mr. Robert Green), and the chief officials of the London and North-Western Railway Company, terms have been provisionally arranged for the rebuilding of that part of the railway bridge extending over the Lichfield-road. The railway company has intimated its willingness to reconstruct the bridge and to make such alterations thereto as are desirable at an estimated cost of £5,760, the work to be done under the direction of the company's engineer at the expense of the Council. Just as we go to press we learn that the Council have confirmed this arrangement. It is not intended to commence the reconstruction of the above-mentioned lines until the new year. The chairman of the Tramways Committee proposes to confer with the Birmingham Corporation, as the latter apparently object to continuing their service beyond Aston Cross, with the result that communication between the city and Witton is greatly restricted.

London County Council.—At Tuesday's meeting of the Council a resolution was moved that, in order to facilitate the traffic requirements of South London and the public generally, the Highways Committee be instructed to bring up in time for the next parliamentary session a scheme for joining the tramway termini at Blackfriars Bridge and Westminster Bridge by means of a tramway constructed across the two bridges and along the Victoria-embankment, in order to provide a continuous circular route by which the blocks in Blackfriars-road and Westminster Bridge-road might be obviated. This found a ready seconder, but the Chairman of the Highways Committee pointed out that a difficulty would arise from the fact that Blackfriars Bridge was the property of the City Corporation, which would have to be consulted. He agreed that no improvement was more important than that proposed, but thought that a mere reference to the Highways Committee instead of an instruction would better meet the circumstances of the case. This suggestion was accepted, and the resolution, amended accordingly, agreed to. The report of the Highways Committee contained recommendations that a capital vote of £1,000 be made for a site on which to erect a sub-station in connection with the Battersea and Wandsworth lines; that Messrs. H. Lovatt, Limited be accorded permission to sublet the work of plumbing, painting, and glazing in connection with the Greenwich generating station; and that an agreement be sealed for the acquisition of a site near Old-street for a sub-station. The committee also reported that they were considering the best course to adopt in regard to the London, Camberwell, and Dulwich tramways, which has now been acquired by the Council, and that the Board of Trade has appointed Major Cardew, R.E., as arbitrator in reference to the acquisition of the Woolwich and South-East London Tramway Company's undertaking. In a report just issued by the Stepney borough engineer, Mr. W. M. Jameson, reference is made to the forthcoming electrification of the tramways, and to the proposal of the London County Council to use the overhead system on some of the East-end routes. Mr. James deprecates the overhead system on æsthetic principles, besides which he alludes to danger from falling wires, and the likelihood of electrolysis resulting from the return rail. The report hails the advent of electric trams, as their increased speed may be expected to appreciably relieve the congestion, but Mr. Jameson suggests that it would be advisable to remove the terminus 124 yards eastward from the present point in Aldgate.

LIGHTING AND GENERAL.

Bray.—The engineer is to report fully and submit a scheme for arc lighting.

Birkenhead.—The Local Government Board have sanctioned a loan of £6,500 for electrical works.

Bournemouth.—The Town Council on Wednesday decided to apply for a municipal telephone license.

Havant.—The laying of underground wires by the Municipal Telephone Committee has been sanctioned.

Southampton.—Provision has been made out of the profits of the past year for the repair of the older mains.

Broxburn.—The opening of the streets for the laying of the cables for the electric lighting of the district was commenced on the 29th ult.

Walthamstow.—An enquiry has been held into the application of the Council for £46,000 for further extension of the electric lighting station.

Stepney.—The Borough Council have decided to apply to the London County Council for a further loan of £220,000 for supply purposes.

Leicester.—The profit made by the Corporation during the half-year ending in June last on the water and electric lighting undertaking was £11,000.

Litherland.—The ratepayers' association have passed a resolution suggesting that the Urban District Council of Litherland apply for an electric lighting provisional order.

Lowestoft.—An enquiry has been held into the application of the Corporation for sanction to borrow £3,600 for purchase of property in connection with the light undertaking.

Removal.—Messrs. John Davis and Son, Limited, Derby, have removed their London offices from 26, Victoria-street, Westminster, S.W., to Camomile-street-chambers, London, E.C.

Cheltenham.—The monthly report of the electrical engineer shows that there are 778 customers, with the equivalent of about 50,660 8-c.p. lamps connected to the private supply mains.

Paris.—The *Journal Officiel* publishes a decree authorising the Algiers Chamber of Commerce to borrow 16,000fr. for the construction of a telephone line between Boghari and the Algiers system.

Bishop's Stortford.—After discussion, a resolution to the effect that an application be made for a provisional order, the Urban District Council last week adjourned the subject for further information.

Gloucester.—An agreement between the Electrical Power Storage Company, Limited, and the Corporation for the maintenance of the battery for 10 years has been approved. Some of the new arc lamps are now in use.

Tottenham.—The Council are inviting offers for the supply of electricity in bulk, or otherwise, under the Council's electricity order, the proposals to be received not later than Friday, Oct. 21. Particulars appear in another column.

Devonport.—A further report is to be prepared in reference to the provision of additional plant in the Stonehouse power station. The committee do not recommend the turbine. The estimated cost for the proposed additions is about £10,000.

Oulton Broad.—The Urban District Council have discussed a proposal to apply for a provisional order for electric lighting. Finally, the matter was adjourned pending an interview of a deputation of the Council with Messrs. Barber and Croft.

Hammersmith.—The premises of nine additional consumers, representing a maximum of 577 8-c.p. lamps, have been connected to the mains; seven consumers have been disconnected. The present number of consumers taking current from the mains is 1,502.

Wednesbury.—Sanction has been received to a loan of £465 for the purposes of lighting with electricity the town hall, municipal offices, public library, art gallery, and public baths. The extension of the electrical main in the King's-hill district is receiving attention.

Dublin.—The Corporation on Monday adopted a report on the supply of electrical energy to the old electric lighting area by Mr. Ruddle, city electrical engineer, recommending the laying of new mains in St. Stephen's-green, Westmoreland-street, and Kildare-street, at a cost of about £1,300.

Leigh.—At a recent special meeting of the Town Council, it was stated that extensions at the electricity works were so urgently required that it was proposed to go on with the work before they got the sanction of the Local Government Board to borrow the money. The extensions were approved.

Woolwich.—The electrical engineer's scheme for the supply of electricity to Shooter's Hill and Eltham has been referred back for further consideration. Section A, dealing with the Shooter's Hill district, was estimated to cost £13,008; and Section B, dealing with the further extension to Eltham, would cost £12,585.

Colchester.—The last report of the borough electrical engineer contains the following figures: output of electricity in units during August, 1904, 65,444 (1903, 19,093; 1902, 12,043); number of consumers at end of August, 529 (370; 292); total number of 8-c.p. lamps connected, 26,728 (23,206; 17,462).

Village Post Offices.—The telegraph at various village post offices in Northamptonshire has been abolished, and the telephone has been installed in its place. It is understood that the telephones at village

Digitized by Google

post offices will be less expensive than ordinary A.B.C. telegraphic apparatus, less liable to accidents, and require less technical knowledge on the part of the village operator.

Brighton.—The Town Council propose to extend the basement flooring of the power station at Southwick so as to cover the whole of the engine-room area, instead of part only, as provided for under the contract with the British Westinghouse Company; also to construct a switchboard gallery at the North-road converter house. It is proposed that the work be done by the British Westinghouse Company for £5,285 and £820 respectively.

London County Council.—On Tuesday tenders were received, and referred to committees, for the erection, etc., of condenser water-pipes, etc., at the Greenwich tramways generating station; for the erection, etc., of three electric car traversers at the London County Council tramways depôts; for the erection, etc., of pumping plant at the Greenwich tramways generating station. A number of notices of intention to lay mains was agreed to.

Barrow.—The accounts of the electricity department for the year ended March 31, 1904, show a total capital expenditure of £78,575. £11,202 being expended during the past year, principally for additional plant and machinery for the purpose of supplying current to the trams. Loans have been borrowed to the extent of £73,575, and £6,078 has been repaid. The deficiency in this department was reduced last year by £478, and the loss on previous working of the undertaking now stands at £1,181.

Wood Green.—At the last District Council meeting the electricity scheme and the Local Government Board's refusal to sanction the borrowing of £43,570 were considered, and the following resolution was passed: "That this Council regrets the decision of the Local Government Board, but still adheres to the repeatedly expressed policy of obtaining a municipal supply of electricity according to the powers granted it by Parliament; and instructs the Electricity Committee to submit a report for consideration."

Underground Telegraph to the North.—The *Carlisle Journal* says: "On Wednesday, Sept. 28, another stage in the work of providing the public of the North of England and Scotland with a telegraphic system which will not be affected by storms was completed. On that evening the workmen drew the cable across Eamont Bridge, thus bringing the work into Cumberland, and in a few days Penrith will be reached. Should the weather continue favourable, it is hoped that the cable may be laid to Carlisle by the end of the year, though this scarcely appears likely to be accomplished."

Handsworth.—In reference to the announcement in the *London Gazette* that the Board of Trade had revoked the Handsworth Electric Lighting Order, 1901, the *Birmingham Post* says that upon enquiry at the office of the clerk to the Handsworth District Council Mr. Ernest Ward, the assistant clerk, stated that the notice in the *London Gazette* did not apply to their district, but must refer to the village of Handsworth, near Sheffield. So far as the neighbouring district of Handsworth is concerned, the electric supply scheme is so forward that the cables have been laid, and the erection of a generating station in Piers-road is in progress.

Loughborough.—The Town Council hope to start in the course of a week or two to supply electric current in the town. The boiler-house at the works contains two dry-back boilers, built by Danks and Co., of Dudley, two boiler steam-feed pumps, a storage tank of 15,000 gallons capacity, and an economizer of 200 tubes. In the engine-room are two Brush turbines, connected direct to two generators of 250 kw. capacity, and a Siemens balancer-booster. The battery-room contains 260 cells, giving 50 amperes for 10 hours' current. The buildings have been erected by Mr. A. Faulks from plans prepared by Mr. A. E. King.

Stoke-upon-Trent.—The Town Council have passed a vote of thanks to the North Staffordshire Railway Company for the kind services of Mr. Rock in connection with the testing of the mains. The Princess-road main is to be extended from Quarry-road to opposite the Mount. The works being almost completed, the Mayoress will be requested to perform the opening ceremony at the end of the month. There are now 54 premises in the borough wired up for immediate supply, and a considerable number of orders have come in since then. The committee are very gratified with the promising prospect for the use of electric energy for motive purposes in the borough.

Retford.—Mr. A. B. Mountain, in his report on the supply of electric light for the borough, estimates that a steam plant would cost £14,000, and a gas plant £10,000, to supply 300 houses. After the first three years there would be a surplus balance of £410. He proposed to put down a small plant of £5,070 first, which would leave a balance of £177 to be provided for the first few years, but this would gradually be worked out. He strongly urged the Corporation to undertake the work themselves, as they could supply it much cheaper than any outsider, and if they did not do so, someone else would take it up, and the town would afterwards have to buy them out at a very much higher figure.

Beckenham.—At the last Urban District Council meeting it was reported that the claim of the Crystal Palace District Electric Lighting Company, amounting to £7,897. 12s., for the transfer of so much of their undertaking as is within the district of Beckenham, has been received. A draft agreement with the Penge Urban District Council as to the laying of the necessary connecting cable is being examined. The British Insulated and Helsby Cables, Limited, have agreed to pay one-fifth of the expense of appealing against the assessment of the electric lighting works. Tenders are to be invited for the erection of the baths in connection with the dust destructor and electric lighting works, and application is to be made for sanction to a loan of £210. New cables are to be laid at a cost of £64, £35, and £110.

Worthing.—With reference to the proposal of the Post Office to erect telephone posts in various roads, the Post Office authorities have pointed out that the proposed new telephone line was incidental to the development of telephonic communication within the borough, and that its erection was in the interests of the ratepayers. The Postmaster-General considers the cost of underground wires prohibitive, and is not disposed to have recourse to expensive underground work when a suitable route for the line of posts is accessible in the public streets, of which he has the right to avail himself under the Telegraphs Acts. One of these roads accommodates standards for electric arc lamps already. The Highways Committee being still of opinion that it is undesirable to consent to the erection of the posts in the locality named, have again recommended the Council to withhold consent. At the meeting of the Council on Monday the recommendation was sent back for reconsideration.

York.—The report of the electrical engineer (Mr. C. A. Midgley) on the fourth year's working shows an increased sale of current of 114,542 units, the total being 776,542 units, representing an increase of 20 per cent. on last year. The number of motors connected to the system is now 110, representing 530 h.p., while the number of units sold under this section has increased to 184,472 units, showing an advance over last year of 54,472 units, equal to an increase of 42 per cent. The number of consumers has increased from 386 to 470, being a growth of 22 per cent. The maximum load on the station has increased from 550 kw. to 651 kw., the capacity of the plant being 720 kw. The total capacity of the plant now the extensions are completed is equivalent to 54,000 8-c.p. lamps burning at one time. This will admit of a total lamp connection with sufficient reserve of plant of 62,000 8-c.p. lamps being connected, and to date there are connected to the mains a total of 55,200 8-c.p., and 1,500 8-c.p. awaiting connection. Notwithstanding an increase in sales, the expenditure has been less than the previous year by £225, and the net balance on the year of £350 clears the department of all liabilities.

London Gazette.—An adjudication order has been made out in the estate of Henry Coles, electrical engineer, 10, York-street, Swansea. A general meeting of the Renewable Electric Lamp Company, Limited, will be held at 12, St. John's-lane, Liverpool, at 12 o'clock noon on Nov. 5, 1904, to receive the liquidator's accounts, showing the manner in which the winding up has been conducted and the property of the company disposed of. A general meeting of the Electric Extension Company, Limited, will be held at 12, St. John's-lane, Liverpool, on Nov. 5, 1904, at 11 a.m., to receive the liquidator's accounts, showing the manner in which the winding-up has been conducted and the property of the company disposed of. The London Electrical Syndicate, Limited, has been wound up voluntarily, and George Pearson, 196, Abbott-road, Poplar, appointed liquidator. A general meeting of the members of the Clayton Engineering and Electrical Construction Company, Limited, will be held at the Grand Hotel, Manchester, on Nov. 4 at 12 o'clock noon, to receive the liquidator's report showing how the winding-up of the company has been conducted and its property disposed of. The partnership between Charles Herbert Offord, Frank Clemens Wilson, and Archibald Carlyle Barfield, carrying on business as electrical engineers at Woodcock-street, Birmingham, under the style of "Offord, Wilson, and Barfield," has been dissolved by mutual consent.

Fulham.—In February the Council passed the following resolution: "That the offer of the directors of the Granville Theatre of Varieties to take the whole of their electric current from the Council's mains for a term of seven years at 3d. per unit, and to guarantee during that period a minimum consumption equivalent to £450 per annum, be accepted, subject to their entering into a satisfactory agreement embodying this arrangement and safeguarding the Council's interests." It is now proposed that the resolution be rescinded so far as regards the guaranteed minimum consumption of current equivalent to £450 per annum, and that a guaranteed minimum consumption of current equivalent to £430 per annum be accepted by the Council, and the agreement with the directors of the Granville Theatre of Varieties completed accordingly. The borough electrical engineer has submitted the following statistics: Refuse destroyed—previously reported since April 1, 1904, 8,603 loads, 13,220 tons; from Sept. 8 to 22, 1904, 716 loads, 1,103 tons—total, 9,319 loads, 14,323 tons. Trade refuse—previously reported since April 1, 1904, 302 loads, 292 tons; from Sept. 8 to 22, 1904, 28 loads, 28 tons—total, 330 loads, 320 tons. Clinker disposed of—previously reported since April 1, 1904, 3,416 tons; from Sept. 8 to 22, 1904, 211 tons—total, 3,627 tons. Connections—previously reported, 1,260 (59,893 8-c.p.); from Sept. 8 to 22, 1904, 18 (744 8 c.p.)—total, 1,278 (60,637 8-c.p.).

Wrexham.—The electrical engineer's last report on connections and supply was as follows: August, 1904—used for tramways, 11,995 units; August, 1903—14,157 units. August, 1904—used for lighting, etc., 18,167 units; August, 1903—17,646 units. August, 1904—power (private), 835 units. Total consumption: August, 1904, 30,997 units; August, 1903, 31,803 units. New consumers connected, one; 8 c.p. equivalent of additions to connections, 84; total number of consumers, 139; against 132 in August, 1903. The Wrexham and District Electric Tramways Company require the current to be left on the lines all night during the winter months for the lighting of the depôt, the arrangement to commence Nov. 1 next, and consequently the electrical engineer has been authorised to order the special meter required for the purpose of correctly registering the quantity of electricity used at the higher rate of charge under the agreement with the tramway company. Tenders for the supply of distributing cable, disconnecting boxes, service boxes, wood troughing, complete fittings for converting gas standards and brackets to incandescent electric lighting, and enclosed arc lamps complete, have been referred to a sub-committee, to consist of the Chairman, the Mayor, Councillors Francis, Taylor, and Williams, with a view to recommendations for acceptance being made to the next meeting of the Council. A canvasser is to be appointed. The borough treasurer's statement relating to contracts in connection with the electricity department and alterations to destructor, shows that the total

Digitized by Google

amount of the contracts in connection with the department, including destructor, buildings, boilers, engines, dynamos, cables, lamps, switchboard, battery, crane, new chimney, and additions and alterations to many of the same, was £27,204; there were also extras amounting to £2,025, making the total £28,973.

Govan.—In a recent special report Mr. T. C. Parsons says it would be as well to reckon on using £20,000 for completing the present electricity extensions. With regard to the future requirements, he estimates that at the present rate of progress, in three years' time another 750-kw. steam dynamo with condensing plant and another boiler will require to be added to the station equipment. He adds that in the present year, 1904-5, an additional feeder will have to be laid to the foot of Helen-street. In the year 1905-6 a new feeder to the Plantation district will be required, and in the year 1906-7 a new feeder to the district round Albert-street. It was not very easy to estimate the amount required for purchasing motors to be let out on hire, as the department had only just started this branch of business, but in the two months in which they had been offering them applications for 51·5 h.p. and promises for eight more had been received, totalling about 180 h.p., and he thought it best therefore to allow £5,000 for this purpose. The estimated capital expenditure, therefore, up to the year 1906-7 is: Year 1904-5—completing present extensions, £28,753; new mains, £4,500; motors, £1,500; meters, £400—total, £35,153. Year 1905-6—mains, £5,000; motors, £2,000; meters, £400—total, £7,400. Year 1906-7—steam dynamo, £4,900; condensing plant, £750; boilers, £1,250; pipework, £150; sundries, £250; mains, £4,000; meters, £400; motors, £1,500—total, £13,200. Total for three years, £55,753. This brings up the total to the end of 1907 to £55,753, and as the department have £8,753 unborrowed although authorised, there remains £47,000 for which borrowing powers are required. To complete the present extensions only £20,000 is required. The engineer suggests that powers be sought to borrow the whole sum of £47,000. The income of the department for the year ending May 15, 1902, from all sources amounted to £4,915, the expenditure to £3,132, and the units sold were 409,397. For the year ending May 15, 1903, the income was £6,585, expenditure £4,264, units sold 597,910. For year ending May 15, 1904, the income was £9,291, expenditure £5,933, units sold 894,702. Mr. Parsons's estimate of income, expenditure, and units sold for the next three years is: for year ending May 15, 1905, income from all sources £11,912, expenditure £6,233, units sold 1,350,000; for year ending May 15, 1906, income from all sources £15,302, expenditure £7,544, units sold 1,926,000; for year ending May 15, 1907, income from all sources £18,542, expenditure £8,300, units sold 2,362,100. The capacity of the plant in the station at present is 1,100 kw., and, allowing a sufficient margin for stand-by, this plant would supply current to light 23,400 8-c.p. at one time. By the time the present extensions are completed the department will have plant capable of dealing with 46,400 8-c.p. alight at one time, and when the second 750-kw. machine is added this will deal with 69,800 8-c.p. alight at one time.

Islington.—The Council will to-night consider a report from the Lighting Committee, dated Aug. 26, 1904, as follows: "(1) Since the laying of the mains in the Canonbury and Hornsey Rise districts on the solid system, and the erection of feeder pillars for the purpose of regulating and controlling such mains, we have taken into consideration the general question of the electrical requirements of above-ground switchgear with a view to a minimum of public inconvenience, for while there is little objection to feeder pillars on broad footways in districts where the traffic is comparatively small, the multiplication of obstructions on the footways becomes a serious matter in the main arteries of the borough. In connection with the extension of mains being carried out this year in Stroud Green-road and Blackstock-road, and the mains already laid in Hornsey-road and Highbury New-park, it is necessary that, at the earliest possible date, switch and feeder pillars should be provided in Seven Sisters-road, Holloway-road, and Highbury New-park. Arc lamps have already been erected in these roads, but we consider for the reason stated above that it would be inadvisable to place separate feeder pillars in their immediate vicinity, and that the feeder pillars should be combined with, and form part of, arc lamp standards. Six ordinary high-tension feeder pillars are scheduled in the contract with the British Insulated and Helsby Cables, Limited, and as the manufacture of this class of apparatus is a speciality, and the cables have to be connected up by the cablemakers to the feeder pillars, we have asked the company to quote a price for a combined arc lamp column and feeder pillar in substitution for such of the ordinary feeder pillars as may not be required. They offer to supply and erect 12 combined feeder pillars and arc lamp columns, provided with high or low tension fittings in such numbers as may be required, at £77. 5s. each, making a total of £927, and we are of opinion the offer should be accepted. We propose to erect one of the pillars on the north-east side of Hornsey-road outside the London County Council school, and to substitute another for the present arc lamp column at the junction of Hornsey-road and Seven Sisters-road. The first proposal will necessitate an additional expenditure of £50 in respect of mains, connections, etc. We have forwarded these estimates, amounting in the aggregate to £977, to the Finance Committee, and subject to their being adopted and submitted by them we recommend (*a*) that the estimate of £977 submitted by the Finance Committee be approved, and that application be made to the London County Council for sanction to the borrowing of this amount; (*b*) that the offer of the British Insulated and Helsby Cables, Limited, to supply one dozen combined feeder pillars and arc lamp columns, provided with high or low tension fittings as may be required, including delivery and erection, in lieu of such of the feeder pillars scheduled in the mains contract for 1904-5, as the Lighting Committee may determine, be accepted, and that a contract under seal be entered into accordingly on the sanction to the loan being obtained; (*c*) that one of the combined pillars be erected on the north-east side of Hornsey-road in front of the London County Council school, at an estimated cost of £50. (2) We have received a requisition for an extension of mains in Crouch Hill to supply the North London Home for Aged and Christian Blind Men and Women in Hanley-road, together with a guarantee that the consumption of energy shall produce a revenue of not less than 20 per cent. per annum for the first two years of the cost of providing and laying the necessary distributing main, and having regard to this guarantee, we are of opinion that the requisition should be complied with, and have accordingly given instructions (the Council being in recess) for the work to be proceeded with under current contract at an estimated cost of £200. We have forwarded this estimate to the Finance Committee, and, subjected to its being adopted by them, we recommend (*a*) that the estimate of £200 submitted by the Finance Committee be approved; (*b*) that application be made to the London County Council for their sanction to the borrowing of a sum of £200 for the purpose."

Weymouth.—The newly-installed electric light works were inaugurated on Sept. 26. Messrs. Kennedy and Jenkin were the consulting engineers. The plans for the supply station were by Mr. Stanley Peach, F.R.I.B.A., Westminster, and the contract for the erection of the buildings was secured by Messrs. J. and H. Bagg. A complete modern plant has been laid down under the supervision of Mr. A. W. Wigram, A.M.I.E.E., A.M.I.E. Mr. Archibald Brown was clerk of the works. The engine-room is 60ft. long, 36ft. wide, and of a considerable height, and for the most part lined with white glazed bricks. It is spanned by a 12-ton travelling crane running the entire length of the room and worked by rope gear from the floor level. At present the room contains two sets of generators of 122 kw. each and four generating sets of 38 kw. The engines are identical in all respects, the smaller sets containing two and the larger three units. All the parts of these are interchangeable, so that the spare gear provided can be used in any of the 10 cylinders. Each engine has a duplicate source of power, and, as in the boiler-house, any section of pipes can be isolated from the rest. The engines are by Messrs. Reavell and Co., of Ipswich. They are of the single-acting compound type, running at 425 revolutions a minute. The steam in ordinary working will be condensed by water pumped out of the Backwater, for which purpose a pumping station has been built 20 yards from the end of the battery-room, but an alternative automatic arrangement is provided for turning the steam to the atmosphere. The larger engines each drives one generator of 122 kw. capacity, which work at a pressure of 480 volts. The two smaller engines each drives two generators of 38 kw. capacity, each generating current at a pressure of 240 volts. Arrangements have been made for further developments of the plant if required. That at present installed is capable of an output of about 400 kw., or, say, 560 h.p., being equivalent to the supply of 12,000 8-c.p. lamps. In the room at the end of the engine-room a storage battery of 240 cells has been installed by the Tudor Accumulator Company, and a motor-generator for charging it stands close to the battery-room. The station is lighted with Nernst and incandescent electric lamps, put up by Mr. W. D. Orchard, of St. Mary-street. The boiler-house, which is about 50ft. square, contains three Lancashire boilers, 28ft. long by 8ft. in diameter, suitable for working at a pressure of 160lb. per square inch. Coal is delivered from carts into bunkers, each holding about 50 tons, in front of the boilers. An economiser, consisting of 96 cast-iron tubes is fitted in the main flue, and through these the water is pumped on the way to the boiler. The water supply is procured from the town mains, and delivered into a tank with a capacity of 5,600 gallons placed on the top of the roof of the pumping-room, whence it is pumped by apparatus supplied by Messrs. J. E. G. Weir and Co., of Cathcart, Glasgow. There are six main cables and distributing mains in 8½ miles of streets. The cables laid are enclosed in wooden troughs boiled in tar, the troughs being filled with bitumen and covered with hard blue bricks. Across the Backwater Bridge and along the shore of the Backwater the cables are protected with steel armouring, those on the Backwater Bridge being supported on iron brackets outside the northern parapet of the bridge, and enclosed in a sheet-iron case. About 64 miles of conductors have been laid, including the cables for the public lighting. All the cables have been made and supplied by Messrs. Johnson and Phillips, of Old Charlton, Kent. A number of 800-c.p. lamps are on the Esplanade. The lamps, with their posts and gear, have been supplied by Messrs. Oliver and Co., of Woolwich. Each standard carries two small incandescent lamps. The remainder of the streets are being lighted by over 200 Nernst lamps of 40 c.p. to 150 c.p., put up by Messrs. Johnson and Phillips. The following contracts were carried out in connection with the electric lighting of the borough: Messrs. Johnson and Phillips, Old Charlton-road, Kent, for feeders, mains, roadwork, incandescent lamp posts and fittings, £11,413. 17s. 10d.; Messrs. Edwin Danks and Co. (Oldbury), Limited, Birmingham, for boilers at engine-house, £1,850; International Electric Engineering Company, Limited, London, dynamos (£3,192) and switchboard and motor-generators (£1,860. 9s.); Messrs. J. and H. Bagg, Weymouth, for electric lighting station, £8,490; Messrs. Oliver and Co., Woolwich, accumulator lamps, posts, and gear, £704. 3s.; the Tudor Accumulator Company, Limited, London, supplying storage battery, £1,156; Messrs. Aitou and Co., Willesden, for pipe work, feed pumps, economiser, ejector, condensers, etc., £2,889. 17s., together with an additional £96 for Weir twin compound feeding pump, and £220 for other works, in all £3,195. 17s.; Messrs. John Hitchin and Sons, Halifax, for overhead travelling crane, £280. 10s.—making a total expenditure of £32,142. The management of the new works under the supervision of the Electric Lighting Committee is in the hands of two skilful electricians of experience—Mr. R. G. Simpson, borough electrical engineer, and Mr. W. Drysdale, assistant borough electrical engineer. During the past week a number of the hotels and business premises were supplied by the Corporation. The contractors were W. D. Orchard, W. Gee, 28, Abbotsbury-road, Westham, and C. Tett, Queen-street. A number of Jandus arc and Nernst lamps are being installed.

PROVISIONAL PATENTS, 1904.

SEPT. 26.

20653. Invention for deadening live rail used for electric railway traction purposes, and also indicating when the said rail is alive. Richard William Scott, 3, East Mount-terrace, Haughton-road, Darlington.

20656. Continuous electric furnace for reducing metallic oxides or other compounds. Peter Auchinachie, 65, Chancery-lane, London.

20667. Improvements in intercommunication switchboard for telephone and other electrical instruments. John Alexander Romer, 1A, Lausanne-road, Peckham, London.

20670. Improvements in a commutating switch and circuits for controlling electric carriages and like purposes. Henry Francis Joel, 74, Windsor-road, Forest Gate, Essex.

20689. Improvements relating to the regulation or control of dynamo-electric machines and electric motors. Charles Prosper Eugene Schneider, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

20713. Improvements relating to electric transformers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

20714. Improvements in bearings for the shafts of delicate instruments. The British Thomson Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

20715. Improvements in insulations for edgewise-wound coils. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

SEPT. 27.

20725. Safety contact trippit for electric trains. William Coates and George Wright, 18, Armstrong-street, Bensham, Gateshead-on-Tyne.

20749. Improvements in trolley boom controlling apparatus for electric tramcars and the like vehicles. Samuel Hindley, 28, Rangeley-road, Sheffield.

20759. Improvements in and relating to mechanism for electrically-operated pianos and other musical instruments. Arthur Joseph Clarke, 60, Dinsmore-road, Balham, London.

20782. Improvements in the electrolytic extraction of zinc from its ores, and apparatus therefor. Arthur George Bloxam, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Société Anonyme d'Etudes Electro Chimiques, Switzerland.)

20783. Improvements in electrical telegraphs and controlling apparatus. Arthur Vyell Vyvyan and Leonard Newitt, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

20783. Improvements in the winding for monophase or polyphase alternating-current electric machines. Elektrizitäts Act.-Ges. vormals W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Nov. 12, 1903, being date of application in Germany.) (Complete specification.)

20791. A device for supporting electrical conductors. Charles Fredrick Bettmann and John Zapp, 13, Southampton-buildings, Chancery-lane, London. (Complete specification.)

20804. Improvements in and connected with wireless telegraphy systems. William Phillips Thompson, 6, Lord-street, Liverpool. (Gesellschaft für drahtlose Telegraphie m. b. H., Germany.) (Complete specification.)

20809. Improvements in electric furnaces. The British Thomson-Houston Company, Limited, 13, Cannon-street, London. (The General Electric Company, United States.)

20810. Improvements in electric furnaces. The British Thomson-Houston Company, Limited, 13, Cannon-street, London. (The General Electric Company, United States.)

SEPT. 28.

20833. Improved method of and means for operating the rail and wire points in overhead wire systems of electrical traction. Alfred Charles Virgin, Lloyd's Bank-buildings, Bristol.

20846. Circuit breaker. John Liddle, 154, St. Vincent-street, Glasgow. (Ernest Robert Hartman, United States.) (Complete specification.)

20849. Improvements in electric blow-outs and fuses. William George Allan, 55, Market-street, Manchester.

20877. Improvements in and relating to magnetic separators. Arnold Goodwin and William James Hollidge, 46, Lincoln's-inn-fields, London.

20896. Improvements in or relating to the manufacture of water-jackets, casings, and the like by electrolytic means. Alexandre François Bosquet, 18, Buckingham-street, Strand, London. (Complete specification.)

20898. Improvements in or additions to pipes or tubes for containing underground electrical cables or conductors. Edward John Chambers, 7, Staple-inn, London.

SEPT. 29.

20927. Improvements in the mode of suspending incandescent lamp-holders. James Mackersie, 41, Reform-street, Dundee.

20931. Improvements in the manufacture of switchboards for electrical purposes. Frederick Charles Ruddle, 29, Azalea-road, Blackburn.

20953. Improved electric igniter for simultaneously igniting and simultaneously or successively extinguishing gas-burners. Oreste Candi and Cesar Candi, 18, Buckingham-street, Strand, London. (Complete specification.)

20965. Improvements in and relating to the leading-in conductors for electric incandescent lamps and the like. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

20968. Improvements in or relating to central-station electric installations. John Somerville Highfield, 322, High Holborn, London.

20970. Improved braking device for electric motors. Arthur Hultqvist, 322, High Holborn, London.

20975. Improvements in or relating to electric lamps. Alfred Julius Boult, 111, Hatton-garden, London. (Ad. Wagner S. Brechtel und Co., Germany.) (Complete specification.)

20976. Improvements in or relating to electric traction. Robert Stewart Clouston, 111, Hatton-garden, London.

SEPT. 30.

20997. Improved means for controlling the flow of electricity into third or operative railway rails, or similar appliances for vehicular or other traffic, the said means being also available for signalling purposes. James Graham and Ramsey Kendal, North-Eastern Railway, Darlington.

21027. Improvements in apparatus for controlling the supply of electricity. Adolph Schneider, 1, Queen Victoria-street, London.

21028. Improvements in electrical measuring instruments. George Keith Buller Elphinstone and Harry F. Fast, 24, Southampton-buildings, Chancery-lane, London.

21038. An improved electric bell-push. Joseph Henry Hilliar, 94, Gore-road, South Hackney, London.

21040. Improvements in or connected with electric arc lamps. Frederick William Edward Schuer, 4, South-street, Finsbury, London.

21042. Improvements in and relating to electric arc lamps. Edwin Rudolph Grote and Milton Victor Ely, Palace-chambers, Westminster, London.

21043. Improvements in alternating-current electric motors. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

21045. Improvements in single-phase dynamo-electric machines. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

OCT. 1.

21081. Improvements in or connected with magnetic separators for ores or the like. John Thomas Dawes, 4, Clayton-square, Liverpool.

21131. Improvements in automatic electric switching devices applicable to flash advertising signs and the like. Percy Benson Harrison Seabrook and Henry Herbert Parkes Seabrook, 322, High Holborn, London.

21132. Improvements in and in the arrangement of switch-gear for electrical driving. William Phillips Thompson, 6, Lord-street, Liverpool. (Louis Dill, Germany.)

21135. Improvements in or relating to fuses for electric circuits. Alfred Richard Pritchard and Robert Whipp, 6, Lord-street, Liverpool.

21138. New or improved electromagnetic therapeutic apparatus. Emile Bachelet, 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, Oct. 2, 1903, being date of application in United States.) (Complete specification.)

21144. Improvements in electric lighting of trains. Henry Leitner and Richard Norman Lucas, Lynton, Dartnell-park, Byfleet, Surrey.

21145. Improvements in means for automatically controlling electric circuits. Henry Leitner, Lynton, Dartnell-park, Byfleet, Surrey.

21146. Improvements in accumulator plates. Henry Leitner, Lynton, Dartnell-park, Byfleet, Surrey.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Oct. 20, 1904.

NOTES.

Electro-Harmonic Society.—The society inaugurates its season to-night in the King's Hall, Holborn Restaurant, with a concert of which we gave particulars last week. Mr. J. S. Raworth will take the chair at eight o'clock.

Institution of Mechanical Engineers. — This institution opens its session on the 21st inst., when Mr. R. M. Neilson will read a paper entitled "A Scientific Investigation into the Possibilities of Gas-Turbines." The dates of other general meetings are as follows: Nov. 18, Dec. 16, Jan. 20, Feb. 17 (annual general meeting), March 17, and April 14. The anniversary dinner is fixed for April 13. Graduates' meetings will be held on the second Monday in each month.

New Publications.—"The Testing of Continuous-Current Machines," by C. Kinzbrunner (London: Harper Bros. 6s.); "Electric Furnaces and their Industrial Applications," by J. Wright (London: Archibald Constable and Co. 8s. 6d.); "Smoke Prevention and Fuel Economy," by W. H. Booth and J. B. C. Kershaw (London: Archibald Constable and Co. 6s.); "Electric Lighting for the Inexperienced" (the Wallet Series of Hand-Books), by H. Wallet (London: Edward Arnold. Paper 1s., cloth 2s). We learn that Messrs. F. H. Parshall and H. M. Hobart have in hand a new and important work on electric traction of an exhaustive nature, which will shortly be published by Messrs. A. Constable and Co.

Pyroradioactivity.—Mr. T. Tommasini contributes a paper on this subject to the *Arch. Sci. phys. nat.* Metals, when heated by an electric current, become radioactive and are capable of discharging electroscopes, etc. All the metals emit rays capable of discharging either electrification, but the difference between the two actions is generally very great. Iron, copper, and platinum produce a more rapid discharge of negative electrification, whilst for silver and zinc the opposite is the case. If the current increases, however, the difference between the two effects tends to disappear, and at bright incandescence the metal discharges both electrifications almost equally. The radioactivity of a metallic thread heated to redness by a current diminishes along an asymptotic curve, but its power is regained by rest for some time, or by light friction. When the radioactivity has become weak it continues for some time after the heating of the current, but is lost if the wire is struck. A mantle of glass or aluminium surrounding the wire also becomes radioactive. Three types of emissions exist: the α, easily arrested by screens, the β, more penetrative, and the γ, which discharge either electrification, induce fluorescence, etc. They are, however, less penetrative than the γ-rays of radium.

Wireless Telephony.—Experiments in wireless telephony have lately been conducted by a naval man in Monmouthshire. As the invention has not yet been patented a detailed description is not available, but the reports concerning it do not err on the side of pessimism. It is proposed that the receivers and transmitters shall consist of three classes—first, long distance; second, medium distance; and third, short distance. For short distances the inventor states that a dynamo is neither necessary nor desirable, as it destroys the tone of the voice. He found that eight ordinary cells with a good coil would carry the voice over five miles of sand, so as to be quite audible and recognisable. For 10 miles he uses 12 up to 20 cells, but no dynamo. For very long distances greater power would be required, and a small dynamo necessary. It is further stated that for land messages a central station would not be needed except under certain conditions, and that the tall poles used in wireless telegraphy would also be unnecessary. The apparatus is reported to have operated with considerable efficiency at 10 miles, the limit of the experiments, but the inventor expresses confidence that the system can be used for long distances.

Rontgen Rays in Cable Factories.—It has been known for some time that Röntgen rays could be advantageously employed in connection with cable testing, and a portable apparatus suitable for the purpose has, according to the *Elektrotechnischer Anzeiger*, been put on the market recently by the Elektricitäts Gesellschaft Sanitas of Berlin. The object in view is the detection of impurities, air bubbles, etc., in the insulating covering of the cable during manufacture. The apparatus consists of a case mounted on an iron frame on wheels and containing the induction coil and condenser. The whole can be readily moved about by means of the handles provided. One side of the case is removable, to permit the interrupter and the motor working it to be easily inspected. A switch panel is also fitted containing two fuses, adjustable resistances for varying the speed of the interrupter motor, and for altering the primary current and main switches for the motor and for the induction coil. A framework is fixed over the top of the case and carries two roller guides for the cable under test. Beneath these guides the Röntgen tube is held in a wooden clamp, and above them an adjustable fluorescent screen is fixed. As the cable is drawn past any irregularities in its structure are reproduced on the screen. By enclosing the screen in a light-proof covering the test can be readily carried out without darkening the room in any way

Personal.—We hear that Mr. A. W. Heaviside, I.S.O., M.I.E.E., first president of the Newcastle-on-Tyne Section of the Institution of Electrical Engineers, has retired from the position of superintending engineer under the Post Office, having taken advantage of the age limit. We are pleased to note that Mr. Heaviside has come to London, and that in future his address will be 12, Tring-avenue, Ealing Common, W. Of the work done by this engineer at Newcastle we have a very high opinion. In telegraph work Mr. Heaviside was responsible for the development of the telegraph system in the North-East of England. For many years he enjoyed the distinction of being practically the only telephone engineer in this country who controlled a fairly large exchange not belonging to the National Telephone Company, which he developed on the Bridge system (which he invented, and also secured privacy). As Mr. Heaviside is undertaking consulting work, his experience will be now at the disposal of anyone who may wish his advice either in telephone matters or in electric lighting undertakings. The work carried out under Mr. Heaviside's control when the first station of the Newcastle-on-Tyne Electricity Supply Company was constructed was also of a pioneering nature, and his control of that undertaking as consulting engineer lasted for a large number of years.

Electric Railway Practice.—The opinion expressed by Mr. Philip Dawson in "Modern Electrical Practice," that the third rail will become obsolete in a few years, receives confirmation from Prof. S. P. Thompson, who contributes the following to the daily Press: "In view of the numerous fatal accidents which have occurred at the 'live rails,' lately laid down for electric propulsion on some of our railways, the public is naturally beginning to ask for something more than a makeshift protection. Unfortunately, neither the public nor the not-electrically-trained railway engineers appear to realise that the 'live rail' is itself already an obsolete device, discarded in the latest types of electric railway. In 10 years' time there will probably be no 'live rail' left. I am no lover of overhead wires or

Digitized by Google

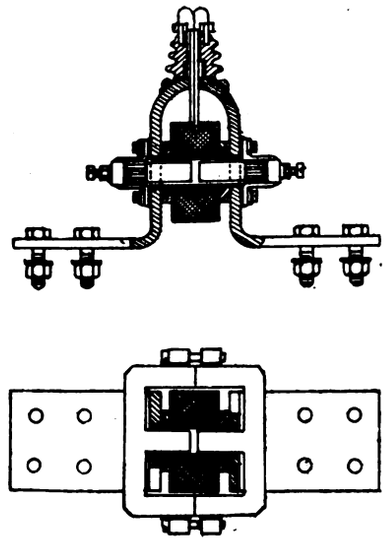
conductors in places such as our city streets, where they endanger the public; but if there is one situation where overhead conductors can be placed and maintained safely, that situation is over a railway, particularly an underground railway. Already the 'live rail' has been discarded in at least two places in the United Kingdom. It is an engineering blunder. I would therefore ask whether the time is not ripe for public opinion in some effective form, such as a departmental enquiry, to step in and prevent the railway engineers in England from committing our railway systems any further to this dangerous and unnecessary device."

Glasgow Technical College.—The Scientific Society of this college opens its thirteenth session on the 15th inst., when Mr. R. D. Munro will deliver his presidential address. The following is the programme for the season: Oct. 15, presidential address, by Mr. R. D. Munro, M.I.Mech.E.; Oct. 29, "The Law of Workmen's Compensation," by Mr. W. Boyd Anderson; Nov. 12, "The Diesel Internal-Combustion Engine, as applied to Electrical Generation," by Mr. A. J. Lawson; Nov. 26, "The Electrical Drive of Large Reversing Engines Working Intermittently," by Mr. Maurice Georgi; Dec. 3, symposium; Dec. 10, "Electro-metallurgy—Some Notes on its Present Position," by Mr. John D. Mackenzie; Dec. 17, thirteenth anniversary dinner; Jan. 21, "Notes on Toolroom Organisation and Practice," by Mr. George Blair; Feb. 4, "Kathode Rays and Allied Phenomena," by Prof. Blyth; Feb. 18, "High-Speed Tool Steels from the User's Point of View," by Mr. E. H. Robertson; March 4, "Steam-Generators and their Failures," by Mr. George Ness; March 18, "Independent Condensing Plant," by Mr. Charles Day; April 1, annual general meeting. At the annual general meeting it was agreed that the annual subscription for members be increased from 5s. to 7s. 6d., and for student members from 2s. 6d. to 5s., to enable the society to undertake the publication of papers. The council trust that this development will receive the hearty and united support of all members.

Dundee.—Reference has already been made in these columns to the practice of certain customers who generate power for themselves in using the municipal system merely as a stand-by after the Corporation have incurred considerable expense for equipment. The authorities appear to have now realised the position of affairs, and have given a general approval to the report presented by Mr. H. Richardson, the borough electrical engineer, last week, in which he recommends that the Corporation should follow the example of other towns, and obtain the insertion of a clause in their Act to the effect that no person having a separate supply should be entitled to obtain energy from the Corporation unless he agreed to take a reasonable minimum—say £7 per kilowatt per annum, which represents an approximate average of the terms prevailing in other towns. Apparently the Corporation have not at present decided to apply for the inclusion of such a clause, but Mr. Richardson has been instructed to negotiate with the customers coming under this head upon the lines indicated, so that the authorities have presumably awakened to a sense of the fatuity of giving a supply merely as a stand-by. We notice, by the way, that the Corporation have decided to substitute modern cables for the copper strips in their lighting distribution system. This will entail an expenditure of about £3,000, and is expected to result in materially increased efficiency.

The Telegraph, Telephone, and Cable in War.—This subject was treated in a paper read before the International Electrical Congress by Major S. Reber, of the U.S. Army, and we are indebted to the *Electrical World* for the following abstract of same: "The use of electrical means of communication is now absolutely necessary to success in war, not only in the grand strategical combinations of a compaign, but also in the varying technical situations on the field of battle. The development of the use of the means of communication in war has been along lines similar to those of commercial practice. The engineering principles are the same, but the operative conditions are more exacting and difficult. The essential requirement is absolute certainty of service, independent of dictates of economy. The service of communication is separated into field and fortress work. The fortress system consists of the permanent lines, usually underground, the details of which are zealously preserved as Government secrets. For armies operating in the field a complete chain of communication should exist from the outposts to the main base of operation. By the use of light field cable and bare wire a detached cavalry column can be connected during its movement with the main body. The paper contains an historical sketch of the use of electrical means from 1839 down to the present time. The part played by the cable in the history of recent years has completely proved that its *rôle* is scarcely inferior to those of the military and naval forces themselves. In the war of the future between two naval powers, the result will depend largely upon coal and cables."

Transformer Exhibits.—The detailed construction of the Siemens and Halske transformers exhibited at St. Louis is shown in the accompanying illustration, which we



reproduce from the *Electrical World* of New York. These transformers are used in connection with the firm's recording instruments in the cases of very heavy alternating currents The plane of winding of the secondary coil is at right angles to the primary current loop, and this transformer gives results independent of frequency, and uninfluenced by neighbouring currents. The exhibit also includes a number of potential transformers, which are built as high as 30,000 volts, for use in testing high-tension apparatus.

Electrical Club for Birmingham.—The proposal to form an electrical club for Birmingham, concerning which we published a communication from Mr. W. Dalby last week, looks like bearing fruit. A meeting was held at the Colonnade Hotel on Saturday night, when Mr. J. W. Innis presided over a gathering representative of the Post Office Telegraph Branch, the National Telephone Company, Municipal Technical School, Midland Railway Telegraph Department, and the electrical trade. The chairman stated that for some considerable time a feeling had existed amongst the allied workers in the electrical trade that a club or institute should be formed, the membership of which it was proposed should be confined to those engaged in the manufacture and use of electrical apparatus and machinery in all its aspects. It was thought that a club of

Digitized by Google

the character suggested would be of considerable value to the members engaged in the trade. The basic principle would be mutual, social, and intellectual help to its members. Several speakers expressed the opinion that the social side should be developed to its fullest extent, and that the subscription should not be prohibitive to the ordinary worker. After some discussion, the following resolution was unanimously adopted: "That a committee consisting of seven be appointed to consider the advisability of promoting an electrical club, and to present a report at a subsequent meeting." Messrs. J. Innias (consulting electrical engineer), W. H. Whitehouse and W. Smith (Municipal Technical School), E. R. Wood (electrical engineer), H. W. Dipple (National Telephone Company), M. G. Waggot (Post Office), and W. Dalby (Midland Railway) were appointed a committee to give effect to the resolution.

Durham College of Science.—The annual report was presented last week to a meeting of the governors. During the past session there was a record entry of first-year students, but owing to a slight falling-off of second-year students, the total was reduced from 513 to 507, notwithstanding which the amount received in fees reached £8,170—the highest in the history of the college. A regrettable diminution is noticeable in the number of colliery engineers and miners who attended the special Saturday lectures. The corner-stone of the final section of the college was laid in the course of the year, and the subscriptions for the completion of the buildings have reached over £30,000. The report observes that one of the most anxious concerns of the executive must now be the formation of an endowment fund to secure and ultimately to increase the emoluments of the teaching staff. A benefactor has presented £1,000 as a nucleus of such a fund, and it is hoped that other donations will speedily follow. The executive have urged the claims of the college upon the Government and the local authorities, and in February last an influential deputation of colleges attended upon the Treasury, with the result that the Chancellor of the Exchequer made a substantial increase in the grants, which may be further enlarged this year. The expenditure for the year, including £14,077 for salaries and fees of staff and examiners, amounted to £20,759, leaving a deficit of £1,182. Lord Armstrong, Dr. Hodgkin, and Mr. R. Redmayne were re-elected to the council, to which Mr. C. Cochrane, Sir Andrew Noble, the Hon. C. A. Parsons, and Mr. G. E. Henderson were also appointed. The name of the institution has been changed to "Armstrong College, Newcastle-upon-Tyne, in the University of Durham."

Goods Traffic.—The Vice-Chairman of the London County Council Highways Committee, interviewed the other day in reference to Mr. Bellamy's suggestion that tramways should be used for bringing agricultural and dairy produce into the towns, remarked: "London is not ready yet for its trams to be used to carry agricultural produce, but I believe we are bound to see something of the kind in the immediate future." At the present time such a scheme is not feasible, for the simple reason that the cars do not penetrate far enough; but with the network of tramways that will ere long connect the Metropolis with rural districts in all directions, the proposal may come within the sphere of practical economics. Of course, it will be a question at first of negotiations between the outside authorities and the County Council. This will be necessary in order to secure through services for passengers. Then as the vice-chairman proceeded to point out, it would be no use to bring market produce to the present termini, as that would entail goods brought to Covent Garden from, say, Kent being unloaded at the bridges. This provides an additional reason for sanctioning the Council's application for power to extend their system over the river. While, however, the suggestion offers a prospect of a substantial load factor during the night, the Council are prudently devoting their energies at present to mastering the intricacies of passenger traffic. Mr. Bellamy's idea may bear fruit earlier at Glasgow, where the Corporation contemplate instituting municipal cemeteries, in connection with which it is suggested that the Tramway Committee should make arrangements for accommodating the cortège. This sombre method of increasing the revenue of tramway undertakings is common among our Transatlantic cousins.

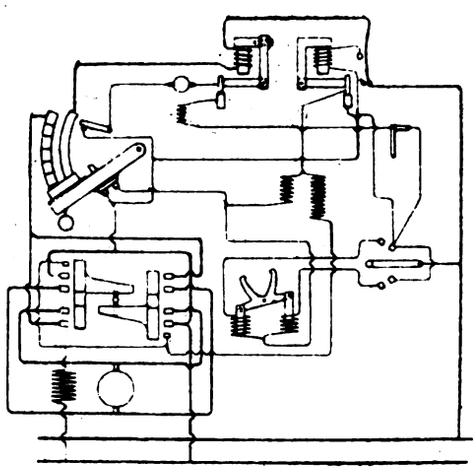
The Alternating-Current Theory of Transmission Speed over Submarine Telegraph Cables.—In a paper presented to the International Electrical Congress, Prof. A. E. Kennelly remarks that the law of cables enunciated by Kelvin in 1855 has been found inapplicable to overhead land-line telegraphy and telephony, and the working theory of telephony has therefore grown up independently of that of submarine cables—an unnecessary and unnatural division. If, however, the theory of alternating-current transmission can safely be extended to include the case of signalling over submarine cables, then the same theory can readily cover every case of signalling over wires. Such a theory can be made not only very comprehensive, but also very easy. The paper outlines this application of general alternating-current theory to submarine telegraphy. In dealing with power transmission circuits operated at ordinary commercial frequencies below 100 cycles per second, a simple solution is reached by placing all the capacity in a lump at the centre of the circuit; and the results are sufficiently accurate for practical purposes. For higher frequencies, however, such as are presented in telegraphy and telephony over long circuits, the method of lumped capacity is usually unreliable, and hyperbolic formulæ must be resorted to if simple expressions and arithmetic are desired. Hyperbolic trigonometry is, therefore, the natural and simple key to the solution of the problem. The theory is worked out on this basis and shows that the highest speed is obtainable from a given laid cable by placing a large condenser at the sending end, impressing the assigned maximum E.M.F. on the sending end, and making the impedance of the receiving instrument (assumed of maximum sensitiveness in construction) equal to the sending end impedance, but with the opposite angle.

Alternating-Current Motors.—A paper on this subject was presented by Mr. C. P. Steinmetz at the International Electrical Congress opened at St. Louis on the 12th ult., a summary of which is given in the *Electrical World*. The paper gives a mathematical discussion of all standard types of alternating-current motors—synchronous, induction, and commutator motors. Under induction motors the polyphase, single-phase, and single-phase condenser motors are treated, while of the commutator motors the polyphase shunt, polyphase series, plain single-phase series, inductively and directly compensated series (Eickemeyer, Steinmetz, Lamme), repulsion and compensated repulsion (Latour, Winter-Eichberg) motors are discussed at great length. The author treats the general alternating-current commutator motor as a machine consisting of two field coils in quadrature and two sets of brush circuits, also in quadrature, and derives general equations for expressing the E.M.F. in each circuit. The various types of motors differ according to in which circuits the impressed E.M.F. is zero (short-circuited), and in which circuits the current is the same (series connected). The treatment is essentially more complete than any previously given, since the short-circuit of the brush is taken into consideration. It is shown that of the various machines the repulsion motor possesses the highest starting torque and the most

Digitized by Google

rapid decrease in torque and power with increase of speed, and reaches zero torque and power at a definite speed. The single-phase series motor shows the lowest torque in starting, the highest at high speed—that is, its torque decreases least with increase of speed, so that in the case illustrated it almost approaches a constant torque motor. The compensated motor is intermediate between the repulsion and the series motor, but rather nearer to the former at low and to the latter at high speeds—that is, its torque is high at starting and at low speeds, but does not fall off as rapidly at high speeds as that of the repulsion motor. The repulsion is a low-speed motor, the series a high-speed motor, while the compensated motor is intermediate between the repulsion and series motors.

Regulation of Motors.—A patent has been obtained in the United States by Mr. G. Rennerfelt for an electric motor provided with an automatic regulator adapted to successively increase the speed of the motor, in combination with an acceleration controller connected to and driven by the motor and adapted to stop the regulator when the acceleration rate exceeds a predetermined limit. An account of this invention is given in the *Electrical Review* of New York, and is accompanied by a diagram, which we



reproduce. The inventor has in view the prevention of damage to motors from the current having been switched through in excessive quantities, particularly when the motor is carrying or moving a relatively heavy load, and also to obviate greater acceleration in starting than may be desired. A pilot motor is used for intermittently moving the regulator, its movement being stopped when the starting current exceeds a predetermined limit, and also when the acceleration rate exceeds a predetermined limit, and means are provided whereby both of these limits can be easily adjusted, so that the same apparatus may be used for motor installations with varying requirements. The objects of the invention are thus summarised: the prevention of an abnormal flow of current through an electric motor upon starting the same; the prevention of abnormal speeding of an electric motor upon starting the same; the provision of an arrangement for automatically rupturing the current flow through an electric motor in the event of overheating; to devise apparatus in which all the aforesaid three objects will result automatically, and in which the manual operation shall be limited to the closing of a single electrical contact; and to so arrange the apparatus that a minimum amount of energy will be wasted in its operation.

Transformer Decision.—The United States Circuit Court of Appeals recently delivered its decision in the case of the Westinghouse Electric and Manufacturing Company *v.* Stanley Instrument Company, reversing the judgment of the court below, which dismissed a suit to prevent alleged infringement of patents issued to Nikola Tesla relating to the conversion of alternating currents, on the ground that the plaintiff company had failed to establish a conception of the invention by Tesla prior to April 22, 1888, the date of a certain publication in Italy known as the Ferraris publication. The contention of the defendant company was that the Tesla patent was not directed to the utilisation of two-phased currents in a motor, but to a new way of producing the necessary two out-of-phase currents; that this specific way of producing two out-of-phase currents was old and well known in the art, and was old and well known as an equivalent of the method in a prior patent; that all the methods of producing two or more out-of-phase alternating currents set out the Tesla patents were, in and of themselves, old and well known in the art as means and methods of producing such out-of phase currents; and that their laws and limitations had been known and set out in a way not even approximated in accuracy or fulness in any of the Tesla patents. They further maintained that the feature of the Tesla patent involved merely the substitution of one means of obtaining two-phase currents for another means, which two means were old and well-known equivalents. In regard to this contention, the Court says: "Of course, all this was with the purpose of maintaining that there was no invention in any view of the patents now in issue. It unavoidably concedes, however, that, if there were invention, it was fundamental. When under special circumstances a particular practical application of a known principle proves to be of advantage in the arts, and yet the thought of making it had not occurred to those expert therein, such application, at times, involves invention. The corollary of this proposition is that, in cases of this character, where the originator has boldly struck out into a practical application, and stated it, though only in general terms, he has, for the most part, made his conception clear, even though the mechanical details have not been expressed or thought out. Therefore Prof. Main was right in testifying that, if Tesla made clear his conception in a general way, he made clear his invention, leaving the artisan skilled in electrical science to work out the practical details required in applying what was previously within the bounds of philosophical knowledge."

New Trolley Apparatus.—The ordinary trolley apparatus being quite unsuited to the San Francisco, Oakland, and San Jose Railway system, Mr. J. Q. Brown, the engineer-in-charge, devised a new type, an account of which is given by the *Scientific American*. The conditions were of an exacting character. This company operates trains up to eight-car formation, weighing, approximately, 350 tons, at speeds as high as 50 miles per hour, which require at times 2,500 to 3,000 amperes to be collected from the overhead conductor. A device was required that would operate at high speed on curves without leaving the wire in any direction. It was also requisite that it should have a range of not less than 6ft. in height for passing through subways and over surface railroad crossings. The apparatus consists of a double diamond iron frame made up of four conjoined frames. These are connected on each side by elongated joints to give stiffness, while at top and bottom the frames terminate in segmental gears. The gears at the bottom cause the side frames to move in unison, while the gears at the top keep the guards always in a vertical position, as shown. The roller is carried at the top on a shaft, the ends of which are fastened rigidly in a casting to which the guards are secured and on which pivot the segmental gears. The roller is made of 24in. of 5in. non-arcing metal tubing with hubs in each end, which have graphite bushings forming the bearing. The bearings are lubricated with oil carried in a cavity in the hub. The guards, which are

Digitized by Google

essential to the satisfactory operation at branch-off wires, are made of sheet steel pressed into the required shape. The arrangement of the tension springs, which keep the roller in contact with the overhead conductor, is worthy of notice. The springs are in practically the same plane as one side of the bottom frame. This arrangement gives practically a uniform upward pressure on the roller for all positions of the trolley wire, those now in use operating with a pressure of 24lb. Two trolleys are used on each train of two or more cars, as such an arrangement always ensures a continuous and low-resistance circuit to the motors. It has been found that this apparatus simplifies the overhead construction greatly, doing away with all trolley frogs and switches except at right-angle crossings, where a simple crossing of special design is used. The wear on the trolley wire is less than that caused by the ordinary wheel, and the life of the roller which is used is not known, as the original rollers are still in service after a year's use. These wear to a bright smooth surface, instead of being corrugated or pitted, as was expected. The device is practically noiseless, the rollers being packed with non-resonant matter to destroy the vibration. It is stated that the company, which has 26 of these trolleys in use, has found them work perfectly, and another railway has arranged for a similar installation.

Preparation and Electrolysis of Pure Molten Zinc Chloride.—A description of the tests conducted by Mr. Siegfried Grünauer appears in the *Zeitschrift fuer anorganische Chemie.* When commercial zinc chloride is heated until the evolution of steam is no longer perceptible and then electrolysed, either in a crucible over a free flame or in a U-tube, hydrogen is evolved at the cathode, the amount of hydrogen gradually diminishing until finally only zinc separates. As various specimens of commercial zinc chloride exhibit different behaviour on being electrolysed, the author has studied the conditions for the preparation of pure zinc chloride. The experimental conditions under which the various specimens of zinc chloride were electrolysed are very fully described. Those specimens which were readily electrolysed were found to contain ammonium chloride, and the influence of ammonium chloride on specimens of zinc chloride, which suffered electrolysis with difficulty, was accordingly investigated. In none of the latter cases did the separation of zinc take place at once. Experiments were next conducted with mixtures of zinc chloride and ammonium chloride in varying proportions, the mixtures having been dehydrated at 260deg. as far as possible. Another set of experiments is described where the mixtures were dehydrated with dry hydrogen chloride. With increasing amounts of ammonium chloride, the electrolysis proceeds with less ease; the molten masses remain free from zinc dust, but the preliminary evolution of gas at the cathode persists for a long time. The most favourable result was obtained with a mixture in the proportion of 11 mols. of zinc chloride to 1 mol. of ammonium chloride. The gases evolved at the anode were chlorine, hydrogen chloride, oxygen (resulting from the moisture still retained by the fused ammonium chloride), carbon monoxide or carbon dioxide (resulting from the oxidation of the carbon poles), and nitrogen (resulting from the oxidation of ammonium chloride by chlorine), whilst hydrogen, ammonia, and nitrogen were evolved at the cathode. The amounts of these gases were determined by gasometric methods. Anhydrous zinc chloride is prepared by heating ordinary zinc chloride which has been dehydrated, as far as possible, with concentrated hydrochloric acid. It may also be prepared by passing dry chlorine into fused zinc, or by adding zinc to molten lead chloride. An apparatus is described by means of which zinc chloride was dehydrated by a stream of hydrogen chloride. The electrolysis of pure zinc chloride was next studied under varying conditions of current strength. A description of the separation of iron and zinc by the fractional electrolysis of their fused chlorides is given. Mixtures of zinc chloride with potassium and sodium chlorides respectively were also electrolysed with varying current strengths. The metallic cloud, which separates during the electrolysis of zinc chloride at the initial stage, has a lustre like that of mercury.

The American Tour.—After the Electrical Congress at St. Louis, described in our last issue, the party left on Sept. 17 by special train for Pittsburg, where the visiting delegates were divided into six groups, and, under the guidance of members of the local branch of the American Institute of Electrical Engineers, were taken by chartered trolley cars to the various industrial establishments. One party went to the Carnegie Steelworks at Homestead, another to the Edgar Thompson Steelworks at Bessemer, another to the factory of the Nernst Lamp Company, another to the Westinghouse Electric and Manufacturing Company's works at East Pittsburg, another to the works of the Westinghouse Air Brake Company and of the Union Switch and Signal Company, and the sixth made a general tour of all the places, paying only a brief visit to each. Special attractions were provided for the ladies. Later the party reunited at the works of the Westinghouse Electric and Manufacturing Company. Here a section of one of the largest aisles in the new east machine shop had been cleared for the occasion, and served admirably as a reception room and banquet hall. Tables had been arranged in the form of a figure 8, with covers laid for 400. The hall was decorated with the colours of the various nations represented, and was illuminated by Bremer arc lamps, while Cooper Hewitt lamps were provided for a photograph which was taken when the guests were seated. Mr. George Westinghouse, in appropriate remarks, expressed his pleasure at the opportunity of meeting and greeting the guests of the evening. After a pleasant evening, the guests were conducted to the railroad station near by and embarked on the special train waiting to carry them to Washington, where they arrived early on Tuesday morning. A visit was paid to the new buildings of the National Bureau of Standards, after which the visitors were conducted to the Capitol, and thence to the new Congressional Library by members of the local entertainment committee. Having inspected these buildings, a luncheon was served in the café of the library building. The party then divided into groups, each group being taken in charge by a member of the local committee and conducted to a specified point of interest or group of places. The various divisions united for dinner, after which the special train left for Philadelphia. On Wednesday the party were conducted over the chief electrical works of Philadelphia, and were then entertained to luncheon at the Bellevue-Stratford Hotel, where the mayor delivered an address of welcome. Subsequently the party returned to New York in time for the "Arabic," which left for England the next day. In the interim, however, the party were entertained by Mr. T. A Edison at his laboratory at Llewellyn Park, while in the evening the visitors assumed the function of hosts, and entertained the members of the New York committee and others to a farewell supper at the Waldorf-Astoria. President Gray and Colonel Crompton spoke felicitously of the success of the visit, and of the cordiality which had been extended on every hand, suitable responses being made by President Arnold and others. A large number of members of the American Institute attended at the White Star dock on the Friday afternoon, when the "Arabic" left for home.

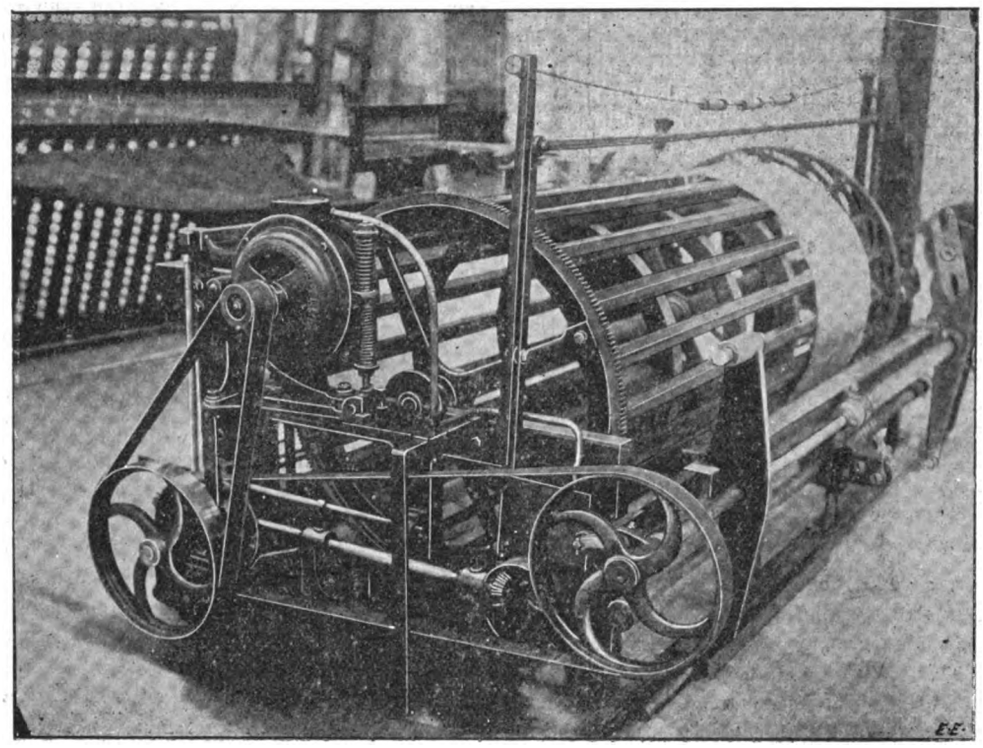
THE USE OF ELECTRICITY IN WEAVING FACTORIES.

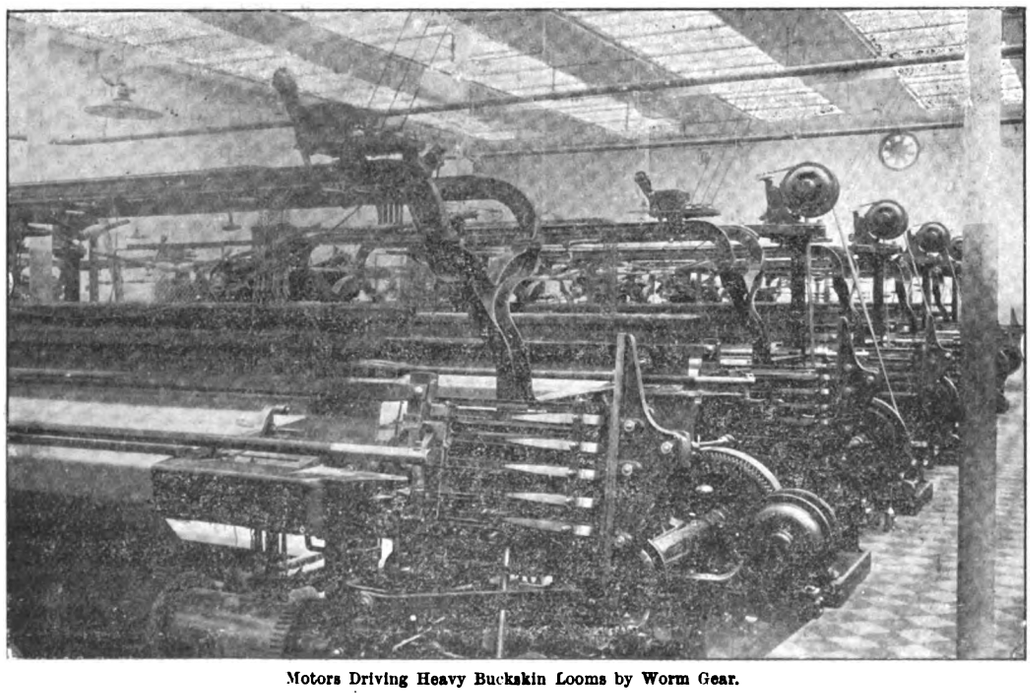
BY DR. ALFRED GRADENWITZ

The use of electricity in spinning, weaving, and finishing factories has for a long time been practically limited to the lighting of the shops. Incandescent lamps proved especially advantageous in this connection on account of their easy handling and adaptability to any special conditions, as well as of the fact that any danger of fire is practically eliminated by their use. Whereas incandescent lamps are being employed for the individual lighting of single machines, arc lamps have to be resorted to wherever the general illumination of whole machine shops is concerned. By their use a more uniform and stronger illumination than in the case of incandescent lamps of the same candle-power is secured with equal consumption of energy, while this illumination will approach daylight, especially as regards the distinction of colours. Such arc lamps are fitted with ground-glass globes, so that the light thrown downwards is dispersed to a great extent, the remainder being thrown from the glass globe on to the ceiling of the rooms, which, being painted in white, will reflect it downwards. As, therefore, electricity had long been a familiar feature in weaving factories, its application for power purposes was greatly facilitated.



Electrically-Driven Beaming Machine.

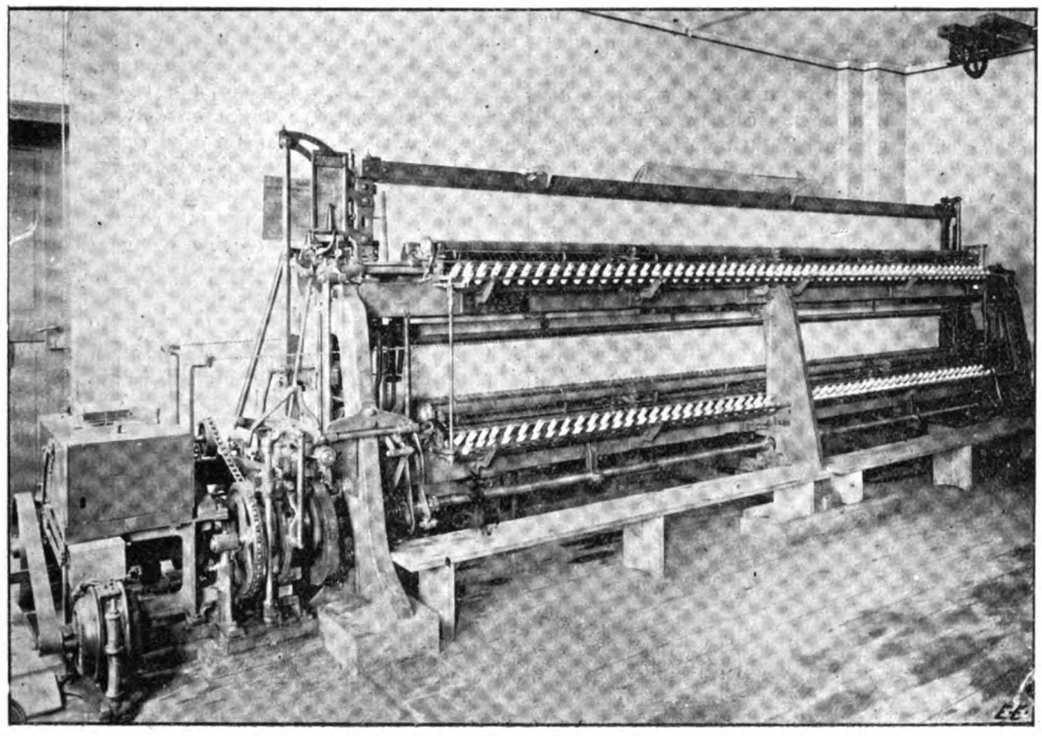
About 50 years ago the whole weaving trade was practically a domestic industry. In the factories themselves warps were only made by means of hand-driven machinery. After receiving these warps and the corresponding woof, the weavers had to do the further working of the warps at home, the completed fabrics being delivered at the factory. This process of manufacture was continued for years, until the mechanical loom was invented and gradually improved so as to be adopted on an ever-increasing scale. These mechanical looms, being capable of a much more continuous and rapid operation than the ancient hand-driven looms, were installed in workshops, the workmen now operating wholly in the factory itself, so that domestic industry eventually was practically replaced. Like the method of



Motors Driving Heavy Buckskin Looms by Worm Gear.

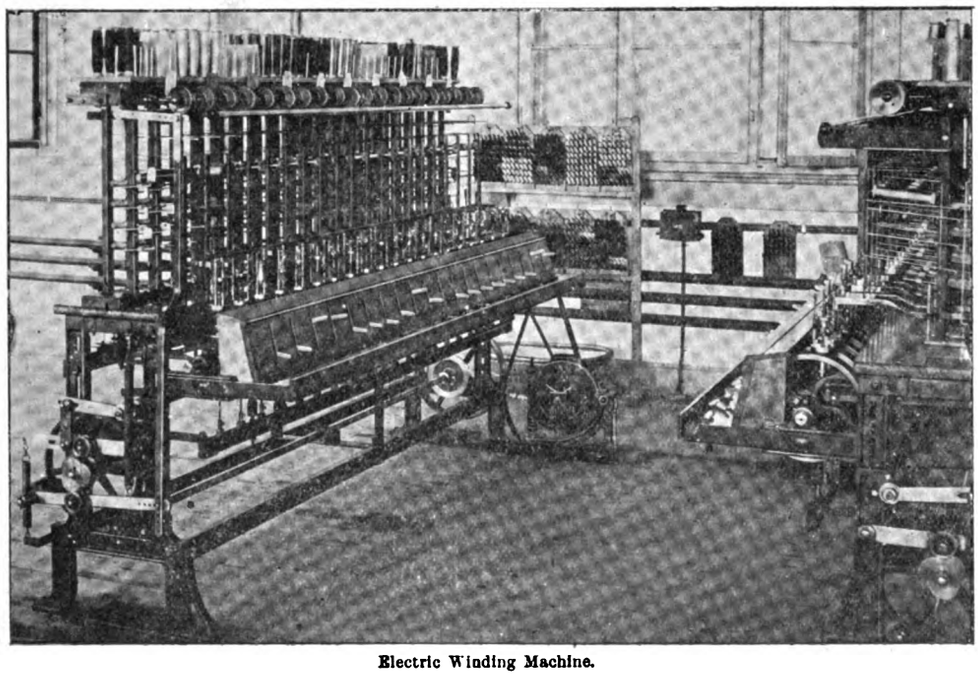
Digitized by Google

operation, the raw material has been considerably improved. Whereas once upon a time the warp and woof material had in most cases to be dyed previously, the raw material at present used is nearly always worked in an undyed state, the dyeing process taking place afterwards on the completed fabrics.



Shuttle Embroidering Machine.

As regards the operation of these mechanical looms, shafting driven by a steam-engine and actuating several groups of looms were used in the beginning. Whereas these shaft and belt transmissions, as a matter of course, received in course of time many improvements and simplifications, further advances were to be anticipated from the adoption of electricity, which had revolutionised so many other provinces of industry. This was the less difficult as the existing belts could be driven immediately by means of electromotors, while the weaving machines themselves remained practically unaltered; moreover, the same type of motor could be employed for many different workshops. The necessity of adapting the electromotors to the special characteristics of the machines driven by them would, however, become more and more evident in course of time, it proving suitable in many cases to adopt a special electromotor for each machine, thus using what is known by individual drives. This, it is true, was not possible before rotary-current motors could take the place of continuous-current motors, where the commutator of the armature, being made up of many individual segments, required a large amount of continuous superintendence, while being subject to considerable wear and tear. Rotary-current motors, on the other hand, required, on account of simplicity of their design, no appreciable maintenance. They start readily and safely under full load, and are not so susceptible to energy oscillations during operation. Thus they allow of individual motors being introduced on a large scale. By the way, it is satisfactory to state that this use of electricity for the operation of individual looms allows of the domestic industry, which was disappearing on account of the overwhelming competition of factory operation, being preserved and in many cases restored to new life, any sanitary dangers of weaving being eliminated now, and persons of even limited physical strength being enabled to devote themselves to the art of weaving.



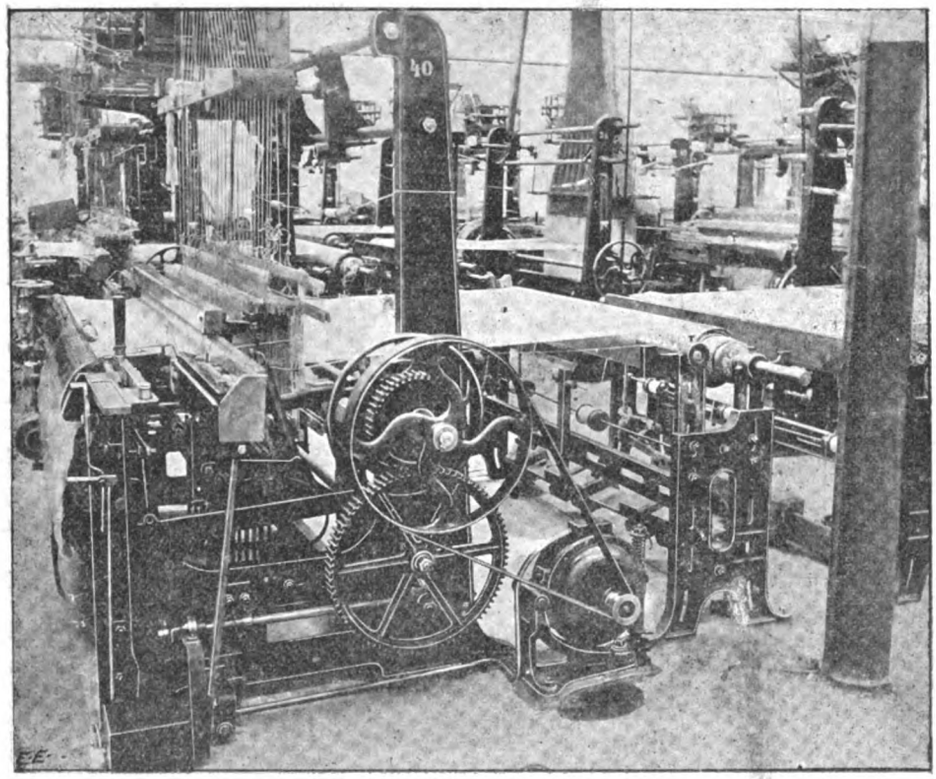
Electric Winding Machine.

Digitized by Google

Some typical instances of electrically-driven looms are represented in the accompanying photographs, kindly supplied by the Allgemeine Elektrizitäts-Gesellschaft, of Berlin. In the loom motor constructed by this company a short-circuit rotor is used, consisting simply of an iron core with notches arranged at the periphery and containing copper rods. On both front sides of the armature these rods are connected with one another by means of metal rings, no current being supplied to the rotating armature of the rotary-current motor. The working current from the mains has only to be introduced into the stators. No sliding contacts or brushes are thus necessary. An important feature is the easy and safe excitation of the rotary-current motor, even under full load, being much less sensitive than any other motor with respect to fluctuations of load and overloads as occurring during the operation. In virtue of their simple design, rotary-current motors are, further, smaller and lighter than direct-current motors of the same output, and nothing prevents them from being arranged in a most limited space. As these motors are fitted with shields supporting the bearings, both the coils of the stator and rotor are perfectly safe against external injury, convenient ventilating fans avoiding at the same time an excessive heating effect. The special rotary-current loom motor of the Allgemeine Elektrizitäts-Gesellschaft is, therefore, particularly simple and suitable for use in connection with weaving factories. The loom motor is connected to the machine to be driven by means of either gearings or belts, the number of revolutions being mostly too high to allow of its being operated direct.

In the case of a toothed gearing being used, a small driving wheel is mounted on the motor shaft, which gears with a larger toothed wheel mounted on the shaft of the loom to be operated. In the case of the speed of the loom shaft having to be altered, the small driving wheel of the motor will be replaced by a larger one containing a correspondingly modified number of teeth with the same pitch. As the diameter of the pitch circle is altered hereby, a modification of the distance between the centre of the motor shaft and the centre of the loom shaft will also be necessary, this being obtained by a convenient adjustment of the motor. This is effected by an eccentric bearing, capable of serving at the same time as bearing to the loom shaft. Any regulation of this bearing will correspond with a variation in the distance of both shaft centres. The speed of the loom shaft may thus be altered 30 per cent. by steps. The bearing contains two concentric sleeves, the motor being supported by the inner sleeve—the eccentric proper. After the distance of the centres has been regulated by rotating the eccentric bearing, the latter is fixed to the supporting arm of the motor, so as to make any further alteration in the relative position of motor and box impossible during operation. The motor is thus suspended like a pendulum, being liable to yield to the shocks occurring in the looms, oscillating with the eccentric bearing about the loom shaft to either side. The oscillation is limited by two spiral springs, retaining the motor placed below or above the toothed wheel to be driven. For many kinds of looms it is best to arrange the driving motor horizontally beside the toothed wheel to be driven, the motor being placed immediately between two springs, the lower of which is so designed as to compensate for the weight of the motor itself in addition to any possible shocks.

In one case of *belt gearing* being adopted the motor is mounted on a belt balance, designed in accordance with each special case. With belt balances for vertical belt operation, there is an angular jack to the upper arm of which the motor is attached. If the whole be installed on the ground, the weight of the motor compensating the tension of the belt will maintain the belt automatically stretched. As, however, the weight of the motor is too great and would result in too high a tension of the belt, the motor is further supported on the side opposite to its rotating shaft by two springs, compensating any desired fraction of its weight, the application of this belt balance in the case of an installation on the ground being shown in the illustration. The same arrangement may be used for horizontal belt operations provided it be attached to the wall or to a vertical column. This belt balance may equally be attached to the ceiling. A second kind of balance is used for horizontal belt operation of motors placed on the ground, whereas a third type is being used for vertical operation of the belts in the case of the motor being partly sunk into the ground. If a belt balance is not indispensable, motors with screwed feet are used mounted directly on the foundation or on special rails. The advantages from the single-motor driving of looms are first shown by the fact that each loom is completely independent of any other and capable of being connected or disconnected at will. Moreover, if a loom be stopped, no work for rotation at no load is consumed, whereas in the case of operation by shafts and belts, even if all the looms of one section be stopped, the main shaftings have still to be run. In the case of frequent pauses occurring in the operation,



Light Loom, operated Electrically.

Digitized by Google

the *cost of operation* will for both methods be about the same. If, however, unsatisfactorily designed and complicated transmission plants are replaced by electric motors for single driving, the cost of operation under certain conditions would be reduced.

The question of the operation above described should be considered, especially with new plants or additions to existing factories, a considerable saving being obtained in the first cost. The independence of the looms of one another in the case of individual driving is further shown by the looms not being affected when one loom is stopped, whereas in the case of operation by shifting, any disconnection or connection of a loom will result in a corresponding modification in the speeds of the remaining looms of the same group. Though of no great significance in the case of common fabrics and textures, experiments have shown that with finer goods, especially with silk fabrics, *a more uniform texture* is obtained in the case of individual driving. This fact is due also to the uniformity of speed with different loads as exhibited by rotary-current motors. This continuous speed will result also in a considerably lesser frequency of a rupture of the threads, the efficiency of the loom being thus equally increased to some degree. Further advantages of this kind of operation are the better illumination of the workshops as due to the absence of transmissions and belts; moreover, the dust inevitable with transmission operation, as well as the spitting of oil, is perfectly avoided, the cleanliness of the goods being thus increased.

The new motor is in a most simple way switched in and out, a switch-out being mounted beside the loom on the ground, being directly connected to the present lever of the loom, operating at the same time the brake. In order to connect or disconnect the loom it is, therefore, necessary only to adjust this lever. The rotary-current loom motor, therefore, affords a means of utilising completely any advantages of electric operation for all the machines used in weaving shops, the results so far obtained in similar factories being most satisfactory. But for other branches of industry, wherever small machines have to be driven individually, the loom motor should also prove suitable, as the considerations controlling the choice of a system of operation are dependent not only on the first cost or the cost of operation itself, but as well on the safety and easiness of the operation itself and the suitable independent arrangement of the various machines.

NOTES ON MOTOR-STARTING SWITCHES.

[CONTRIBUTED.]

(Continued from page 519.)

In the design of a perfect starting switch it should be impossible to stop the motor by the starting switch, or if it is possible, then a secondary device should be inserted to dealt with the induced shunt current. This may be part of the machine, say a high resistance connected across the ends of the shunt, or it may be an adaptation of the device mentioned above, and consist, as is the case with some of the higher-priced switches, of lamps or other high resistance momentarily connected across the shunt terminals at the time of make and break. The use of lamps for this purpose is not altogether satisfactory: they serve a useful purpose in showing the necessity for some external resistance closing the shunt circuit at these times, but they are liable to break, and as the operator will not see that they serve any useful purpose he will not replace them. In fact, in one case the writer found the operator had removed the lamps as he considered they were of no service on the starter, and could be usefully employed elsewhere for illuminating purposes. As before stated, this is one of the most important requirements, and no starting switch should under any circumstance be accepted in which due provision is not made for absorbing the induced current. The question is still further complicated, and assumes, if possible, greater dimensions when dealing with series-wound or compound-wound motors, and in these cases every precaution must be taken to prevent the bad effects due to the heavy induced currents from the series turns.

The fifth requirement is also one of considerable importance, and the true meaning does not yet seem to be grasped by all switchmakers. It is not sufficient to design a switch in which the lever moves at an even slow speed from one end of its range to the other. The process of so moving the starting lever consists of two parts. In the first place, there is the time during which the lever is making contact with the individual steps; and, in the second place, there is the time occupied by passing from one step to the next. The requirements under the two different conditions are entirely at variance. In order to have a steady start, and also to prevent fluctuations in the E.M.F. of the outer circuit, it is essential that current shall be supplied to the motor armature by easy gradations, and that there shall not be any sudden increase in the value of the current so supplied; it is also necessary that the motor attains the correct speed for the value of the E.M.F. for each increase in the current before a higher E.M.F. is applied to the armature. These requirements are met by permitting the lever to rest for an appreciable length of time on each contact. On the other hand, it is necessary, to prevent burning of the contacts, that the movement of the lever from contact to contact shall be instantaneous. It is evident, then, that a slow motion of the starting lever, such as that which obtains when the lever is moved by worm gear, is not altogether desirable, for while it fulfils one requirement, it does not the other. Several devices have been proposed to overcome this difficulty, and some of these will be described more fully in detail later, for it is possible to meet the requirement in several ways. In the first place, the switch can be designed to have a kind of jumping action, and, in the second place, only a small shunted current need be dealt with at the contacts. Each of these devices means a costly switch, as they entail the use of solenoids in the construction of the switch. Another device is to arrange the contacts in a series of steps as regards the horizontal plane, as well as in a series of steps as regards the vertical plane. The difficulty here is to arrange the switch so that the lever will fly back to the off position upon releasing the automatic no-volt device. The more familiar arrangement is to let sparking and consequent burning of the contacts occur, but to make these contacts easily renewable, and to treat the occurrence as ordinary wear and tear which cannot be prevented. It is in this particular that the liquid resistance starting switch holds its great advantage: there are no contacts to burn, and the lever, or rather its equivalent, the electrode, is only slowly immersed in the liquid.

The next requirement is one of the most difficult to deal with, and various authorities give different rules; in many places it is specified that the movement of the lever from one contact to the next shall not increase the current by more than 10 amperes, say. But this is not sufficient. Consider for a moment the conditions which obtain when a motor is started up. The first thing to be done is to excite the shunt coils, then to cause the armature to rotate. If the armature were held firmly at rest, then the circuit through the armature could be treated as a circuit having a resistance of y due to the armature alone plus a variable resistance x, which is gradually reduced as it is cut out by the action of the switch. But as soon as the armature commences to revolve the conditions are altered. There is then a counter E.M.F., which acts as an additional resistance induced in the armature windings, and the value of this counter E.M.F. depends upon the speed the armature attains, the shunt field strength remaining constant, except in as far as it is influenced by the armature reactions. Now, the condition for holding the armature fast at rest is only that of infinitely loading it, and when a motor is started from rest under load this condition is to a certain extent fulfilled. In the case of a small fan motor, there is practically the same condition obtaining whether it be started under load or not, but the difference between the conditions of starting under load or light load increases as the size of the motor is increased. Take the case of a 200-h.p. motor. Here we will assume that when started running light 10 amperes only are required; then for starting the machine only 10 amperes are requisite, and the motor will receive its full current by moving the starting switch to the second contact pieces, but when this

Digitized by Google

machine is running under full load 400 amperes are required, and as a greater starting current is required than the normal full-load current, it can be assumed that for starting 750 amperes are necessary. This means that to fulfil the requirements the switch must be fitted with 75 steps. Now, consider the operation of starting—so long as the armature is at rest it can be treated as possessing so much ohmic resistance, and the motor will remain at rest until a large proportion of the starting current has been supplied. It is probable that the starting switch lever will be moved over 60 of the steps before the armature commences to revolve at all, and the whole of the regulation of bringing the motor to its correct speed must then be carried out during the passage of the lever over the last 15 steps only. But even in this case the switch must be specially designed for the work, as under ordinary conditions of starting light or under under partial load only the armature commences to rotate sooner, that is, with a lower current, and the maker of the switch may reasonably rely upon the effects of a counter E.M.F. of the armature. In purchasing or designing a starting switch, the work that the switch has to do should be clearly defined, and if the motor is required to start frequently under load, and is at the same time a large-sized machine, then a larger current should be permitted to flow through the armature by each earlier movement of the lever from step to step, otherwise it is almost impossible to get good regulation on the last contacts. The rule should be as stated, and not that the movement of the lever from step to step only permits an increase of current of such-and-such a value, as the conditions as to what value of current flowing will affect the E.M.F. of the supply the least will alter with different circumstances.

The following two requirements have been dealt with in treating of other conditions. The only point that needs emphasis is that every care must be taken with the insulation of the various electrical portions, and that the insulating material should not be readily affected by moisture, dampness, etc, and should also be able to withstand great variations in temperature without deterioration.

The ninth condition is important, but it is questionable whether it is better to have these devices mounted on the same slab as the starting switch proper, or if it is not better to deal with them as necessary or rather essential accessories. In the case of the liquid starter there is no good automatic no-volt release, and therefore a minimum circuit breaker ought to form part of every motor equipment when a liquid starter is used. The difficulty of this is in arranging a path for the self-induced current. In the starter with metallic resistance the object of putting the no-volt release on the starter itself is to get the lever to fly back to the off position when the current is interrupted. There is no difficulty, however, in arranging a high resistance, so that on the opening of the circuit breaker it is connected across the shunt, as was shown in the case of the lamps connected to the auxiliary switch previously referred to. The great advantage of utilising a circuit breaker is that the sparking at the switch step contacts is eliminated entirely. If the no-volt release forms part of the starting switch, then it acts by causing the starting lever to fly back, and the armature resistance is broken by the lever leaving the last contact. On the other hand, if a minimum circuit breaker is inserted, the current both to the armature and the shunt circuits is broken at the circuit breaker, and as the knives of these are usually fitted with carbon break pieces, there is no burning away of any of the vital parts of the apparatus. The same remarks hold good with regard to the overload preventer. The overload preventer, however arranged, is nothing more or less than a simplified form of a circuit breaker. In many cases it consists of a device by which, if the current flowing through the armature at any instant exceeds a previously determined amount, then the two ends of the no-volt release bobbin are short-circuited, and the current is interrupted by the lever flying back, and is broken at the switch contacts in the manner already described, and the shunt being broken at the last contact, the motor may be seriously damaged.

It is readily apparent that it is not conducive to long life of the apparatus for the current to be broken at this place, owing to the damage done through ordinary burning of the contacts. There is, however, a greater evil apparent upon considering the question more fully. If the lever flies back, owing to the action of the release coil proper, it is generally because the current has been interrupted, and the flow through the shunt coils has ceased. On the other hand, if the lever flies back owing to the action of the overload preventer short-circuiting the ends of the release bobbin, the current through the shunt has not been broken until the lever leaves the last step. The result of this is that there is no path for the self-induced current of the shunt coils, for we have seen that the path provided is through the armature, and all connection between one end of the shunt coils and the armature is interrupted when the lever is not making contact with the steps. It is well known that a motor may break down owing to overloading, but it is far more likely that a motor will break down owing to the high induced E.M.F. due to the self-induction of the shunt. The addition of such an overload preventer as that which acts in the manner above described, and which is the most prevalent type met with in practice, eliminates one source of danger only by introducing into the apparatus another much more serious source of danger.

The whole of the difficulty can be eradicated by inserting a maximum type circuit breaker, and if this be done, it is only little more costly to add the no-volt attachment to this circuit breaker, and thus to fully protect the motor apart from the starting switch, which apparatus has other most important functions to fulfil. Another advantage of so arranging the apparatus is that in the case of any breakdown to the accessories, there is less danger of breakdown to the motor. In two cases which the writer has come across of the shunt release coil burning out, the shunt coils have also been pierced, owing to the failure of a path for the induced current. If the addition of these necessary and useful circuit breakers were more general in cases where a switch with metallic resistance is employed, they would also be more often adopted with liquid switches, where their presence is more necessary. In shipbuilding yards, engineering works, and kindred places the use of the liquid starter is very general, and, as it will withstand rough usage, it is a most serviceable piece of apparatus for exposed positions and for use by unskilled labour; but it has the disadvantage that there is no good liquid switch which can be fitted with automatic no-volt release. The most usual practice is to connect the shunt directly across the mains, so that the fields are always excited, and to use the liquid starter for dealing with the armature circuit only. This practice prevents to a very large extent the burning out of the shunt coils due to self-induced E.M.F., as the shunt circuit is not broken every time the motor is stopped, but at times—for cleaning purposes, for instance—it is desirable to interrupt the shunt circuit, and then there is danger of burning-out occurring. A more important objection is that if the motor be running at the time the generator stops, or if there is any other way of controlling the motor circuit, say through a double-pole switch, and the supply is stopped, it can be connected again directly through the armature with the motor at rest, and then we get the case of a motor being started without any starting switch. The only satisfactory method of overcoming this difficulty is to insert a maximum and no-volt circuit breaker in circuit with each motor. If this be done, then the circuit breaker and the starting switch should be so interlinked that the circuit breaker will remain closed when the electrode is in the liquid, while at the same time it is impossible to perform the operation of closing the circuit breaker unless the electrode is entirely clear of the liquid. There is one objection to this. The liquid is liable to escape from the tank, and a circuit breaker, being a delicate piece of apparatus, should not be subject to damp surroundings; further, a gas is frequently given off which attacks all metal work. For these reasons it is advisable to have the starting switch and the circuit breaker a little apart, and it may be difficult to satisfactorily interlink them in the suggested manner. In this case the circuit breaker should be designed so that it is impossible to close the main circuit if there is a short, or if the resistance of the circuit is so low as to permit a current higher than that at which the circuit breaker is designed to open to flow even during the operation of closing the circuit breaker. There are several ways of

Digitized by Google

fulfilling this condition: one of the simplest is to design the circuit breaker with two switches, one the main switch and the other a subsidiary switch. If the circuit breaker be so designed that the current will only flow freely through the apparatus when both switches are closed, and is also designed that the main switch can only be closed when the subsidiary switch is also previously closed, there is no fear of making the circuit, even momentarily, if there is a short on it.

The convenience of liquid starters is very great, and they have a most important future before them. The rough usage they will withstand, the ease with which they can be manipulated, their simple structure, and the impossibility of permitting the current to be increased through the armature either too rapidly or by jerks, make them of the greatest service, but before they can come into more general use no-volt devices must be attached, or else they must be used in conjunction with circuit breakers of the type indicated.

The tenth condition is one of the utmost importance, but it is more desirable in the case of the simpler switches than in that of those designed for special purposes, such as the controllers of teazer sets, etc. In many cases, owing to a want of skill in the manipulation of the starter, a little matter will go wrong, and if readily accessible this will receive attention and be put right, but if the working parts are hidden behind the slab, considerable time is occupied, and there is great liability for the apparatus to be neglected. In the more complicated switches this accessibility is just as desirable, but is not so essential. Here the apparatus is usually in the hands of some electrician, who, fully appreciating the importance of the starting switch, will note any peculiarity in its behaviour, and correct in time any defect.

The necessity of the eleventh condition is evident. As regards the last, it must be remembered that while theoretically there are 746 watts in the horse-power, yet in the case of motor work, owing to the absence of perfect efficiency, 850 or more watts should be allowed to the horse-power, and the starting switch should be designed on the actual brake horse-power, and not on the theoretical. In the same manner a fair margin should be allowed for overloading; in many instances the purchaser has no exact knowledge as to the power required by the machine which he wishes to drive, and this is frequently underestimated; therefore, both the motor and the starter should be designed to allow a reasonable amount of overloading. It is frequently found in motor specifications that the machine shall give such-and-such a horse-power for so many hours without heating above a specified amount, and shall be capable of developing 25 per cent. or 50 per cent. additional horse-power for periods not exceeding half an hour without any undue heating and without sparking. Provision is thus made in the motor for the overloading, but the same care should be extended to the switch, for it is upon the success or failure of this important part of the equipment that the life of the motor depends.

(To be continued.)

SHOREDITCH ELECTRICAL EXHIBITION.

The exhibition organised by the Lighting Committee of the Shoreditch Borough Council, which will continue until the 22nd inst., was opened on Monday by the Mayor, Mr. H. B. Bird, J.P. The Council have undertaken this function with the special object of bringing to the notice of the public the advantages of electricity for lighting and power purposes; and for the guidance of those contemplating its use, an office has been opened at the entrance to the exhibition, where the borough electrical engineer, Mr. C. Newton Russell, will supply every information. The Council, it may be mentioned, will allow a liberal graduated discount upon the charge of 2d. per unit for power. The exhibition is being held at the Pitfield-street baths.

The proceedings were inaugurated by a statement from the Chairman of the Lighting Committee, who was followed by Mr. Russell. The Mayor then delivered a short address and declared the exhibition open. In the course of the speeches reference was made to the advantages of electricity and its progress in the district. The efforts of the Lighting Committee, Mr. Russell, and the exhibitors in organising the exhibition were also acknowledged in appreciative terms.

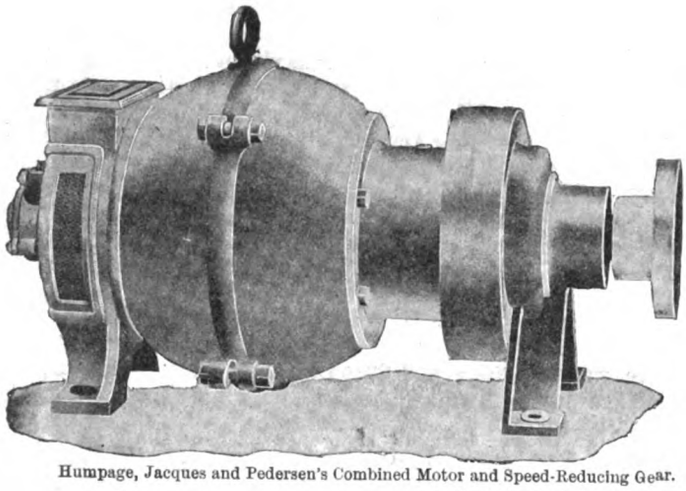
There are five-and-thirty exhibitors, and the last on the programme—Babcock and Wilcox, Limited—are the first to catch the eye, their stall being in the corridor leading to the hall. Here are models of their well-known patent watertube boiler and mechanical chain-grate stoker. Photographs are to be seen of Guttmann's patent water-softening and purifying plant, and a turbine tube cleaner for removing incrustation from the interior of the boiler tubes is also on view. Entering the hall, the visitor first encounters the stall of Messrs. Isenthal and Co., of Mortimer-street, Cavendish-square, W., whose speciality is heating apparatus. The Crypto Electrical Company show a variety of their motors and dynamos, some of which are used by the Government. Messrs. J. Defries and Sons, Houndsditch, are showing the "Defresque" translucent enamel glass, which will be found effective for electric signs and facias where it is desired to obtain equally good results by night and day. They are also exhibiting the "Defresque" brilliant mosaic, an improved process of manufacture which yields highly luminous results. Besides these, they have a good display of Stewart arc lamps, and Wirt rheostats, theatre dimmers, and the special dynamo brushes which are described in our "Trade Notices and Novelties" column this week. Messrs. A. W. Penrose and Co. have an extensive display, comprising an electric goods lift, the high economy of which the makers guarantee; a combined power and lighting switchboard constructed for the Finsbury Distillery; a group of standard motors; a number of machine tools, each driven by its own motor; motors for printing work; and a quantity of domestic apparatus. Messrs. H. F. Joel and Co. show as specimens of their "Zone" dynamos and motors a 5-h.p. motor driving a large band saw, and a 1-h.p. motor driving a platen printing machine.

In the centre of the building Messrs. Crompton and Co. and the General Electric Company, of London, Witton, and Manchester, present representative displays. The former show motors from ¼ h.p. to 10 h.p., some fitted with reduction gear, rendering them suitable for hoists, etc. Special attention is directed to their buffing motors of from $\frac{1}{16}$ h.p. to 1¼ h.p. Messrs. Crompton are also making a fine display of measuring instruments. A current of ·015 ampere deflects to the limit of its scale any voltmeter whose scale is calibrated from zero, and in the case of a voltmeter having an open scale, ·015 ampere deflects the needle to the centre reading. These instruments have a special arrangement for removing them from the switchboard without access to the rear of the board. The General Electric Company show a multiplicity of apparatus from motors to cigar-lighters. A couple of Witton motors can be seen driving a band saw and a box-making machine respectively. These motors are made in all sizes from 1 h.p. to 75 h.p., but space compels the exhibits to be restricted to 10-h.p. motors. To compensate for the limited size of the machinery on view, the company are exhibiting photographs of some of the big plants they have laid down. Numerous types of telephones, bells, lamps, drills with their own motors, fans, and other apparatus are on view, and the company's representative also showed us some very neat medical coils, which are meeting with an extensive sale among physicians, thus testifying to the spread of electro-therapeutics. It may be added that, to encourage the use of electrical power, the company are offering small motors by the instalment system on very reasonable terms. In connection with the company's exhibit there is a demonstration of the processes employed in the manufacture of the Robertson electric lamp, which is very much in evidence throughout the building, while at intervals throughout the day wireless telegraphic operations are conducted for the edification of spectators. Messrs. Humpage, Jacques, and Pedersen are showing speed-reducing gears to couple to motors, and also self-contained combined gears and motors, of which we give an illustration. Their electric sack hoist, which was in operation throughout the day, attracted a

Digitized by Google

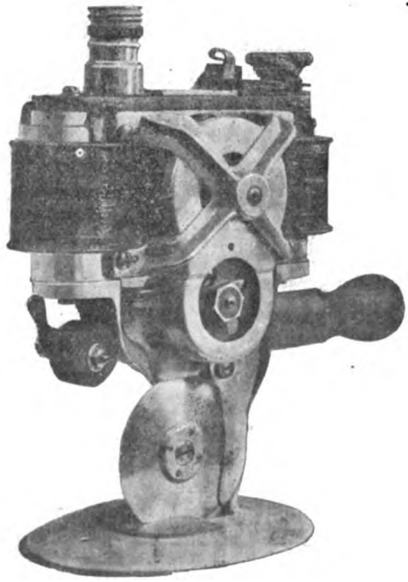
good deal of attention, and was conspicuous for its faultless action.

The Reason Manufacturing Company, Limited, Brighton, give a varied display of apparatus. Their "Lewis" arc lamps deserve special attention. Three varieties are exhibited—namely, the twin-carbon, the series, and the miniature types. All these lamps possess the great advantage of working without shunt coils, thus avoiding a fruitful source of trouble, and doing away with the cut-outs and substitutional resistances otherwise necessary. The electrolytic type of lighting meter is shown in actual working.



Humpage, Jacques and Pedersen's Combined Motor and Speed-Reducing Gear.

This meter is worked on the electroplating principle, and possesses a unique degree of accuracy and sensitiveness. The actual process of registration of the current can be easily followed by an inspection of this exhibit. Fuse boxes in great variety are also exhibited. The special advantage of these boxes is that they are so constructed as to render it impossible for a careless workman to effect a short-circuit when attending to a consumer's fuse. Reed's Electrical Engineering and Supply Company exhibit all kinds of electrical accessories, motors, wire and cable, etc.; and in conjunction with this firm Mr. W. Ruddock shows an electric cutter, of which we give an illustration. It is operated by a continuous direct current.



Ruddock's Electrical Cutter.

It is connected to the wires by a small flexible cable, suspended from a trolley wire fixed to the ceiling, and is so kept out of the way of the operator, but permits the machine to be used on any table in any part of the cutting-room. The motor drives the 4in. circular knife at a high speed, and the lines of any pattern may be accurately followed. The goods remain stationary, and the machine slides easily over the table and through the work. The current can be supplied from an ordinary light circuit, and the moment the operator turns off the switch, which is fixed on the machine, the expense for power stops. Another device by the same exhibitor is the "electric transmitter," which executes 4,000 stitches a minute. Its great features are absence of shafting, under drivers, and transmission belts, its immunity from oil drippings, smell, and dirt, and simplicity of operation.

The Electric Construction Company, Limited, London and Wolverhampton, show a motor of the well-known "Midland" type driving an improved "Expert" chain-morticing machine. Other motors and a rotary converter are included in their exhibit, and to illustrate the manner in which electric motors lend themselves to driving small tools, a portable drill, fitted on wheels, is shown. This arrangement enables the whole apparatus to be moved about without trouble, so that large or cumbersome work can be drilled without being moved from tool to tool. Messrs. Marryat and Place show a complete range of all the smaller sizes of M.P. motors from ½ h.p. up to 15 h.p., a number of motor starters, an electric furnace in which a temperature up to 3,700deg. C. can be obtained, automatic cut-outs, and also some iron-clad switches, in which class of work the firm claim to be pioneers. Messrs. Nalder Bros. and Thompson, Limited, makers of the N.C.S. electrical measuring instruments, have a representative display of such apparatus. Portable combined testing sets screened so as to be unaffected by external magnetic fields, recording instruments for current and E.M.F., illuminated dial instruments, an improved horse-power gauge for motor circuits, and automatic switches for charging accumulators are all to be seen at their stall.

In another hall the Electromotor and Dynamo Company present an extensive display of their machinery, which constitutes an admirable collection of such plant. The Brookie-Pell Arc Lamp, Limited, have a large display of their lamps—open, enclosed, and twin-carbon types—and a special feature is the patent contact gear for balancing suspended lamps at the desired altitude. An elegant exhibit is that of the Simplex Steel Conduit Company, Limited. It consists of showcases and boards mounted with samples, arranged on a framework made up of the conduits and fittings of the company's manufacture, with roof and polished boards at the back, on which are mounted the various fittings and accessories showing their application. On the boards and ceiling are displayed a number of lamps which are connected up by means of ceiling rose boxes, pendant boxes, lampholder fittings, brackets, etc., the distribution being from the six-way fuseboard, mounted on the back in the centre, the whole being connected to the supply and illuminated at night. This arrangement illustrates how, with a complete system of this kind, the whole of an insulation may be readily tested and inspected throughout by the removal of an inspection cover. Numerous samples of their specialities in wires and cables are to be seen at the stall of Messrs. W. T. Glover and Co. The remaining exhibits comprise those of the Lister Electric Manufacturing Company, of Dursley (London agents—Messrs. Pinching and Walton, 52, Cannon-street, E.C.); Messrs. Matthews and Yates, Limited, whose products include a refuse-collecting apparatus for use in sawmills and cabinet works; Messrs. Robinson and Co., Kettering, who are showing their triple-arm boot repairing and finishing machine; the Boxmaking Machinery and Engineering Company, of Turnmill-street, Clerkenwell-road, who show a number of their appliances for industrial purposes; the Electric Welding Company; Messrs. J. Sagar and Co., Limited; the Linotype Company, who show their composing machine and special arrangement for driving same; the Phœnix Dynamo Manufacturing Company, Limited, Bradford; Messrs. F. W. Potter, who, among other things, exhibit a 9ft. electric fan; and Messrs. Royce, Limited, of Hulme, Manchester, who have a good display of motors and dynamos.

If the number of novelties is not conspicuous, there are many engaging features, and the exhibition bids fair to quicken interest in the employment of electricity amongst the community. For the delectation of visitors the celebrated band of the 3rd City of London Rifles performs selections each evening, and sweet music is also discoursed by Messrs. Elman Bros. and Co.'s electric piano.

DESCRIPTION OF THE ELECTRICAL EQUIPMENT OF AN ENGINE WORKS AND SHIPYARD, WITH NOTES THEREON.*

BY H. O. WRAITH, ASSOC.MEMBER.

The author proposes to deal, as far as in his power lies and in the short time at disposal, with the question of converting large works of shipbuilding, engineering, or ironworks type to electric driving, and where, as a rule, outlay is a very great consideration, and the rulling question rather is "How can I get a maximum saving or profit in pounds, shillings, and pence for a minimum of outlay?" rather than "What is the most perfect method and apparatus to perform the work I have to do?" Corporations, as an example, and other bodies who can get the command of large sums of capital without trouble, do not hesitate to any great extent, and rightly so, to lay out capital in the most complete and, one might almost say, lavish electrical installations, so as to obtain the utmost maximum of efficiency of working; in some cases, indeed, the refinements of efficiency do not justify the outlay of capital. However, if people did not spend money in what are really experiments we should not be as wise as we are. But the class of place the author rather has in his mind to-night is very different. There, an enterprising member of a contracting firm goes to the executive of the ironworks, or whatever the case in point may be, and, after due preliminaries, says: "Look here, we will convert your works to electric driving for £20,000, and your saving will be £3,000 a year." The executive says: "That's an awful lot of money to spend; we haven't got and can't raise so much. Besides, I don't know anything about this electricity, and I must be certain that your figures are correct." After a year or two the executive decides to convert a portion of the works to electric driving as an experiment, spends £4,000 on it, is pleased with the results if the work has been properly designed and carried out, and finally converts the whole of the works.

The author proposes to take as a groundwork a fairly large electrical installation in a shipyard and marine engine works on the North-East Coast with which he has had the pleasure of being very closely associated, to give a short description of it, and comment on various points raised. Thus, even if there is nothing new about the installation, he hopes that room for discussion will be opened up, and that, at any rate, he will be able to learn something from the discussion. This particular installation is, as you will probably agree, rather a good example of those which have been built up in sections, without having foreseen and provided for the possible magnitude of the installation when laying down the first portion of the plant, and shows defects, but it teaches useful lessons by the very reason of its defects.

Description of Works.—The works premises consisted of (1) a marine engine and boiler building shop, about 240ft. long by 170ft. wide, divided lengthwise into four bays—viz., a small machine shop for the smaller machine tools, store, and fitters' gallery above, in the north bay; a bay for erecting the marine engines, and containing the larger machine tools, shaft lathes, vertical planers, etc.; a bay for building marine boilers; and a fourth bay for blacksmiths. On the south side of the engine works was a boiler yard, where funnels, smoke-boxes, etc., were built, and at the south-west corner of the boiler yard was the pattern shop. The power-house was situated on the south side of the engine works, and at its west end, at the top of a steep embankment. (2) East of the engine works was the shipyard, containing three berths, and all the scattered machinery and stock natural to a shipyard. At the west side of the yard was a joiners' shop and sawmill, containing a large saw for cutting up logs, and other machinery. (3) At the extreme east of the shipyard was the fitting-out quay, where ships, after being launched, were brought to have their machinery put on board and to be finished off ready for going to sea. On it stood a building about 85ft. by 35ft. wide, containing a fitting and blacksmiths' shop, a plumbers' shop, riggers' and shipwrights' stores, etc. On the quay there was also a steam-driven 100-ton jib crane, used for lifting machinery and boilers on board ships lying at the quay. (4) There was also, north of the engine works and west of the shipyard, the general offices, a building about 90ft. square and containing two floors. Between the offices and the engine works was the brassfoundry, a building about 80ft. by 70ft., containing the brassfoundry and a brass-finishers' machine and fitting shop, stores, etc. The installation of electricity was begun 10 or 12 years ago in the engine works, when a compound-wound dynamo of about 22 kw. at 110 volts output was put down to run off the shop shafting and drive two overhead cranes—one, a 30-ton crane, in the boiler shop, of the three-motor type, and one, also a 30-ton crane, in the erecting shop, of the single-motor type, driving the different motions by belts run off a common countershaft with fast and loose pulleys. The other cranes—a 10-ton and a 30-ton, in the erecting shop, and a 10-ton and a 40-ton, in the boiler shop—were driven by a square shaft running the whole length of each shop. The next addition to the electrical installation was when the present offices were built. They were lighted electrically at 100 volts by a secondary battery, charged by a dynamo driven from a gas-engine and placed in a room under the joiners' shop, which adjoined the offices. Shortly after this the subject of electric driving, which had often been mooted, was once more seriously discussed, and it was decided to convert the engine works to electric driving, as the shops were underpowered. Plans were made and the work was put in hand. A power-house was formed by building a retaining wall at the embankment on the north-east of the engine works and extending the old engine-house, which was at the top of the bank, towards the east, forming a building about 60ft. long by 53ft. wide. In it were laid down two direct-coupled, 220-volt, continuous-current, compound-wound generators and triple-expansion enclosed engines, each of 168 kw. output at 380 revolutions per minute. These two were placed in the middle of the floor space, and room was left for another set of the same size on each side of the two sets, which sets were afterwards added. The distance of the engines from the boilers was about 100ft., the main steam-pipes being led inside the wall of the engine works. A surface condenser of 1,200 square feet of tube surface, with steam-driven Edwards air-pump and circulating pump, was laid down, and a Klein water-cooling tower to deal with 12,000lb. of water per hour was erected outside the power-house on the south side. The main switchboard had three panels (one spare), with an automatic overload cut-out for the generator, main dynamo switch, ammeter, voltmeter, and equalising switch on each panel, while a main pair of 'bus bars, off which the circuit switches were taken, ran right across the board. A three-ton overhead hand traveller, running the length of the power-house, was put up. Steam was supplied at 160lb. working pressure from two multitubular marine type boilers, with about 1,350 square feet of heating surface, and fitted with mechanical stokers and feed-water filters. The arrangements for feed-water heating were crude, consisting merely of leading the exhaust steam from two horizontal Tangye pumps, used for supplying the hydraulic accumulator, into the storage tank for the softened water. The water softener itself was of the Archbutt-Deeley type, capable of dealing with 600 gallons per hour. The work done by the 110-volt plant before mentioned was, of course, put on to the central-station plant, the motors on the cranes being converted to 220 volts.

Distribution and Wiring—The distribution throughout was on the two-wire system. Both power and lighting circuits were taken off the same pair of 'bus bars on the main switchboard, to distribution boards in various parts of the works, from which sub circuits were taken to motors and lights. In some cases motors and lights were kept on separate circuits, the distribution boards for motors consisting of a pair of 'bus bars on slate with double-pole fuses for the main feeders and a double-pole fuse to each sub-circuit. The lighting boards had arc lamp switches and main incandescent circuit switches, as well as double-pole fuses to each sub-circuit and to the main feeders. In the case of isolated buildings—viz., the pattern shop, quay shop, brassfoundry, and shipyard blacksmiths' shop—

* Paper read before the Leeds Local Section of the Institution of Electrical Engineers.

Digitized by Google

the same distribution board was used for both power and lights, with one pair of main feeders, and although there was considerable relative fluctuation of the motor load in these places, there was no flickering of arc lamps sufficient to cause appreciable difference in the lighting of the place. Probably, if the generators had been shunt wound, flickering of lights would have been more noticeable, but even then it is so slight as not to justify the extra expense of installing separate mains for lights and motors. All conductors, whether main feeders or sub-circuits, were insulated, as a rule, with insulation graded at 600 megohms insulation resistance, for the reason that it is impossible to handle and dangerous to work near to bare conductors, and "aerial" conductors are dangerous from their apparent safety and the ease with which their slight insulation disappears in patches. A very good instance of the advisability of insulating main feeders occurred in 1901, when a disastrous fire gutted most of the engine works. All the cables to the shipyard (12 in all, of which the heaviest pair were $^{61}/_{12}$) were run along the engine works roof before the fire, and, to allow of rebuilding, were moved after the fire on to temporary poles across the boiler yard. In view of the work necessitated (which could only be done at week-ends, when the shipyard was shut down) in getting these cables back on to the roof, and their inconvenience when there, it was decided to lay them underground in the boiler yard. A cast-iron trough was laid, the cables were placed in it, and filled in with bitumen while they were alive—a job which could not have been accomplished with aerial or bare conductors without stopping the shipyard and causing very serious loss. In engineering works, where it essential that work should be carried on uninterruptedly, it is important that a system of wiring, such as the distribution board system, on which any section or sub-section of the electrical apparatus can be easily isolated, should always be adopted. Joints in main wiring should not be made, if possible. If they are inevitable, double-pole fuses should always be inserted at the joint. Earths on the system, if neglected, raise the repair cost bill very much, to say nothing of loss by stoppage due to breakdown; and it is important that as soon as a fault comes on it should be located at once, and the first possible opportunity taken to isolate and put right the faulty section. This is a much easier matter where it is only a matter of drawing fuses to isolate any portion of a circuit. It might have been advisable to have wired the lights on 220 volts with a middle wire—*i.e*, 440 volts between the outers—but the author thinks it is very doubtful, as arrangements would have to be made for balancing, and the cost of this in an installation of this size would probably have more than outbalanced the saving in copper. In addition to this, the load, when the first installation in the engine works was laid down, was carried by one dynamo, so that the three-wire system was impracticable, and later, when two or more dynamos were required, the advantage of the higher voltage across the outers was of no avail, as the heavier cables required for the 220-volt two-wire system were already installed.

Type of Engines for Generating Plant.—The choice of motive power for generating current depends largely on local circumstances—the price of coal, water, etc. Where water power sufficient is available, it is the least costly in running expenses, but as water power is so infrequent in this country, it need not be discussed. Gas and oil driving seem to be coming more or less into use, but, except in the case of works with blast-furnace plant, where an enormous power, which would otherwise go to waste, is at hand, or where the output is big enough to justify a special gas plant of the Mond type, probably does not successfully compete with steam. Where steam is used, the high-speed direct-coupled enclosed engine takes a lot of beating. If coal is very dear, and the load on the plant very variable, it may be advisable to put in slow-speed engines, with Corliss or similar valve gear, so that every possible ounce of steam may be saved up. But the capital cost of a slow-speed engine is very much greater than that of a high-speed one, and it takes up much more room, which considerations may outweigh any increased economy. It is a mistake to think, as some people do, that a high-speed enclosed forced-lubrication engine requires an inordinate amount of attention, or that it is beyond the power of an engineman who has been accustomed all his life to the old slow-speed D-valve engine to manage it satisfactorily. It is extremely simple, and if care is taken to see that the oil is kept right as to quantity, that it is drained of water, and changed and filtered at required intervals, it requires very little attention beyond taking off the doors occasionally to see that nothing is coming loose, and a thorough inspection, say, every six months or year. It will run all right with very much less attention than a slow-speed engine with complicated valve gear. The author has had no actual experience of steam-turbine driving for large generators, but is inclined to think that there is very little to choose between them and reciprocating engines, the balance, if anything, being in favour of the reciprocating engines. The steam efficiency of turbines seems, as a general rule, to be slightly less than that of well-designed reciprocating engines, though this is a question which seems to have been lately well thrashed out in the columns of technical papers. In selecting a suitable size of unit to adopt for an installation, first of all, the loads for all portions of the day and night, for power and lights, should be calculated out. In doing so it must be remembered that in altering driving arrangements it is possible, in the majority of cases, to speed up tools of all kinds and increase their output; this adds to the power required to drive them. The size of the unit should be based on the minimum regular load required, and should be, if possible, such that, whatever the load is, the generating plant, or such portion of it as is running, is running as near to full load as possible. A spare generating set, over and above the plant required for the maximum load, should be laid down. No hard-and-fast rule can be laid down for the size of the generating units, but it is generally possible to manage so that the number of units running at full load can be altered to suit the work's requirements, without making their size too small for good efficiency, and yet the cost of the stand-by plant is not unreasonably great.

Main Switchboards.—The type of main switchboard built and supplied by the leading manufacturers for installations such as that in the works under discussion, is so well known that it seems rather unnecessary to mention them. There is no doubt that the small panel system, by reason of the easiness of extending the board, ought to be used. The generator panels should be fitted with main dynamo switches and fuses, automatic overload circuit breaker, ammeter, voltmeter, recording meter, and the necessary paralleling switches for each dynamo. The dynamos feed on to a pair of main 'bus bars, off which the circuits are tapped. The circuit panels should have double-pole switches and fuses for each circuit, with preferably an ammeter in each circuit. The author does not think that overload circuit breakers are necessary on every circuit, and where it is advisable to introduce them in the circuit—as, for instance, in crane circuits where there are bare trolley wires liable to be short-circuited—it is probably best to put them in the shops where the circuits are doing their work, so that in the case of a short-circuit occurring, the switchboard attendant does not try to switch them in circuit again, and so, perhaps, bring out the dynamo circuit breaker. A very necessary fitting on a switchboard is an earth lamp with a two-way switch connected on to the 'bus bars. It can then be seen at once whether any earths exist, a thing that is not always bothered about if someone has to take the trouble to rig up a lamp with a couple of wires and test at intervals.

Motors.—The motors in the engine works and shipyard used for driving the constantly running machinery were all shunt wound and of the enclosed or semi-enclosed type. The sizes varied from 6 h.p. to 40 h.p., and the standard sizes adopted were 6, 10, 15, 20, and 40 h.p. Wherever possible, any new motors put in were of these standard sizes, so as to keep spare parts to a minimum and inter changeable. The motors on three-motor cranes, and where driving single reversible machines direct, such as plate rolls, were series wound. The total rated horse-power of the motors in the engine works, brassfoundry, and pattern shop was 476, the total in the shipyard being 568. In the engine works, machine and boiler shops, except in the cases of the large machines, such as the big vertical planers,

Digitized by Google

plate-edge planers, and boring-mill, etc., all the tools were driven off lines of shafting by a single motor. In the case of the large lathes for turning propeller shafts, the conversion of which took place before the author's arrival on the scene, this was probably a mistake. In the extensions of the engine works, now taking place, all the big lathes will be direct driven by separate motors with speed regulation. At the time of the installation of electric power, large use was made of drills and chipping tools driven by compressed air, and the author experimented with portable hand electric drills for the purpose of comparing them with the pneumatic in weight for power, cost, and efficiency. The conclusion he arrived at was that for holes up to about $\frac{3}{8}$in. to $\frac{1}{2}$in. in cast iron, the electric drill was superior to the pneumatic in first cost, cost of running, efficiency, and weight for power given. For holes above that size, the first cost of the electric drill gets much greater than that of the pneumatic, its efficiency is much higher, and its weight for power becomes prohibitive in a crowded shop or where the drill has to be moved about much. It may be interesting to give a few figures, from tests taken, as to the power absorbed by tools, etc. (see Tables A, B, and C).

TABLE A.—Turning Wrought-Iron Propeller Shaft.

Tool.	Lbs. of metal removed per hour.	Cutting speed, feet per minute.	Cut.	Traverse.	Net B.H.P.	Lbs. of metal per B.H.P. per hour.

F ...	$\frac{3}{32}$in.	13·5	—	45 about	—	—	Tool very blunt

These figures were taken on the ordinary work done by the planer. The tool was of ordinary tool steel, and it was worked with feed and speed at which it would remain fairly sharp for about an hour. It will be seen from the reading F what a very great difference a blunt tool will make, this tool being one that had been taken out for regrinding. As will be seen, it was useless for anything like a heavy cut, the motor fuses blowing at once. These figures are, perhaps, not of much value as far as the powers required for any individual machines are concerned, but they are useful to form a rough estimate of the power required for groups of tools, which is a different thing. The starting currents for Nos 12, 13, 14, were taken to show the heavy torque required to start the class of machinery with heavy moving parts, such as that used in a shipyard. The usual average of time taken to bring these machines from rest to full speed would be 20 to 30 seconds, and in all three cases it will be seen that the peak of the current taken at starting was considerably over the rated full-load current for the motors, although, looking at the other figures, one migth think that smaller motors could be safely used. As the speed of these machines need not be very constant, and to help at starting, it is better to have a few turns of series winding on the motor field coils. The author thinks it advisable, as machinery of this class is, as a rule, scattered, intermittently used, and generally started and stopped by any man who may want to punch a hole in a plate, and knows nothing about electricity or electric driving, to keep well on the liberal size when selecting sizes of motors, so that rough usage is less liable to cause breakdowns. Three or four hours' stoppage of a single punching machine at a busy time may cause more loss than the loss in a year due to the less efficient running of a motor larger than is absolutely necessary. Wherever several machines were grouped within a short distance of one another, the plan was adopted of placing the double-pole switches and starters for the motors of the group in a cabin at a point visible from all the machines, and putting a boy to do all the starting and stopping of the machines in the group at signals from men going to use the machines. In all cases of driving separate punching and shearing tools belt drives were employed in preference to spur or chain gear. When starting a heavy torque is required, and a belt allows of a certain amount of slip till the machine has got up speed, and relieves the motor of some of the strain it would have were it rigidly connected to the gear. Also, in the case of punching the motor has very little to do with the actual punching. It gives the moving parts their inertia, and this inertia carries the punch through. Even during the quarter second or so taken by the punch to travel through the metal, the speed of the machine is affected, and here again a belt drive is advantageous, for the belt will slip, and reduce the momentary load thrown on the motor, where rigid gear would give it a big shock, to say nothing of the risk of breaking teeth on gear wheels, a much more serious matter than a broken belt. The author has seen a heavy 4ft. cast-iron spur wheel, with teeth about 1½in. thick at the root, and 6in. wide, with very heavy arms, rim, and hub, smashed in four or five pieces on one of these machines in shearing an angle bar, while the belt, although without guides, did not even come off the motor pulley and flywheel. In the case of shearing machines, the working stroke—*i.e.*, the period when the blade is actually cutting through metal—lasts for a much longer proportion

TABLE C.—SCHEDULE OF WORK DONE BY MOTORS AND POWER ABSORBED BY THEM.

No.	Machinery driven by motor.	Max. starting current.	Min. B.H.P.	Max. B.H.P.	Normal working B.H.P.	B.H.P. absorbed in shafting.	Remarks.

of the total stroke, but the conditions are very similar, and the belt drive gives elasticity which cannot be got by direct spur driving. The stroke of a shear blade is less of a blow and more gradual than in the case of a punch, and lasts long enough to appreciably overcome the inertia of the moving parts, the motor thus having a harder job than when punching.

(To be continued.)

SIMULTANEOUS TELEGRAPHY AND TELEPHONY.*

BY JOSEPH HOLLOS.

The question of simultaneous telegraphy and telephony is not of recent date. While, however, in some places good results have been obtained, in others the advantages reached by this combined using of telephonic circuits are hardly worth mentioning, and in view of the difficulties experienced in the service it was thought better to abandon the scheme.

If we look closer at the question, we can at once observe that wherever the telegraph and telephone services are under the supervision of one and the same interested person the results obtained are excellent. Where, however, the two systems are in different hands the result is unsatisfactory. Thus, in America, where the financial interest of the telephone companies is involved, because of the desire to increase income by leasing lines for simultaneous telegraph, and where, for this reason, these two operations are under the control of one technical staff, the result is excellent. The results are also fair in the European services, if the same technical officer supervises both telegraphy and telephony, and one service is co-ordinated with the other. The result is, on the contrary, very poor in all cases if the telegraph and the telephone services are in different hands.

This is evident if we consider how greatly the one system interferes with the other—that is, that careless handling of the one interferes at once with the proper functioning of the other—the two systems thus being brought into mutual opposition. For this reason the service must be arranged in such a manner that the two systems cannot interfere with each other, and in as far as troubles are unavoidable, they must be reduced to a minimum. If they should exceed, certain arrangements must be provided to hold out the less important service without delay.

In this direction the Hungarian telegraph and telephone service can show good results by comparison with similar installations, and, therefore, it will not be without interest to outline the principles which were followed in the formation of the system. Above all, the simultaneous installation must be the simplest possible, because only thus and with the fewest possible instruments may undisturbed working be obtained. For this reason the method of simultaneous working founded on the Wheatstone bridge principle, was made the basis of procedure.

The telephone circuit is closed through two inductive branches. At their point of intersection the battery branch is led off to the group of telegraph apparatus, while the telephone apparatus is placed in the so-called galvanometer branch. It is thus evident that the connecting-in of the telephone apparatus—namely, the leading of the telephone circuit through the switchboard—requires some care, because if there is a ground in the switchboard connections the telegraph working is disturbed. Even if one telephone circuit is directly connected to another, and there be simultaneous working on the latter, the two telegraph simultaneous systems are brought into contact, which again causes marked disturbance. This may also be caused by the operators ringing simultaneously on several circuits from the same common source of ringing current.

Even if only one of the circuits fed from the common ringing source is connected for simultaneous telegraphy, such working will still be slow, because in ringing on the simultaneous conductor we ring also on five or six other conductors. However well insulated these circuits may be individually, the insulation of the simultaneous telegraph circuit will be so far reduced by the connection that it will hardly be possible to maintain continuous telegraph working.

It is true that we can remove all these difficulties at one stroke by connecting the incoming telephone circuit, before leading it to the switchboard, to a repeating coil, and working then only on the other half of the repeating coil. But by this plan the difficulty is only transferred to the other side—the telephone side. Above all, we have a loss of energy in the repeating coil, to which are added losses inevitably occurring in the signalling apparatus, and it may happen that with such an arrangement the telephone subscriber does not get as much as 50 per cent. of the incoming speaking energy into his receiver. We must strive, therefore, that along with the undisturbed working of the telegraph, the telephone working be kept at the same relative level that would exist in the absence of simultaneous working. Moreover, the repeating coil not only weakens the speaking current but also the calling current, and we must, therefore, take precautions in this direction.

Under these conditions it is inadvisable to connect the circuit first to the repeating coil. As long as the circuit is on the calling apparatus there is no danger of disturbing the simultaneous working. The disturbance arises only at the moment of connecting. For this reason it would be sufficient to place the repeating coil in the connecting cord; but in the same path there is also the clearing-out signal, and a great loss of energy might thus be incurred. This we may, however, remedy if the repeating coil is constructed in such a manner as to serve at the same time as the clearing-out signal.

The clearing-out signal is, as a rule, connected in the bridge between the two branches of the circuit, and its duty is by its great self-induction to prevent the wasting of any considerable part of the speaking current. How far it is able to satisfy this demand might be readily ascertained by inserting a receiver in the shunt path. In spite of thus increasing the impedance of the bridge we still obtain intelligible speaking even with a clearing-out signal of 2,000 ohms resistance, if the latter is entirely embedded in iron. These currents do not so rigidly follow the rules which apply to strong currents, and therefore inferences drawn from such rules do not apply in this case, as may be shown by a simple experiment. With such a clearing-out indicator, 30 per cent. of the energy is lost on the average, and 70 per cent. only is available, as I have been able to ascertain myself.

With a well-constructed repeating coil, if arranged as a clearing-out signal, the loss is not greater. Consequently, if we insert such a repeating coil into the connecting cord, simultaneous working without affecting the telephone is secured. The repeating coil transformed into a clearing-out drop naturally possesses a closed iron circuit. In European practice this plan is avoided, and an open-circuit repeating coil is generally preferred. The question whether the repeating coil has an open or closed magnetic circuit does not affect the high frequency involved, and for weak currents this is of much less importance than the other losses that arise in an open-circuit repeating coil. For relatively strong signalling currents the closed iron circuit is of decided advantage, because, with open-circuit repeating coils, it is only exceptionally possible to ring through with alternating current, while it is always certain when there is a closed iron circuit.

From the point of view of simultaneous working it only remains to separate the ringing currents. This may be accomplished if alternators are used by branching the ringing current at each operator's position on a separate repeating coil. Where batteries are used, which are to-day exceptional, each operator's position must be given its separate battery.

In the simultaneous working apparatus itself the branching coil is of the highest importance. It is most important that the inductance on the two sides should be equal. This is more important than the exact equality of their ohmic resistance. This, however, determines not only the resistance of the coil, but also the size of copper wire to be used.

From the point of view of choking, it is desirable to use long coils; such coils, however, by reason of the phenomena of dispersion, prevent the complete neutralisation of the telegraph currents, and, therefore, it is necessary to select short coils. With such an arrangement the operation of

* A paper presented before Section G of the International Electrical Congress of St. Louis.

the telegraph apparatus is not perceptible on well-balanced telephone circuits.

GLASGOW'S NEW TRAMWAY MANAGER.

The mantle of Mr. John Young has fallen upon Mr. James Dalrymple, who during the last three years has fulfilled the office of deputy manager. Mr. Dalrymple has served in various departments of the Corporation for 23 years, and has been associated with the tramways since 1894. As accountant he was entrusted with the management of the tramway finances, and, like Mr. Young, he entertains strong opinions on the subject of depreciation. He has devoted considerable attention to the subject of tramway economics, and was invited to present his views before the Royal Commission on Municipal Trading.

MR. JAMES DALRYMPLE.

In 1901 Mr. Dalrymple was appointed deputy manager, and the Convener of the Tramways Committee, in recommending him for the managership at the meeting of the Corporation last week, stated that the committee had no hesitation in selecting such a tried official for the important position hitherto held by Mr. Young.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

XI.—On Mixing with the Men.

My Dear Young 'Un,—I am sorry to hear that you went to Jack Blogson's benefit last week. Who Jack Blogson may be I have not the remotest idea. I am fully prepared to hear that he was a hard-working turner who got himself tied up in the back gear of his lathe and has been out of employment for 18 weeks; that he has six children and a small wife who takes in washing—this being their only means of subsistence. Yet, while offering every sympathy to the man (and if you had a direct subscription list I wouldn't mind putting my name down if the affair struck me as worth it), yet I would point out to you that this benefit was, as you admit, held in a low pub, that quantities of beer were drunk, that some of the songs were high—almost decomposed, in fact—and that you had a fearful time getting the foreman home. Now, who got the benefit of that orgy? *You* didn't, because you wasted an evening and got a fat head. Jack Blogson didn't, because he got blind drunk, and his small wife had to come and steer him home. The man who got the benefit was "the gent wot howns the 'otel!" And I may tell you this: you have lost caste with the men. They may call you a jolly good fellow, and hit you on the back, if that is any use to you, but down in their own minds they have lost that respect for you as a man who has sterner ambitions than their own. You have now got a couple of months' leeway to make up.

This question of mixing with the men is a most difficult one—particularly at your stage. Later on, when you have got some practical knowledge of your own to go on, the difficulty will vanish. But at present you have all your shop experience to learn, and the men who will teach you—or "take the twist" out of you, as the case may be—are the fitters and turners around you; you must therefore keep in touch with them. At the same time, if you clog yourself with their mire you will incapacitate yourself from rising. More than once I have seen a smart young fellow barred from a position of trust because he was too hail-fellow-well-met with the men for whom a foreman was wanted. You must hold yourself in reserve a little. Remember that the operatives about you have got on to the flat of their curve, while you are still on the upward slope. Although, judging by shop standards, your ordinate may at present be shorter than that of the fitter next to you, yet your maximum is going to be a lot bigger than this, and he won't forget it if you don't.

I am of opinion that this mixing with the men is the cause of the shoal of mediocre engineers we have about at present. It isn't the fault of the colleges or shop systems; it is the fault of the students. A man comes from college with a consciousness that he is in for an entirely new set of experiences. Young and not altogether self-reliant, he hastens to make friends-of-convenience of the men he is working with. This is usually done by "paying his footing," which consists in handing away sums of money to the nearest bar-keeper to lubricate the throats of comparative strangers. This species of blackmail is all the more galling because etiquette demands that it must be performed with an appearance of extreme gaiety and good-fellowship which is not really felt by either party, because at that stage neither knows the other.

The wheels of life having been thus lubricated, the workmen will now try to sell tools to the novice, disposing of their old and worn-out stock; and their further estimation of his character will depend upon the combination of acumen and affability which he displays. In any case he will probably be had, but the all-important object of making acquaintances will now have been achieved.

And when this is done, what is gained?

Why, the man next to him will mark his approval of the newcomer by saying he knows a chap who does a little book-making in a quiet way, and who has just given him a sure tip for the Doncaster. Would the newcomer like to put anything on it?

If the newcomer is a wise man he will give a decisive and ornamental *NO*, because that is just where he is going to spoil himself. Beer-guzzling and horse-racing are the two biggest vices of the British workman, and these vices won't run in parallel with study for a month. If you start these capers in order to please your workmates, you are just taking the short cut into the ditch. Better plod along on the main road of hard study and initial unpopularity. Your reward will come later.

In talking on this subject, however, I must let you see the other side. It is no good being a snob or a recluse. You are going to do yourself almost as much harm that way as the other. The man that I always wanted to grind up against the wall and push about the dirty floor, when I was in the shops, was a haw-de-haw youth who was always reminding everybody that his father was the principal shareholder, and that he himself was on his way to the assistant manager's chair *vid* the drawing office. Inexplicable accidents were always happening to that young man, and the number of times the fellows had to beg his pardon for inadvertently putting their gear wheels and other impediments where he was bound to trip over them was incredible. He came to a bad end. He committed the blazing indiscretion of bringing his best girl round the shops one day, and then the band played! While he was explaining what the belt was for on a lathe, and while he was describing the process of case-hardening, there was a gentle whistling chorus of "Here we come gathering nuts in May!" Nobody was doing it—everybody hard at work! But everyone was looking pleased except the foreman, who had been tipped. The girl couldn't stand it; she fled incontinently, and our young duke followed. There was an office enquiry of the largest dimensions, but as nobody had done it, nobody was nabbed. But the dukeling never came back.—Yours,

The Old 'Un.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

THE METRIC SYSTEM.

The agitation in favour of the metric system, as might have been expected, has commenced directly the vacation was over. The Rugby Engineering Company has the matter under discussion. It will be seen from the report, given in another column, that opinions are somewhat divided. The result of the discussion, for or against, will be known at the adjourned meeting next week. It is fortunate that just at this juncture the opponents of the system have entered the field. As the late Sir Frederick Bramwell so aptly remarked, there is always a danger in this country of having an objectionable new departure more or less forced upon us because its advocates are sincere and active, while its opponents, being satisfied with what already exists, do not make their opinions and power felt. Such is the case with regard to the metric system. Its advocates are persistent in their efforts to force it upon an unwilling population; and as the opponents have hitherto not acted in combination, very little weight has been given to the opposition. We do not pretend for a moment to suggest that the advocates of the metric system are not sincere; they are, and it is owing to this intense sincerity that troubles may arise. The text of the advocates of the metric system is fairly summed up Mr. Briggs, the advocate of the system before the Rugby Engineering Society: "The most elementary question which naturally presents itself is, 'Why should we adopt the metric system?' Leaving aside the wider interpretation, the answer is, 'Because of the ever-increasing necessity for an international system of weights and measures.' Admitting of such necessity, the questioner next asks, 'Why should we change our system of weights and measures, instead of the Continental nations changing theirs?' to which we reply, 'Because the metric system of weights and measures is greatly superior to the Imperial system.' With the advocates of the metric system rests the *onus probandi*." We are not going to dwell on the advocacy side of the question—that can be read on another page. We are opponents, and welcome the formation of the British Weights and Measures Association, which has for its objects the defence, standardising, and simplifying of British weights and measures. The executive of this association consists absolutely of practical men, with not a single representative of academic learning amongst them. In this controversy it will not do to count heads. We have rather to estimate values, and, in our opinion, the views of such men as Denny, Kaye Gray, Musgrave, and Paxman outweigh the views of all the academies and schools in the kingdom. The gist of the small pamphlet just issued by the association may be summarised: "The persistent efforts of the advocates of the French metric system to get it enforced in the British Empire have brought into being the British Weights and Measures Association, whose primary object is to combat the metre. It also seeks to standardise and simplify British Imperial weights and measures, so as to make them in the greatest degree available for all purposes. There is a risk that the metric advocates will be successful if opposition is not organised, for the tendency is to let judgment go by default on account of the ignorance which prevails as to what the suggested reform really means to Britons. Believing that the enforcement of the metre in the British Empire would be a national calamity, we seek not only to organise those whose studies of the subject have enabled them to see the hollowness of the metric pretensions, but also to provide means of educating those who now directly support the metre by reason of their knowledge being limited to theoretical application, and of those by whose apathy the movement receives negative support, and who may possibly have never

Digitized by Google

had occasion to give the subject a thought, but who will be sufferers by it should it be enforced." It is pointed out that the system known as the metric system is but a fragment of what was originally intended, and even this fragment is not universally accepted in the nation of its birth. All those that go down to the sea in ships refuse to have anything to do with the metric system It is to them an impossible system. And if it cannot be applied on sea, its advocates suggest that there should be one system applied on land and the other on the water. Then again, the textile industry even in France will not accept the system. In the manufacture of cotton, woollen, worsted, linen, jute, and hemp the English system is practically universal. It is based on yards, inches, pounds, ounces, drams, and grains. The drastic laws that have been made in France to compel the use of the metric system have been but partially successful. The French hatting trade threatened with the infliction of the metric measures strongly objects. The English measurements of draught, displacement, and tonnage are universal. The metre is just as much an artificial unit as is the yard. The metre is too large a unit for engineering work, and the millimetre is too large for the finer work. Far better, according to these practical men, is the mil of one-thousandth part of an inch. The fact of it is the glamour of the metric system, when analysed, has nothing to do with the metric system itself, but simply depends on the decimal system. Again referring to the late Sir Frederick Bramwell, he was always caustically sarcastic when dealing with pure decimalists, maintaining that in an equal number of cases familiarity with vulgar fractions was just as useful as familiarity with decimals. One of the arguments put forward by the advocates of the metric system is that it has been adopted by this, that, and the other nation. Well, that is like the nonsense talked about American progress in certain directions. America was an open field, hence there was room for anything. So with those nations as regards metric or any system, open to anything that came along, and took the first thing that politics pressed upon them. Let us see what the opposing association says on this point, and we trust we shall hear little more of that particular phase of the argument: "When the metric advocates are beaten on all other points, they invariably fall back on the sentimental idea of having one language for weights and measures throughout the world. They point out that thirty-six out of thirty-nine civilised nations have already adopted the metric system, and it is only common justice that the minority—British Empire, United States, and Russian Empire—should give way to the majority. That looks very plausible, but what of the relative importance of those countries. Taking those thirty-six nations in order of population, none of the first four have the population of Liverpool. Lancashire has more inhabitants than any of the first eighteen. The total of the first twenty-four is only equal to the population of the United States. There is a larger population within fifty miles of Manchester Town Hall than in any one of the first twenty-five of those nations. The Russian Empire has a population equal to the first twenty-eight, and the British Empire alone has four million more people than the first thirty-four added together. Counting the three against the thirty-six we have 567 millions against 445,296,000, and the measures of those 567 millions are all based on the English inch. Looking at the question from the point of view of trade and commerce, the Anglo-Saxon race alone has the pre-eminence, which makes the vaunted position of metre users ridiculous." There is another point noticeable in many of these agitations: the advocates are either men of merely academic training or men directly engaged in competition with this country, hence desire to foist their own system—worse or better—thinking that any change plays into their hands.

THE TRUTH v. "THE JOURNAL OF GAS LIGHTING."

Our contemporary has evidently taken to heart our strictures of last week, and has done its best in reply. It makes certain that we shall see the reply, and so kindly sends a copy of its issue to this office. Many thanks for so doing, but as we have subscribed to the *Journal* for many years, the duplicate copy is wasted. We are glad of the further opportunity the *Journal* has given us to express our opinion as to its tactics. We have no word to say in its favour, no word to withdraw from what it terms our vulgar abuse; rather to add to what we have said, and in still stronger language to show the contemptible manner in which the *Journal* treats things electrical. It now admits that its usual method of dealing with electrical matters is to take second-hand statements, because "the original financial statements of electrical undertakings do not with great frequency get addressed to the office of the *Journal of Gas Lighting*." Our contemporary makes merry over slackness editorially, but does not see the gulf into which it has itself sunk. Here is a paper which every week for years past has sown broadcast statements culled from other papers without any editorial attempt to get information at first hand. We should have thought a paper taking up the position the *Journal* has taken would have made certain of its facts from original documents—which, by the way, it can as easily get as we can, at a small cost or a little trouble. Now, what is the policy of the *Journal* as regards electrical work? There is no doubt but it has for years set itself to damage the electrical industry, and to do this provides its readers weekly with electrical memoranda. These memoranda are consistently of the truthful character, but usually only half the tale is told, and to combat a half-truth satisfactorily is the most difficult operation. The selection of items, again, in this weekly trash is very peculiar. They are always of a character to lead the reader to decry electrical work, and never by any possible chance record much that is of a satisfactory nature. If this is not delving in dirty ditches, what is it? Our sapient contemporary is wise enough to try and twist our words to a meaning they do not bear. Our electrical contemporaries are *not* the dirty ditches. They record good, bad, and indifferent matters. They do not always agree with us. We do not expect it, and should not respect them if they did. But the *Journal* picks and chooses from this second-hand stuff, and picks only that which seems damaging. It makes its own dirty ditches, and does not find them already made. Take the *résumé* of the current number. It deals with the muddle at Dublin, a gentle rap over the knuckles at Southampton, Dartford and the Local Government Board, ourselves, and Wrexham. There is no redeeming feature, there is no good in anything electrical, so far as the *Journal* is concerned. To us it borders on the infamous that any so-called respectable journal should always flaunt in its columns what is thought damaging and never admit aught that is encouraging to an industry. It pretends that it did not see in the sentence we inserted—involved as it is acknowledged to be—that there must be an error. There could not be two deficits differing in amount. The fact is, our contemporary was only too eager to pounce upon figures that seemed to favour its methods of discussion, and did not expect to have to acknowledge its second-hand method of getting information. It is the champion of gas. Let it remain so, but if it presumes to give electrical information, let it be honest and

Digitized by Google

say it only gives the most damaging it can find in all the other papers, and carefully refrains from checking from original sources.

OBITUARY.

The late Desmond G. FitzGerald.

It is with exceedingly deep regret that we have to record the death of Desmond G. FitzGerald, who passed away at his residence at Clare, Suffolk, on Sunday last in his seventy-first year. In our estimation the late Mr. Desmond G. FitzGerald has never obtained the general recognition his ability and devoted work in the service of electrical science deserved. The son of the editor of the *Morning Post* in its palmiest days, he was in his youth familiar with the talent and the beauty of the early Victorian period; partly educated in France, he witnessed the scenes of '48, and undoubtedly his whole life was tinged with the teachings prevalent in the France of that period. He entered the War Office, but monotony and the routine of official life did not appeal to him, whose delight was scientific investigation, and especially in the domains of chemistry, electro-chemistry, and electricity, and his object was in the commercial application rather

THE LATE DESMOND G. FITZGERALD.

than the mere accumulation of facts. That he appreciated work in other directions will be agreed if we mention that he was one of the earliest inventors who endeavoured to perfect the breech-loading rifle. We believe it was in 1861 he resigned his position at the War Office in order to devote his whole attention to the production of a weekly paper devoted to electrical subjects, and thus the *Electrician* started. The task he undertook was Herculean, and although the paper was conducted with the greatest ability and energy, the time was not ripe for so big a venture, and after a few years it ceased to exist. Later on he assisted and for a time edited the *Electric Telegraph and Railway Review*, which also, after a short precarious existence, ceased to be published. A careful examination of these early papers cannot fail to prove to the most sceptical that it was from no lack of energy or ability or material that they failed, but that the public interested was not sufficiently large to guarantee success. Mr. FitzGerald also contributed largely to the *Engineer*, to the *English Mechanic*, and to other technical papers. To turn to another side of his labours, during the whole of his career Mr. FitzGerald was an assiduous experimentalist, and, if we dare venture to say so, failed but by a hair's breadth to become one of the greatest of British inventors. If the records of the Patent Office are searched, there will be found specifications relating to electro-chemical products, to telegraphic apparatus, and to secondary batteries, any of which, falling into the right commercial hands, might have created an industry. We in this brief notice can but indicate the inexhaustible energy of the man. During the greater part of these years he was not only writing, experimenting, and inventing, but he was teaching, and, indeed, was the principal teacher in the school of telegraphy which was opened in the sixties, and carried on during many years by Mr. Lundy, subsequently by his widow and Mr. Jones. A great majority of the men who entered the cable service in the sixties and seventies received a training under him. Turn we now from the work to the man. He was an original thinker and a capable teacher, while his command of the English language as a writer and a speaker was unique. This might not usually be gathered from casual observation, because of a hesitancy in his speech, but careful observation would show the listener or reader the elegancy of his diction—no word misplaced, no word misused, no word too many, and none too few.

> Then when the clay-cold form shall bid adieu,
> Hid in its parent's bosom, kindred earth,
> Let not the errors e'er appear in view,
> But turn from them and only speak his worth.

Nearly 30 years of intimate friendly intercourse with the late Mr. FitzGerald compel us to accentuate the view that his ability and attainments were of the highest order. His ideals were high, his hatred of anything mean intense; and if he failed to ingratiate himself with those with whom he was brought into contact, it was because his instincts were higher, nobler, truer, and finer than those of men who are buffeted about in the strenuous strife of the world He lived in a world of his own, which few understood, and fewer still cared to examine. Those of us who knew him well loved him for his merits, and our heartfelt sympathy goes out to his widow and daughter in this the time when their great loss is so vividly felt. At the last his cry was rest.

> And rest more sweet and still
> Than ever nightfall gave
> Our longing hearts shall fill
> In the world beyond the grave.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRICITY FROM WATER POWER.

SIR,—I regret to find that in my British Association paper on the above subject, published on p. 294 of your issue of Aug. 26, I erroneously attributed the list I gave of plants recently installed to the Stanley Electric Manufacturing Company, of Pittsfield, Massachusetts, instead of to the General Electric Company of America, as should have been the case.

I make this correction at the request of Mr. C. C. Chesney, the chief engineer of the Stanley Electric Manufacturing Company, from whom I originally obtained the particulars, and would explain that the mistake occurred through my interpreting the words "our later installations," used by Mr. Chesney in his communication to me, as meaning installations put up by his company, whereas I now hear from him that the word "our" in this connection referred merely to American installations as distinguished from those of other countries.—Yours, etc.,

A. A. CAMPBELL SWINTON.

TESTING BOILER FEED.

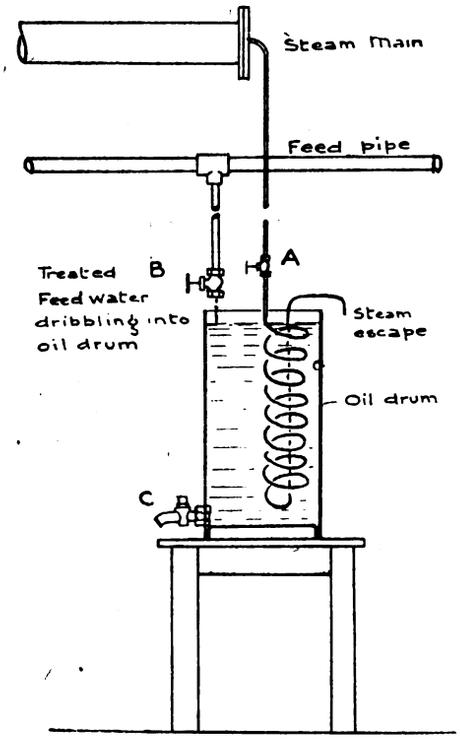
SIR,—I have read with interest the replies to Question No. 691, but rather fancy the propounder of question is not altogether satisfied with the replies, although they strictly answer his question. I would venture to state that what No. 691 wants to know is when he has got the right proportion of reagents in his boiler feed water, rather than to know the degrees of hardness. I have experienced considerable trouble myself with the same subject, and, with all due respect to the assistance given by many chemical friends, had never managed to get really satisfactory results until I adopted the method mentioned later on.

One of the main reasons, I think, for the failure of any chemical tests of the water to produce satisfactory results from an engineer's point of view, is that they fail to take into consideration that the evaporating of water in a

Digitized by Google

boiler is really a concentrating process. A very small increase or decrease in the exact chemical quantities of the lime or soda over that theoretically required will give trouble. In the first case it accumulates in the boiler when the water will become too alkaline and attack the iron, owing to electrolysis between it and the gunmetal fittings, or in the second case the excess of "untreated hardness," if I may use the term, accumulates and produces a hard scale on the boiler. Further, as a result of many tests made, and of some few years' experience, the degree of hardness of the water is in most cases nearly always changing, due to the action of rain diluting the stream from which the water is drawn, and from other obvious causes. So that the reagents required to properly soften the water during one week may be quite wrong during the next, and an engineer cannot always afford the time to constantly test the feed water for hardness, even if he could obtain satisfactory results by so doing.

Ultimately I schemed out the following plan, and may since its introduction have practically had no more trouble. The sketch will nearly explain itself. An ordinary 10-gallon oil-drum is placed upon a stand. Inside is a coil of ½in. iron steam-pipe, supplied from the nearest steam-main



through a cock, A. A branch from the feed-water delivery (say a 1in. pipe to prevent choking) with a valve, B, in it is led to the top of the drum, and the feed is allowed to dribble out into the drum. The action is as follows: the drum being filled with feed water, the steam is just turned on to the coil sufficiently to keep the water just boiling and the feed supply regulated to just make up the evaporation. Now, whatever is going to take place in the boiler itself will take place on the steam coil. If the water is not sufficiently softened a hard scale will form on the coil, or if there is too much alkalinity in the feed, the iron around the brass drain cock, C, will show black, or may be this blackness will not be noticed unless the scale (found, say, previously) be knocked off, for it is not uncommon, when too much soda is used, for the interior of a boiler to look scaled while really underneath the scale the iron is being pitted by electrolytic action.

A week or two of experimenting with the above apparatus will enable any engineer with a few brains to properly proportion the reagents required; and what is more, to instantly correct any tendency to scaling or corrosion. I have found the most satisfactory results in the boiler to obtain when the steam coil showed just a soft thin covering of whitey-brown mud that could easily be dislodged from the coil by a piece of pinewood. As to the action the different reagents have upon the boiler feed water, these are given fully by the replies from your correspondent, so that by reading them carefully and by using a little thought and care to see the reagents properly weighed and added, anyone should be able to get good results when using the apparatus described. I may add, in conclusion, that the lime used should be dried in an old copper or other pot, as, owing to the amount of moisture usually in air-slaked lime, there is considerable difficulty in getting accurate weights.—Yours, etc., A. W. TOURNAY-HINDE.

MOTOR STARTERS.

SIR,—With reference to an article appearing in your issue of Oct. 7, under the heading of "Notes on Motor-Starting Switches," we notice the writer finds fault with asbestos mandrils for supporting resistance coils. We cannot agree with his remarks, as our experience points to quite the reverse. Many makers have found porcelain supports unreliable on account of their friability, and this has led to our placing on the market a special form of "Arkite" tubing, which has been successfully used by many of our leading electrical manufacturing companies for supporting resistance coils for fuse carriers, for large currents, and generally for electrical purposes where great heat or arcing occurs.

We may mention that "Arkite" tubing has none of the defects usually found with resistance-coil supports, and we have pleasure in sending you a sample, which will amply bear out our statements.—Yours, etc.,

THE CAPE ASBESTOS COMPANY, LIMITED,

London, Oct. 12, 1904.

'E DON'T KNOW WHERE 'E ARE!—OR RAMPANT NEPOTISM.

DEAR SIR,—Is it so rare in the Metropolis to find one, whether among Southwark aldermen or not, who at every pause find it necessary to cast disparagement on the man of brains who works and is an engineer?

Why, we in the country towns find plenty of the same kidney, not only among aldermen and councillors (who, by the way, generally have a poor relation to provide for when they talk so), but among municipal managers who have themselves been "pitchforked" into their position through political influence, and have to a great extent to rely upon engineers to pull them safely through; yet these same men have the audacity to tell their subordinates—engineers who have been all through the works—to their face that "an engineer is a mere cipher, that they are nowhere." In the same breath the pitchforked man orders the subordinate to prepare a report or series of notes (commonly called "particulars") on such-and-such a thing, for the said "I am" to use as his own material and ideas in a paper or lecture before some association. One very prominent individual of this tribe, who calls himself an engineer and manager should—if he had his due—be working out a term (learning engineering) in a quarry of one of H.M. penal settlements.

No, sirree, what you find in London is not new in the country, not by any means. But are not the engineers themselves to blame? What is the use of an association if it is not run also on the lines of combination and fellowship? And where does that come in when persons who are *not* engineers at all can get into the said circle?—THE GHOST.

THE METRIC SYSTEM IN MECHANICAL AND ELECTRICAL ENGINEERING.*

Introductory Statement for the Metric System.

BY ERNEST R. BRIGGS.

1. It has been wisely decided that the discussion on the metric system by this society should be as strictly confined

* Paper read before the Rugby Engineering Society, Oct. 6.

Digitized by Google

to the mechanical and electrical branches of engineering as the ruling of the chairman can make it; nor need this be considered a restriction that is in any way irksome, since in the application of the metric system to the mechanical workshops of to-day there are more controversial points than could possibly be exhausted in a much longer time than that which the council have arranged for this debate.

2. An opening statement may either skim lightly over numerous points, being a general survey of the whole question, or attention may be drawn in greater detail to portions of the subject, leaving many phases of the subject untouched. No doubt it is rather in the province of the opener of a debate to direct attention to the various strategical points of the debate; nevertheless, the present writer is of opinion that it would be better to refer more fully to one or two details which become prominent in the actual application of the metric system to mechanical workshops, leaving other speakers to bring forward further points, as, doubtless, they will be anxious to do.

3. The most elementary question which naturally presents itself is, "Why should we adopt the metric system?" Leaving aside the wider interpretation, the answer is, "Because of the ever-increasing necessity for an international system of weights and measures." Admitting such necessity, the questioner next asks, "Why should we change our system of weights and measures, instead of the Continental nations changing theirs?" to which we reply, "Because the metric system of weights and measures is greatly superior to the Imperial system." With the advocates of the metric system rests the *onus probandi*.

4. The superiority of the metric system shows itself more in its application to the industries under discussion than in almost any other connection, and it is the engineer, above all, who recognises the imperative importance of an international system. Moreover, the fact must not be lost sight of that the engineer in the past had to use such units as were at hand, and it is, therefore, hardly to be expected that the inch and foot would be the best units that could be adopted for his purpose.

5. As it is pertinent to the engineer that an international system of weights and measures should be adopted, it may be advisable to add a word or two as to the reason why this is so. An example will serve to illustrate the point. Some 60 or 70 years ago every mechanical engineer of note had his own standard of screw threads, under the mistaken impression that he was protecting his business. The result was, however, a failure, and out of the chaos order was brought about through the Whitworth threads predominating by the masterful genius of the great mechanic. So in all branches of engineering can be traced the growth of local trade into national trade, in only too many cases against the blind opposition of many men of the day. History repeats itself. Here, at the opening of the twentieth century, the same state of affairs is present. National trade is making rapid strides into international trade. Trade standards, tariffs, wars, cannot stop it. Better to take a leaf out of the past and help it. In the case of the screw threads referred to above, there exists at the present day the principal standards of screw threads in use for ordinary fastenings—viz., the Whitworth, the Sellers, and the S.I.—examples of which may be found in any country or any town of a manufacturing people. The number of Sellers and S I. threads in use in this country is rapidly increasing, due to the growing importation of American machine tools and German and Swiss electrical machinery. The same state exists in Germany, and even in America. This fact, typical of the whole question, may be left to speak for itself.

6. In the meantime it is necessary to examine somewhat the respective values of the inch and millimetre as units of measurement for the mechanical and electrical engineer. A unit of length within the limits of this debate may be defined as the medium by which the size of a piece of machinery is conveyed from the mind of the designer to the hand of the constructor. It, therefore, follows that the most suitable unit for the purpose is that which will enable a dimension to be written with as few symbols as possible, but at the same time will also allow a fine limit in which to express the size required. For example, a large unit would call for few symbols provided the distance to be measured was exactly equal to some multiple of the unit employed. But the larger the unit the smaller the chances of the distance being an exact multiple. On the other hand, the smaller the unit the more symbols required, and the greater the chances of the distance being an exact multiple. It is obvious that there is an average convenient unit of length. What is it?

7. The most casual examination of working drawings brings out the fact that although the inch is nominally the smallest Imperial unit of length, yet the designer has been compelled to construct a new one by continual subdividing until he has obtained a $\frac{1}{16}$in., which is really his unit of length. As there is no recognised name for this virtual unit, it is written as a vulgar fraction in terms of the inch. Hence, in order to express a dimension up to 1in. it may be necessary to employ as many as four figures (not to speak of dashes and ticks); up to a foot, six figures.

8. On the other hand, the metric system supplies a unit of length, the millimetre, exactly suited to the requirements of the engineer. By its means any dimension up to about 4in. can be expressed in two figures, while up to about 40in. requires only three figures. The millimetre being a smaller unit than the $\frac{1}{16}$in., also permits of finer limits being used. Such a system thus permits of fewer figures being used on drawings, allow a finer expression of the required size, and by means of a simpler notation greatly reduces the chances of error on the part of the workmen reading the drawings.

9. By far the most controversial point in the application of the metric system is that of screw threads. As to the absolute value of the three systems, there can be no doubt in the superiority of the S.I. threads. The table in the appendix gives the sizes of Whitworth threads most usually employed, with the diameter increment; also a selection of S.I. threads which would meet ordinary requirements.

10. A large amount of misconception arises when dealing with the screw thread question by the supposition that a change from the Imperial to the metric units must be accomplished in a short space of time. This need not be the case at all, even supposing that the present Imperial system of weights and measures be made illegal, so long, of course, as the illegal weights and measures were not made a medium in the sale of the manufactured article. With a new firm starting business it is just as convenient to adopt the metric system in full—that is, to go the "whole hog" with S.I. threads—as it is to adopt the Imperial system. On the other haad, with a firm who have been in business for some years, and who have sunk a large amount of capital in small tools and gauges, the matter is different. In such a case it is better to wait until an opening occurs, such as the introduction of a new speciality, or the complete revision of the existing one, before attempting the introduction of the metric system. If the conditions are not favourable for the adopting of the S I. threads, the Whitworth may still be used without great inconvenience, until a better opportunity presents itself.

11. The above remarks are intended to refer only to the use of screw threads for ordinary fastenings, such as bolts, studs, etc.; in work of a special nature requiring screw threads—for instance, the square threads used so much in machine tools, etc.—metric pitches should at once be adopted. This does not present any difficulties with regard to lead screws for lathes, since by means of a 127-tooth wheel, metric pitches can be cut with an error which is considerably less than the ordinary manufacturing limit. The reason for this being that 127mm. is equivalent to 5·000004·351 inches, thus giving an error of less than five-ten-thousands (0·0005) of an inch in a length of 40ft.

12. Another important point in which there should be no delay when once a start has been made is in the adopting of metric pitches for gear wheels. Metric cutters of standard sizes can be obtained from any dealer, either from stock or to order. For bevel gears there is even less

Digitized by Google

trouble, as they can be cut on the usual machines as well as gears called for in Imperial measures.

13. Although the adoption of metric weights and measures of capacity is relatively a small matter by comparison with that of linear measurement, yet, looked upon from an absolute basis, they are of great importance. The amount of time saved by getting rid of the necessity of converting the long string of tons, hundredweights, quarters, pounds, into pounds and *vice versâ* cannot be overestimated. There is no juggling with figures; the engineer uses only two units, the kilogramme (kg) and millier, or metric ton. He is not worried when stresses are expressed in both pounds per square inch and tons per square inch. When he is told that the head of a column of water is 100m., he has only to move a decimal point to know that the pressure on the base is 10 kg. per square centimetre. Should he be informed that the contents of a tank of water is 10 cubic metres, he knows at once that the weight is 10 metric tons, or 10,000 kg., and that its capacity is 10,000 litres. If a liquid is flowing through a pipe at a velocity of 10m. per second, and the section of the pipe is 400 square centimetres, it does not take him long to find out that the discharge is 100 decimetres × 4 square decimetres = 400 litres per second. Let him try with a speed of 100ft. per second, sectional area of pipe 400 square inches, to find the discharge in gallons, and he will say that the slide rule is the salvation of the Imperial system. The engineer using the metric system never has to reduce feet into inches, or fractions of an inch into decimals of a foot. In fact, he uses the same units for calculation as he does for measuring, which is distinctly more than the average British or American engineer does.

14. It must not be thought that the introduction of the metric system, with all its advantages of simplicity and freedom from error, can be introduced into a workshop merely by telling the draughtsman to figure his drawings in millimetres, and by giving the workman a metric scale. Far from it; the frailty of human nature has been the subject of many homilies, and it may be taken for granted that at the end of 10 years, nay, 100 years, would still see the existence of the Imperial system.

15 To introduce the metric system into a manufacturing concern, and to really gain by it, it is necessary first to get the chief draughtsman and the works manager enthusiastic on the question, and then to banish all feet, inches, pounds, and gallons from calculations, drawings, limits. The speeds and feeds of the machines must be expressed in metres per second or per minute, and in millimetres; all weighing apparatus must scale in kilogrammes, and kilogrammes only. The introduction must be thorough; of that there must be no question. There are men who, by application to the values of the units, have been able, in the short space of 12 months, or even less, to think not only in millimetres and kilogrammes, but also in compound units, such as kg./sq. cm., m./sec, etc.; while men who, although in daily contact with the system, have hardly taken the trouble to think even in millimetres in as much as five years. That is the key to successful adoption: get the men keen on it, and the transition period will be short and hardly felt.

APPENDIX.

Reply to the Introductory Statement.

BY R. C. JACKSON.

16. In moving an amendment to the resolution, it is to be noted that a restriction has been placed on the subject matter of this debate. It is not proposed to make any objection to this ruling, except to state that, in the writer's opinion, a correct judgment of the respective merits of the metric and Imperial systems of weights and measures as applied to mechanical and electrical branches of engineering, cannot be arrived at without taking a much wider survey of the principles and matters involved than can be debated within the limits laid down by the mover of the resolution and the time allowed for the purpose by the council.

17. In paragraph 2 a preference is stated for supporting the affirmative argument by some detail illustrations of the application of the metric system to mechanical workshops, etc. A reply to this is that until one is able to show that the fundamental units of the metric system are better in themselves, it is premature to discuss the detail applications of the units in question.

18. In paragraph 3 of the opening statement the metric system is stated to be greatly superior to the Imperial system.

19. The argument in support of the greater scientific accuracy of the Imperial system may be put shortly as follows: The Imperial system of weights and measures is found to be based upon a *straight* line of finite length—*i.e.*, the *axis* of the earth—as compared with the metric system, which is based upon a *curved* line—*i.e.*, a fraction of the *quadrant* of the earth's surface.

20. The answer to paragraph 6 is the one-thousandth part of an inch or the mil, a unit of length which appears to satisfy all the conditions claimed for the millimetre, but in a still better degree. For fine work fewer fractional readings are required. Examples will occur to anyone in connection with wire gauging and sheet metal work.

21. On the respective merits of the various screw threads now in use referred to, the writer puts forward no definite opinion, and prefers to let other speakers deal with this aspect of the case who have a closer practical knowledge of it. The very fact of the extensive use and successful competition of the Whitworth and Sellers standard threads alongside of the S.I. standard, shows there is little or no trouble experienced in the matter.

22. Since the metric system is, and has been, permissive for some time, it will, no doubt, become finally adopted by the country at large when it has shown its great superiority to the existing system of things.

23. MEASURES OF WEIGHT AND CAPACITY.—The late Sir John Herschel, in an address delivered before the Leeds Astronomical Society on Oct. 27, 1863, shows how a decimal relation may be established between the Imperial system of linear measurements and those of capacity and weight, similar to that existing in the metric system. He points out the fact of the length of the polar axis having been determined from the combined results of all the scientific measurements of arcs of the meridian to be equal to 500,482,296in. of our Imperial yard, and that if one five-hundred-millionth part of the polar axis were adopted as a new standard unit, to be called the "geometrical inch," it would differ from the Imperial inch less than one-thousandth part of an inch—a difference so small as not to be measured by any ordinary method, and only by the aid of the nicest scientific instruments. For all ordinary practical purposes the geometrical inch would be identical with the Imperial inch. The present legal weight of a cubic foot of distilled water at 62deg. F. is 997·145oz., being short by 2·855oz. of 1,000oz. If the linear foot were increased by the one one-thousandth part, the present deficiency of 3oz. approximately would be made up. Since the Imperial half-pint is the measure of 10oz. of distilled water, or the hundredth part of the capacity of the cubic foot, the ratios of these units of length, weight, and capacity would be thus brought within such practical limits of precision as would meet every possible commercial requirement The address concludes: "Thus the change would place our

Digitized by Google

system of linear measure on a perfectly faultless basis, it would at the same time rescue our measures and weights from their present utter confusion, and secure that other advantage of connecting them decimally with that system on a regular, intelligible, and easily remembered principle, and that by an alteration practically imperceptible in both cases, and interfering with no one of our usages or denominations."

24. It is urged that the address quoted from should be carefully read by all those who are interested in the study of the important subject of metrology.

25. An important matter which has not been referred to in the opening of this debate is this: Assume for granted the metric system to be all its advocates claim for it, how and by whom is the cost of alteration to be paid? Sir Samuel Montague, president of the Decimal Association, in advocating the use of the decimal system, has always assumed the Government would pay. Mr. M'Farlane, of the Westinghouse Company's Pittsburg factory, is reported to put the cost of changing in these works to the metric system at the large sum of 650,000dol. Colonel Tannet-Walker, of Messrs. Tannet-Walker and Co., Leeds, has put the cost of changing in their works at £7 to £10 per man employed. On a low estimate, Mr. Towne, of the Yale and Towne Company, states that one million dollars would not cover the cost to the engineering trades alone in the States.

26. Mr. Coleman Sellers, speaking in 1879, estimates the cost of the change in the machine shops of his company at £40 per man employed.

27. The following figures were all given by the respective firms and companies to a committee of the National Association of American Manufacturers, who, on Dec. 23, 1903, sent out a circular letter of enquiry. The replies were published in *American Industries* for April 15, 1904: The Long Arm System Company, Cleveland, O.; ship fittings; cost of 200,000dol. The introduction of the metre would be confiscation without compensation. Carnegie Steel Company, Pittsburg; armour plates; use of two standards in the same factory would entail endless confusion. The Miller Dubrul and Peters Manufacturing Company, Cincinnati; cigarette machinery; cost, 60,000dol. to 75,000dol. The Niles Tool Works Company, Hamilton, O.; machine tools; cost, 50,000dol. to 75,000dol. The Cincinnati Milling Machine Company; machine tools; cost not less than 100,000dol. E. C. Atkins and Co., Indianopolis; saws; cost, 50,000dol. to 75,000dol. North Bros. Manufacturing Company, Philadelphia; hardware specialities; cost, 50,000dol. Lane and Bodley Company, Cincinnati; foundry and machine works; cost, 200,000dol. to 500,000dol. Lidgerwood Manufacturing Company, New York City; hoisting engines; cost, 500,000dol.

28. The cost of conversion in the engineering workshops alone of the United Kingdom has been put at 100 million pounds.

29. Now, whatever the figure may be, the cost to those countries concerned would be enormous, and an additional drag on industries which are already sufficiently handicapped.

Resolution to be moved by Mr. E. R. Briggs: "That, in the opinion of this society, the advantages to be derived from the application of the metric system of weights and measures to mechanical and electrical engineering are so great as to outweigh the temporary inconvenience caused by the transition period; and that the hon. corresponding secretary be instructed to forward a copy of this resolution to the local engineering societies of this country, asking them to grant facilities for the discussion of the metric system by their members, in order to bring about its universal adoption as the international system of weights and measures."

Amendment to the above resolution, to be moved by Mr. K. C. Jackson: "That in the opinion of this society the alleged advantages of the metric system are insufficient to justify their adoption by this country, and that what is required is to simplify and standardise our present Imperial system."

GRAPHICAL DETERMINATION OF THE WEAR OF TROLLEY WIRES.

The *Elektrotechnische Zeitschrift* describes an instrument recently put on the market by Messrs. Dreyer, Rosenkranz, and Droop, of Hanover, for the purpose of obtaining a record in a simple and quick way of the amount of wear on overhead trolley wires.

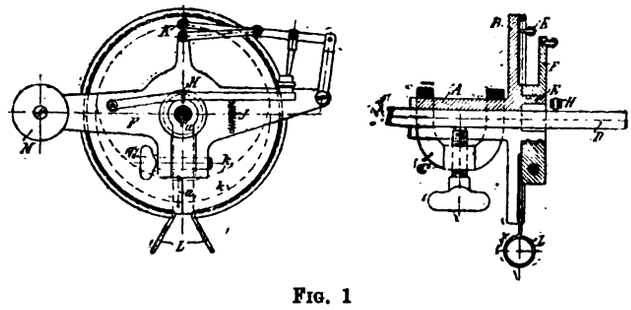

FIG. 1

It consists of a boss, A (Fig. 1), fitted with a wide flange, B, and arranged for clamping to the trolley wire, D, by means of the clutch, C. Both boss and flange are split so that they can be passed over the trolley wire in position. A species of crank, F, is attached to a projection, E, on the boss, and is arranged to be rotated about the latter. This crank also is split, and is held together by the screw, G. The motion of a scriber, H, pressed against the trolley wire by the spring, J, and moving round the wire as F is turned, is transmitted by means of levers giving a 10 : 1 magnification to the pencil, K. An annular sheet of paper is held against the flange, B, by means of the spring, L.

When the crank, F, is turned round by means of the knob, M, the pencil records the shape of the cross-section of the wire on the paper. Whilst the trolley wire is new and circular a circle k having an area 100 times that of the wire will be recorded. If, on the other hand, the wire were worn at one point to the extent a, the curve k' would be obtained, showing the wear a' enlarged 10 times. Fig. 2 shows a full-sized curve (dotted) obtained with this instrument on a trolley wire that had been considerably worn at one side by the collecting bow.

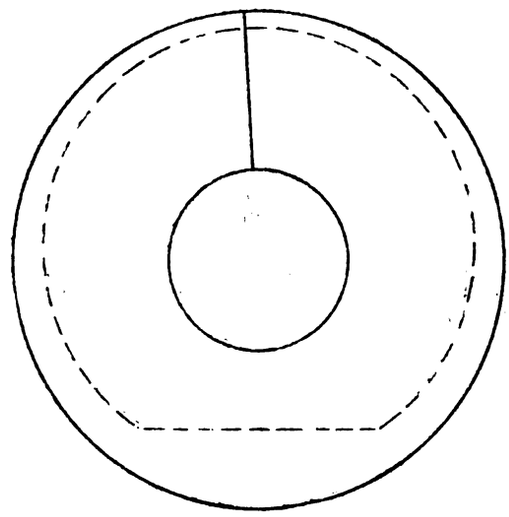

FIG. 2.

The apparatus should prove of considerable use on large tramway schemes, as, besides allowing the ordinary wear on straight lines to be recorded, it offers a simple method of deciding the satisfactory nature or otherwise of the trolley suspension arrangements at curves and crossings. By taking profiles of the wire at such points at regular intervals the gradual increase in wear could be followed, and any noticeable increase in wear could be counteracted by altering the suspension or tension arrangements. In this way it should be possible to reduce the number of wire breakages, with their accompanying inconvenience and expense, considerably.

FORTHCOMING EVENTS.

FRIDAY, OCT. 14.

Electro-Harmonic Society.—At 8 p.m., smoking concert.

SATURDAY, OCT. 15.

Glasgow Technical College.—At 7.30 p.m., presidential address to Scientific Society by Mr. R. W. Munro.

TUESDAY, OCT. 18.

London Chamber of Commerce.—At noon, meeting of the Postal, Telegraph, and Telephone Committee.

THURSDAY, OCT. 20.

Society of Arts.—At 8 p.m., "Automatic Regenerative Control of Electric Traction," by Mr. J. L. Hall.

FRIDAY, OCT. 21.

Institution of Mechanical Engineers.—At 8 p.m., "A Scientific Investigation into the Possibilities of Gas Turbines," by Mr. R. M. Neilson.

ECONOMICAL TELEPHONE CONSTRUCTION AT SWANSEA.

MR. A. R. BENNETT SHOWS THAT TELEPHONE LINES COST LESS THAN £16 EACH.

On Oct. 5 Mr. Tulloch, on behalf of the Local Government Board, held an enquiry at the Swansea Guildhall on an application of the Corporation to borrow a further £2,000 for the extension of their telephone system. The application was opposed by Mr. W. D. Benson, barrister, of London. He said he appeared on behalf of the Prince of Wales Dry Dock Company, the Ocean Dry Dock Company, and three other ratepayers.

Mr. A. R. Bennett, consulting telephone engineer, gave evidence on behalf of the Corporation, and explained that the original scheme was for 750 completed lines, together with ducts and poles for another 750, but without any spare cables or wires. This was estimated to cost £18,000. Subsequently, and as a matter quite apart from the telephone construction proper, the Corporation decided to erect a special building for the telephone offices and switch-room, for which the Local Government Board granted an additional £2,300. It had been found possible to greatly improve on the estimates; so much so that, instead of connecting 750 lines and instruments for £18,000, 1,003 lines and instruments had been completed for the sum of £15,769. 3s. 7d., or only £15. 14s. 6d. each. In addition, a large number of spare cable lines had been provided in excess of the estimates. It was true that several of the junction lines to branch exchanges within the area had not been completed, but there was sufficient money in hand to finish these out of the original grant, and, in point of fact, several were well on the road to completion. The £2,000 now asked for was required to lay new ducts in certain directions and draw in new cables, so as to render the spare wires, which had already been laid, available for connecting the new subscribers who daily applied for Corporation telephones. There were 176 unexecuted orders on hand, and it was found difficult to reduce the number, as new applications were received as soon as old ones were wiped out. A portion of the £2,000 would be devoted to completing the multiple switchboard at the central exchange to take 960 subscribers' lines.

Mr. Benson did not call any evidence against the Corporation, but spoke for about an hour, arguing that the borough rates were already so high as to render it inadvisable to increase the ratepayers' liability, and also calling into question the accuracy of the accounts prepared by the borough accountant, which showed that the undertaking was being worked at a profit. The town clerk replied in a few words, and there is every expectation that permission to borrow the money will be granted at an early date. During the enquiry eulogistic remarks were made as to the very great efficiency of the Corporation telephone service as compared with anything that had ever previously been known in Swansea.

We take the following report from the *South Wales Daily Post* of Oct. 5.

The TOWN CLERK explained, with regard to the telephone matters in respect of which Mr. Benson opposed, that in November, 1902, the Local Government Board sanctioned the borrowing by the Corporation of £20,300 for the establishment of a municipal telephone exchange, and in April, 1904, a further sum of £306 was sanctioned, making a total for telephone matters of £20,606. Of that amount the Corporation had expended £19,158 19s. 4d., leaving a balance at the present time of £1,447. 0s. 8d. in respect of works not yet carried out. At the present time there were 1,003 subscribers' instruments and lines on the municipal system, and the rental from them amounted to £3,823. 10s. 5d. There were, however, 176 further applications for connections, and it was as regarded those applications that it was now desired to raise the sum of £2,000 to enable the Corporation to join up those subscribers. The balance in hand—£1,447. 0s. 8d.—could not be devoted to the purpose, as the original sanction was in respect of specific works other than that now contemplated. The details of the £2,000 were £460 for filling present multiple switchboard at central exchange to its maximum capacity, £30 for increasing capacity of switchboards at branch exchanges, £30 for extending test frames and adding test jackets and guards, £447. 11s. for new ducts and cable, £100. 1s. 4d. on another section, £150 for small cable for branches, £231. 5s. for additional subscribers' instruments, and £521. 2s. 8d. for joining up subscribers.

The CONSULTING ENGINEER gave evidence, and said he was consulting adviser on telephones to several other corporations—Glasgow, Portsmouth, Brighton, Hull, etc. He explained that the scheme sanctioned in 1902 was to provide for 725 subscribers, including the necessary junction lines, and 25 public telephones—in all 750 completed lines. Of these 700 were to be connected in Swansea, and 50 in other places within the telephone area. The scheme also provided for the provision of spare ducts and spare accommodation on distributing poles to the extent of another 750 lines, but did not include any spare cables or other spare wiring. Subsequently it was decided to erect a special exchange and office premises at a cost of £2,300, which amount was included in the loan sanctioned, and later on permission was asked to spend a further sum of £306 on the provision of a junction cable to the National Telephone Company's exchange for the purposes of intercommunication, which was granted. The lines of ducts within the borough had been substantially carried out with slight deviations in the duct routes, as were shown to be expedient by the grouping of new subscribers. The total length of the excavations carried out was 6 miles 775 yards, a slight excess being caused by the number of distributing points being increased from 57 to 60, and to the use of underground cables at two places on the Morriston route, and one place on the Mumbles route. Spare ducts of a total length of a mile and 303 yards had been laid in excess of the original estimate, and a considerable number of spare cable wires which would come in useful hereafter, and reduce the cost of future work. Until the success of the system had been demonstrated locally, the Telephones Committee were unwilling to proceed with the proposed junction lines from Swansea to the Mumbles, Swansea to Morriston, Swansea to Skewen, Swansea to Gowerton, Loughor, Gorseinon, and Pontardulais, Morriston to Skewen, and Morriston to Clydach and Pontardawe, representing 31¾ miles of pole route. Consequently those junction lines had not all been finished. Those completed were to Mumbles, Morriston, and Manselton, while others partially completed were Swansea to Skewen, Morriston to Skewen, Swansea to Loughor, and Morriston to Clydach. The total length of junction poles erected was 13¼ miles, leaving 18½ miles still to do, the estimated cost of which was £1,009. Against that they had £2,230. 16s. 5d. of the grants still unexpended. Owing to a number of the subscribers in Swansea being within a short distance of the exchange, it had been found possible to connect many more instruments than it was at first thought prudent to reckon upon without exceeding the loan sanctioned, but instead of the 750 completed lines contemplated, there were 1,005 now working. Deducting the capital still unexpended, and the value of the material in hand, it would appear that those 1,005 lines had cost £15,769. 3s. 7d., or only £15. 14s. 6d. each. Including the cost of the building of the exchange premises, which was not in the original estimate, the cost per line would be £18. 0s. 2d. For the purpose of joining up the new subscribers who daily made applications for telephones, it was imperatively necessary to provide additional ducts, cables, instruments, and switchboard accommodation, and the proposed new works would provide for at least 100 additional subscribers.

Mr. Bennett was cross-examined by Mr. BENSON at length. Counsel sought to show that only the telephone works within the borough, with the exception of the Mumbles exchange, had been completed; but the consulting engineer explained that on almost all the outside sections overhead work, such as the erection of poles, was well in hand, while the necessary underground work within the borough in connection therewith was completed. By far the most expensive part of the work, in other words, was completed on those partially-finished portions. The wiring was a comparatively small matter. It was more economical to erect the poles first and then do the wiring as one job.

Digitized by Google

By the Inspector: He certainly expected to complete all the works in the original estimate for the £2,230 still unexpended, because they had been working very much cheaper than the estimates all through.

Mr. Benson: You have already spent £19,000 in doing what portion has been done in the borough without one extension outside?

Mr. Bennett: No, there is Morriston.

Mr. Benson: Morriston is in the borough.

Mr. Bennett: But it costs money.

Mr. Benson: Of course it does. But I say you have already spent £19,000 in the borough and Morriston and practically not gone outside? The amount is £19,158.

Mr. Bennett repeated that all the real expense was in putting up poles, and the expenditure on wiring was comparatively cheap.

The Inspector: Your question is whether these outside lines can be completed for the balance of £1,447?

Mr. Benson: That is what it comes to.

The Inspector: And Mr. Bennett says emphatically yes.

Mr. Bennett: Without any doubt.

Further cross-examined, Mr. Bennett said that the cost of wiring a metallic circuit was about £12 per mile, using the Post Office specification of 100lb. of wire to the mile. Taking the erection of the poles, the cost would be £50 per mile. He would not admit that when it was decided to proceed with 750 lines, or half the number originally estimated, that this number should have included the junction lines, but did admit that when the junction lines were completed, individual subscribers would have to be joined up and extra money would be required for that. At the same time the revenue would be increasing. Regarding spare accommodation, the consulting engineer pointed out that at several points there were spares that could only be utilised by the expenditure now desired in order to lay in new cables and splice them up with the spare accommodation. In other places the size of the cable ducts had been increased to admit of additional cables. He would not agree that what was known as outside extensions simply meant extra wiring, as very often a new cable had to be taken in and out of the building. The reason that a cheaper tariff was made was because there was less work in the operating-room than with direct lines. Nothing had been allowed for depreciation, as it was a burning question with auditors as to whether it was necessary to provide for that, seeing that the life of the undertaking was as long as the loan by which time the money would have been repaid. In the case of the Swansea system, however, everything was kept at such a high state of efficiency—new material being used for all repairs—that no depreciation account was necessary. The sum of £200 per annum was set apart for repairs, and he estimated this to be quite sufficient, together with an amount for depreciation, although the capital outlay was over £20,000.

Re-examined: No portion of the £2,000 would be expended in providing the junction lines. Those would be completed by the £1,447, plus £783, the value of material in stock.

Mr. Benson put it to Mr. Bennett that subscribers had only consented to come on to the system on intercommunication being promised.

The Town Clerk said that was a question between the Corporation and the National Telephone Company that would have to be decided in the law courts.

The Borough Accountant gave evidence. In reply to Mr. Benson, he said the rates amounted to 8s. 4d. in the £.

Mr. Benson: That is pretty high—an increase of 6d. since 1903.

Mr. Benson then addressed the inspector, stating that he represented clients whose assessable rateable value was £4,400, and they objected to the application because experience in other towns, and now with Swansea, was that there was no limit to municipal trading concerning telephones. He did not believe for one moment that if the accounts of Glasgow, Portsmouth, and other places where paper balances were shown in connection with their telephone systems, were properly audited and depreciation allowed, any profit would be shown at all. Glasgow three years ago began with a capital liability of £100,000. Since then it had increased to £331,000—a tremendous liability to the ratepayers. In Swansea the Corporation were pledged up to £20,600, and notwithstanding that the scheme was not carried to the outlying parts, they were now asking for money. There was no limit to it. He contended that the junction lines should have been provided at the outset, and suggested that the Corporation had not acted *bona fide* in the matter.

The Inspector said he was not clear that under the Local Government Board sanction the Corporation were bound to carry out those works. At any rate, the money had not all been spent. Had the outlying districts been connected, would Mr. Benson's clients have then been satisfied?

Mr. Benson said intercommunication would then have been brought about probably and the *bonâ fides* of the Corporation shown. Learned counsel proceeded to comment on the loss sustained by the Corporation waterworks, and adversely criticised the working of the electric lighting station, which in 1903 showed a profit of £1,810 without any provision being made for sinking fund or depreciation.

The Town Clerk said the 1904 report showed a substantial profit after providing for sinking fund and depreciation to date.

Mr. Benson said it was childish to say that £200 would cover repairs and allow for depreciation on an undertaking costing over £20,000. His clients were already very heavily rated, and very soon the liability of the telephone system would be £40,000, or even more. As soon as new subscribers came on fresh capital would be necessary, and, therefore, in the interest of the ratepayers, the present application ought not to be sanctioned.

The Town Clerk hinted that the National Company were behind the opposition, and urged that the telephone scheme must now go on. There was no intention on the part of the Corporation to abandon any part of the original scheme, and if the undertaking proved to be the success that was hoped for it, more moneys, of course, would be necessary, and the Corporation would look forward to making more calls.

Mr. Benson: For how much, Mr. Thomas?

The Town Clerk: That depends entirely upon the success of the scheme. Mr. Thomas added that there was nothing before the Corporation that led them to believe the concern was going to be a failure.

This concluded this part of the enquiry, and the inspector then heard evidence concerning the need of the sanitary accommodation above referred to.

TRADE NOTICES AND NOVELTIES.

The "Wirt" Dynamo Brush.

Messrs. J. Defries and Sons, Limited, of 146 and 147, Houndsditch, E.C., are putting on the English market the "Wirt" dynamo brush, which is worthy of the attention of electrical engineers as a whole. This brush, which we illustrate in Figs. 1 and 2, is of the metallic type, and is designed to enable dynamos to run without sparking at the commutators. The means by which this is effected will be clear from the illustrations, which show that the brush is a composite one. The inner

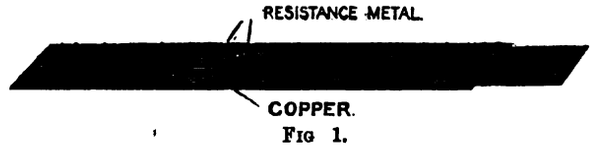

Fig 1.

laminations are of copper, and the outer laminations of high-resistance material. As regards sparking, the result is that while there is not a high resistance in the path of the current, there is a considerable resistance between the heel and toe of the brush. It is this function in the carbon brush which greatly assists in securing sparkless collection, and the construction of the "Wirt" brush produces this good quality without necessitating the larger commutator needed for the carbon brushes.

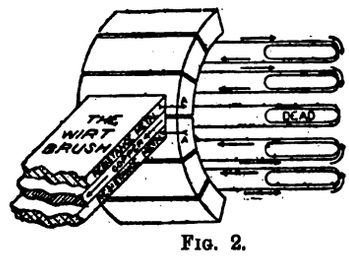

Fig. 2.

We understand that the large manufacturing firms in the United States have adopted the "Wirt" brush extensively, and it will enable engineers in this country to readily reduce the sparking on machines designed rather too close to the sparking limit. The brushes are made in a great variety of thicknesses and breadths, so that there should be little difficulty in changing over from a copper brush to one of the "Wirt" type.

Berliner's Telephones.

The telephone instruments illustrated herewith are of a special type introduced by the Berliner Telephone Manufacturing Company, 200, Upper Thames-street, London, E.C., to meet the requirements of what is now known as the "Reply and call" system, which, in certain circumstances, has advantages over ordinary intercommunication systems. With the latter, any department can speak to the other at will direct, without requiring a central station. It is, however, sometimes advisable that only the principal should be able to communicate to the various departments, and, *vice versâ*, the departments not to speak to one another except through the principal. In these circumstances the "Reply and call" system will be found

Digitized by Google

useful. The central-station instrument (Fig. 1) is fitted with the firm's patent automatic replacement levers, and the principal, if he desires to speak to any department, has only to take the hand combination off the hooks, pull down the lever of the number required, ring, and then speak; replacing the hand combination automatically restores the lever. This telephone is also provided with a pair of through-connection plugs, enabling the principal to place any two departments in direct communication with each other, and he can, if he wishes, call up and speak to several departments at the same time by simultaneously pulling down the levers of the numbers required.

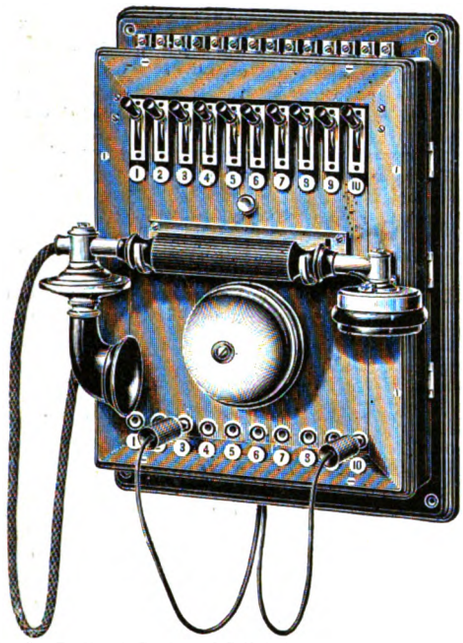

FIG. 1.—Berliner's Reply and Call Automatic Wall Telephone for Central Point.

The automatic side station (Fig. 2), designed for use with the "Reply and call" system, dispenses with the two-way switch hitherto necessary, thus doing away with the trouble and confusion caused by leaving the switch in the wrong position. The act of calling the central station automatically changes over the call line, whether the receiver is on or off the hook. Directly the receiver is replaced the connection is automatically restored to the reply line, leaving the instrument ready to receive a call. Several patterns of these instruments are made, which, together with a large variety of the firm's "Twencen" domestic and

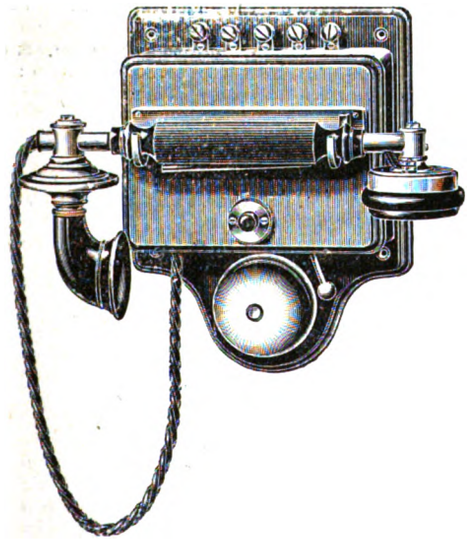

FIG. 2.—Berliner's Reply and Call Automatic Side Station Wall Telephone.

other telephones, are dealt with in a list just published from 200, Upper Thames-street.

Electric Radiators.

We illustrate herewith several electric radiators of new design manufactured by the General Electric Company, Limited. The "Dolphin" pattern (Fig. 1) is of very ornamental appearance, and suitable for dining and drawing rooms, state cabins, etc. It has a hammered iron base, and is fitted, as shown, with three lamps and two switches. Fig. 2 illustrates a radiator of the ornamental "Diaper" type, mounted in a handsome lacquered and polished cast-brass framework, and suitable for dining or drawing rooms. This is one of several patterns of the same type supplied, being wired on the enamel system, and, therefore, non-luminous. The "Car" radiator (Fig. 3) is very strongly constructed, and so arranged that the connections may be taken direct through the floor of tram or railway car. There are no loose coils to cause short-circuits. Other types

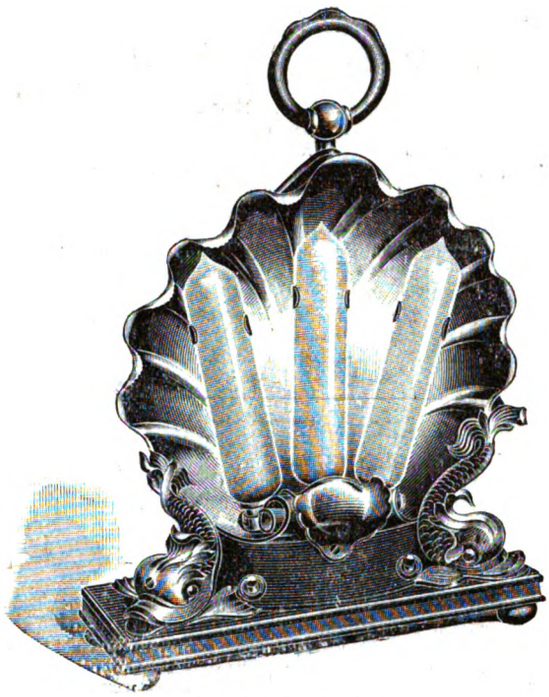

FIG. 1.—G.E.C. Dolphin Radiator.

and patterns of these radiators are illustrated and described in a neat little pamphlet just issued by the firm in question. It may be added that the "Luminous" or "Glow" pattern radiators are each fitted with a polished aluminium reflector, which only requires the most occasional rubbing with a dry cloth to keep it in perfect condition. The

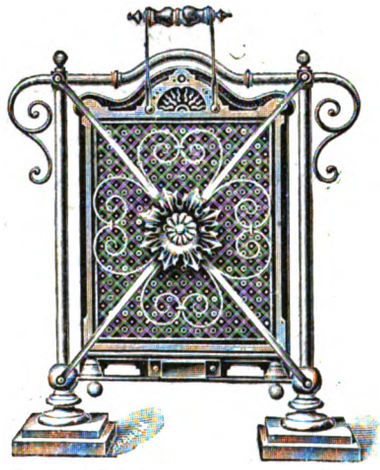

FIG. 2.—G.E.C. Ornamental Diaper Radiator.

heating lamps can be instantly fixed in the event of renewals. Special care, we are told, has been given to the design of these lamps, which have now been brought to a high stage of perfection. Their life is extremely long, and the heating effect well maintained throughout. All the radiators are provided

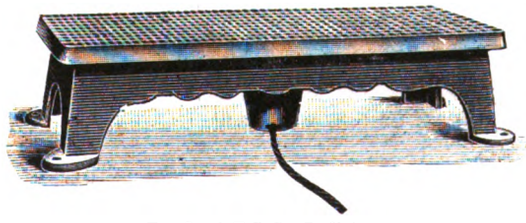

FIG. 3.—G.E.C. Car Radiator.

with an improved form of holder, which ensures a perfect connection. Included in the pamphlet mentioned are also some particulars of a useful form of heating pad designed to supersede hot-water bottles and poultices, from whose objectionable features it is free, besides being more effective and ready for use at a moment's notice.

LEGAL INTELLIGENCE.

DEFECTIVE TELEPHONES.

A case of importance to telephone subscribers was tried in the Mayor's Court, before Sir Forrest Fulton, K.C., and a jury.

The National Telephone Company sued Mr. A. C. M. Jenkins, of Leadenhall-street, to recover £18. 5s., a year's subscription for the use of a telephone. The defendant had refused to pay a year's subscription due in advance on the ground that between Sept. 28 and Dec. 9, 1903, the company had not kept the line in good working order. It was stated that between Sept. 28 and Nov. 30 the defendant could neither send nor receive a message, and he was constantly having trouble with the instrument. The plaintiffs admitted that they had received complaints during the time mentioned, but that the defects were immediately set right. One of the clauses to the agreement provided that in the event of the line not being in good working order the company should repair it with all possible haste, but were not to be held liable for any delay provided reasonable endeavour was made to restore communication as speedily as possible. That, it was urged on behalf of the company, had been done.

In the end the jury found that the line was not in working order, and judgment was entered for the defendant on the claim, and also on a counter-claim which he had raised for the agreement to be delivered up and cancelled.

TRAMCAR OBSTRUCTION.

At Leigh (Lancashire) Police Court, on Monday, Mr. George Shaw, managing director of the Leigh Brewery Company, and four of his carters, were again charged with wilfully obstructing a South Lancashire Tramway Company's tramcar, between Leigh and Lowton, on March 11 of last year. The case, which was chronicled in this journal at the time, had been remitted to the Leigh magistrates, who in the first instance had refused to convict, by the King's Bench Division, with a direction from the Lord Chief Justice that there was no absolute right on the part of a vehicle to keep the left-hand side of a road, but on a tramcar and a vehicle meeting they should act reasonably towards each other. The facts were that the car and the defendant's van encountered each other in a narrow part of the road, and as the driver of the van refused to cross over to the other side, where there was more room, the car was detained for over three-quarters of an hour, when it backed to a loop.

After a long hearing, the **Chairman** said the Bench were equally divided on the matter, and as he would not give a casting vote, no decision could be given. The tramways company could, if they liked, bring the case up again before another bench, or let it drop.

COMPANIES' MEETINGS AND REPORTS.

EDISON AND SWAN UNITED ELECTRIC LIGHT.

The report and accounts for the year ending June 30, 1904, show that the sum of £42,603. 17s. 9d. has been brought forward from profit and loss account. Interest on debenture stock has absorbed £18,760. 18s. 4d.; £11,000 has been set aside as depreciation on freehold and leasehold property, plant, machinery, and tools; £1,442. 13s. 11d. has been applied in writing down values of stocks; and the sum of £1,508. 8s. has been reserved on account of bad and doubtful debts. A further sum of £1,000 has been added to the reserve for future stock depreciation. After providing for the foregoing, the result as shown in the net revenue account is a credit balance of £8 891. 17s. 6d. At meetings of shareholders held on May 12 and 30, 1904, a resolution was passed reducing the capital of the Company by £2. 10s. per share on each of the 23,564 B shares of the Company. This resolution was duly confirmed by the court on July 26. Effect has been given to it in the account as now presented. As a result of this writing down of capital a debit balance of £3,589. 14s. 7d. remained, and deducting this from the balance of £8,891. 17s. 6d. as mentioned above, leaves a credit balance of £5,302. 2s. 11d. to be carried forward. Cost of establishing the business, goodwill, etc., £443,451. 8s. 1d., has been brought forward at the figures standing in the last balance-sheet. A sum of £1,029. 7s. has been expended on capital during the year. The shares of the Altrincham Electric Supply, Limited, have been taken at par, as in previous years. The indebtedness of this company has been reduced during the year by £1,466. 10s. 1d.

CUBA SUBMARINE TELEGRAPH.

The report for the half-year ended June 30 last, to be presented at the meeting on the 19th inst., states that the total receipts of the six months were £18,716, while expenses (including the cost of the attempted repair of the Cienfuegos-Santiago 1875 cable) amounted to £14,039, leaving a balance of £4,676, to which has to be added £6,971 brought forward, giving a total of £11,647 to be dealt with. The dividend on the preference shares will absorb £3,000, and leave £8,647, out of which the directors recommend a dividend at the rate of 5 per cent. per annum on the ordinary shares; the balance, £4,647, being carried forward. Payments to June 30 on account of the Cienfuegos-Santiago new cable have been charged to the reserve fund, which now stands at £144,932. The directors regret to report that the Cape Cruz-Santiago section of the Manzanillo-Santiago cable became interrupted on June 14. The cable is being repaired. This interruption accounts for the falling off in the receipts during June, as shown in the statement. The applications to the United States Government for payment of the claim for the cost of repairing the damage done to the cables during the Spanish-American war, and to the Cuban Government for payment of the subsidy for the coast cables, are still unsettled.

NORWICH ELECTRIC TRAMWAYS.

The report for the year ended June 30 last states that the earnings show an increase over those of the previous year, traffic receipts having amounted to £34,720, against £33,516 in 1903. The result of the year's working is a gross profit of £10,768, to which has to be added £201 interest received and £1,213 brought forward. Deducting from this £2,640, being 4 per cent. interest to June 30, 1904, on the outstanding mortgage debentures, and £1,012 which the directors have placed to reserve account, there remains a profit of £8,529. The directors recommend that a dividend of 3 per cent. be paid on the shares for the year, leaving £609 to be carried forward. The reserve will then stand at £3,197. The operating expenses for the year show an increase of £85. The number of passengers carried was 7,461,718, and the number of car miles run was 1,088,951.

SOUTH LANCASHIRE ELECTRIC TRACTION AND POWER.

An extraordinary general meeting of this Company was held at Liverpool on Friday, at which a resolution for the voluntary liquidation of the Company was passed. Mr. Arthur Stanley, M.P., explained at the ordinary meeting (which preceded the extraordinary meeting) that voluntary liquidation would facilitate the reconstruction of the Company, and ensure the interests of the creditors and shareholders being looked after.

NEW COMPANIES REGISTERED.

City of Buenos Ayres Tramways Company (1904), Limited (82,214).—Capital, £1,240,000. Objects: to acquire certain of the assets of the City of Buenos Ayres Tramways Company, Limited (now in voluntary liquidation); to acquire, or construct, maintain, work, and control any tramways, railways, roads, ways, canals, telegraphs, telephones, gas and electric lighting or power works, etc. Registered office: 1, Great Winchester-street, E.C.

Marks and Hodgkinson, Limited (82,265).—Capital, £5,000. Objects: to acquire the business of electricians and electrical engineers carried on by J. Marks and H. Clarkson, to adopt an agreement with J. Marks and W. B. Hodgkinson, and to carry on the business and that of manufacturers of and dealers in electric lighting plant, apparatus, and fittings, etc.

Rectophone Company, Limited (82,178).—Capital, £20,000. Objects: to adopt an agreement with H. G. A. I. Wieder and H. Knudsen, and to carry on the business of mechanical engineers, makers of and dealers in phonographs, sound producing and transmitting appliances, etc.

Liens Registered.

Electrolytic Alkali Company, Limited, Middlewich.—Lien registered Oct. 1, for £10,350 4½ per cent. first mortgage debentures, part of £50,000 authorised; trustee: Liverpool Mortgage Insurance Company, Limited; charged on the undertaking and all the property for the time being, including the uncalled capital.

Mexico Electric Tramways, Limited, London, E.C.—Trust deed registered Oct. 5, for £500,000 second debenture; trustees: L. Breitmeyer and C. Rube, 1, London-wall-buildings, E.C.; charged on certain ordinary shares and second mortgage debentures of the Compania de los Ferro Carriles del Destrito Federal de Mexico, subject to £400,000 first debentures, and on all other assets.

Motor Traction Co., Limited, London, S.E.—Lien registered Oct. 5, for £500 6 per cent. debentures; no trustees; charged on the stock-in-trade, loose machinery, and tools.

South Metropolitan Electric Light and Power Co., Limited, Blackheath.—Lien registered Oct. 3, for £53,292 4½ per cent. debentures, part of a series not to exceed the amount of the issued and paid up share capital; amount previously issued, £120,000; charged on the undertaking and all the property, present and future, including the uncalled capital.

PERSONAL.

Mr. Saunders, tramways manager of Lowestoft, has been granted an increase of £20 per annum.

We are informed that Mr. Fred. C. Gibbon, M.I.E.E., has again returned to Messrs. Browett, Lindley, and Co., Limited, under agreement for a long period, as sole managing director. Mr. Gibbons was formerly one of the company's joint managing directors, but severed his connection 12 months ago to take up the position of representative in England of Messrs. James Howden and Co. As our readers are aware, the company have devoted their attention to the production of vertical steam-engines for driving electric generators from the earliest days of this industry. We learn that for the future all these engines will be fitted with efficient shaft-throttle governors, simple and reliable, and equal in economy to automatic governors, which have been such a source of loss and trouble to the company in the past.

The borough electrical engineer of Poplar has tendered his resignation, which has not yet been accepted.

The Swindon Town Council have resolved that Mr. F. E. Jordan, switchboard attendant at the electricity works, be appointed shift engineer at the works at a salary of £84 per annum. It is also pro-

Digitized by Google

posed that the salary of the electrical engineer, Mr. J. G. Griffin, be raised from £250 to £300 per annum, and that of the assistant electrical engineer, Mr. R. W. Grubb, from £100 to £130 per annum.

Many will miss in Mr. John Hollingshead, whose death we regret to note took place on Monday, not only another link with the past, but one of the best-liked men of their acquaintances. Best known as founder of the Gaiety and the Alhambra, he was a man of no inconsiderable literary attainment. He was on the staff of *Household Words* under Charles Dickens, of the *Cornhill Magazine* under Thackeray, and on *Good Words* under Dr. Norman MacLeod. His monograph of Leicester-square is well known. What we are especially concerned in is that he introduced the electric light to England in 1876.

Mr. Blair, of Woolwich, has been appointed resident electrical engineer at Acton.

APPOINTMENTS VACANT.

Assistant Electrical Engineer, Erith Urban District Council. See advertisement.

Assistant to Canvasser, Woolwich, £2. 2s. per week, Oct. 22. See advertisement.

Canvassing Engineer, Wolverhampton, Oct. 31. See advertisement.

Pupil, corporation lighting and power station. See advertisement.

Improver, Mansfield. See advertisement.

Resident Agent or Manager for Singapore electric tramways.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Swansea.—Tenders are required for altering an engine, rewinding dynamo, etc.

Brighton.—Tenders are required for installing electric light in the diphtheria pavilion at the sanatorium.

Barrow-in-Furness.—The Corporation invite tenders for arc lamps and accessories. Tenders by 18th inst.

Melbourne.—The Federal Postmaster-General requires tenders for 6,000 yards of telegraph cable. Tenders by Nov. 15.

Crejour (Roumania).—The Municipality require tenders for construction and working of tramways for 50 years by Nov. 7.

Middleton.—The Corporation invite tenders for dust destructor, boilers, etc., at the electricity station. Tenders by 25th inst.

Porto Alegro (Brazil).—The term for receiving tenders for an electricity station, already announced, has been prolonged to Nov. 30.

Pretoria.—The Commanding Royal Engineer at Army Head quarters, Pretoria, is calling for tenders for the electric lighting of cantonments.

Ipswich.—The Corporation invite tenders for the supply of continuous-current meters for the ensuing 12 months. Tenders by 24th inst. See advertisement.

Mexico.—The Federal District Railway Company of Mexico require tenders for the electrification of six tramway lines in the town. Applications are to be made direct.

Wandsworth.—The Borough Council require tenders for electric lighting and ventilation of Council House. Tenders by Oct. 18. Full particulars in advertisement columns.

Richmond (Surrey).—The Guardians invite tenders for the installation of electric telephones at the workhouse, Grove-road. Tenders to the Guardians by 4 p.m. on 27th inst.

Pangbourne.—Tenders are required for lighting the village during the coming winter, for the Pangbourne Parish Council. Particulars may be obtained of Mr. C. West, jun., clerk.

Rugby.—The Urban District Council invite tenders for the supply of about 440 yards of ·15 three-core low-tension paper-insulated and lead-covered cable. Tenders by 25th inst. See advertisement.

Fulham.—The Council invite tenders for the supply and erection of a 3,000-volt main generator switchboard at their generating station, Townmead-road, Fulham. Tenders by 19th inst. See advertisement.

Great Western Railway.—The Directors of this Company are prepared to receive tenders for the supply of various stores from Dec. 1 next to Nov. 30, 1905. Tenders by Oct. 17. See advertisement in last issue.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Cumberland and Westmoreland Lunatic Asylum, Carlisle.—Tenders are required for plant. Copies of tender may be inspected at the office of the Consulting Engineer, Electricity Works, Northallerton, Yorks. Tenders to the Clerk to the Committee of Visitors by Nov. 1.

Mexico.—A consular report states that there is at present a demand for the undermentioned classes of manufactures: electrical accessories for street railways, including traction, rolling-stock, rails, posts, cables, etc., electric conduits, electric motors and other accessories for motive power, irrigating machinery, steam and electric.

Rochdale.—The Tramways Committee require tenders for the wiring of car depôt. Applications, with £1. 1s. deposit, to Mr. C. C. Atchison, borough and tramways electrical engineer, Rochdale. Extra copies 5s. each. Tenders, endorsed "Car Depôt Wiring," to be addressed to the Town Clerk, Town Hall, Rochdale.

Darlington.—The Darlington Co-operative and Industrial Society, Limited, invite tenders for installing the electric light in their offices in Priestgate, and their premises now in course of alteration in Corporation-road.

Sunderland.—The Corporation invite tenders for the supply of two 300-kw. three-phase generators, 5,500 volts, to be coupled to existing Belliss engines, and two 300 kw. synchronous three-phase motors, 5 000 volts, to be coupled to existing multipolar Silvertown dynamos. Tenders by 28th inst. See advertisement.

Liria (Spain).—The Alcalde requires tenders for the public lighting by electricity of the town, in accordance with conditions which can be seen at the office of the Secretary of the Municipality. The total amount of candle-power required will be 2,000, and the basis of the contract will be an annual payment of 6,000 pesetas (about £175).

Philippopolis (Roumelia).—The Municipality requires tenders for a concession to construct and work electric lighting and tramways for 50 years. A guarantee of £6,000 is required. Tenders by Oct. 15. On the next day a second adjudication will take place in case there is an offer of £5 per cent. less per kilowatt-hour than the minimum.

Craiva (Roumania).—The *Moniteur des Intérêts Matériels* (Brussels) announces that the adjudication will take place at 4 p.m. on Oct. 25 (Nov. 7) at the Mayoralty of Craïova, of the concession for construction and working of a line of tramways (mechanical traction) in the town of Craïova. The duration of the concession is fixed at 50 years. A provisional deposit of £200 is required.

Aberdeen.—The City Parish Council invite tenders for the following works in connection with the new poorhouse at Oldmill: (1) electric light plant—engines, dynamos, etc.; (2) steam-boilers; (3) steam distribution and heating; (4) non-conducting covering for boilers, etc. Tenders to be lodged with Mr. C. B. Williams, inspector. Aberdeen City Parish Council, 20, Union-terrace, Aberdeen, by 12 noon on Oct. 19.

Antwerp.—The Municipality of Ghent invite tenders for the construction of 10 electric cranes at that port in accordance with the specification, a copy of which may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall street, E.C. An initial deposit of 2,000fr. (£80) is required to qualify each tender, and for the tender accepted a further deposit of 18,000fr. (£720). Tenders, in registered envelopes, addressed "Au Collège Echevinal de la Ville de Gand," must be posted not later than Oct. 17. The adjudication will take place on Oct. 19.

La Rochelle (France).—The Chamber of Commerce will shortly issue tenders for a crane with a lifting power for 30 tons. The beam, or the part which projects over the water or vessel alongside, should be long enough to unload from a point about 25ft. 6in. from the edge of the quay. The height of the distal end above the quay should be 15m. (49·21ft.); the vertical distance between the edge of the quay and that part of the crane directly over it, 8m. (26·4ft.). A locomobile is preferred, but should the conditions be unfavourable for installing such a machine, then a fixed crane would be adopted.

Brisbane.—Tenders are invited by the Deputy Postmaster-General for the supply and delivery at the Telegragh Office Yard, Thursday Island of 100 tubular wrought-iron telegraph poles to Specification No. 11 and Schedule No. 51, and also for the supply and delivery at the cable tanks, Thursday Island, of three nauts of submarine cable to Commonwealth Specification No. 8 (Queensland, No. 22) and Schedule No. 50. Tenders by Dec. 12. They must state the time required for delivery; this time will be counted from the date of the notification of the acceptance of the tender. Specifications and forms of tender can be obtained at the General Post Offices, Sydney, Melbourne, Brisbane, and Adelaide. Neither the lowest nor any tender will necessarily be accepted. Tenderers are required to note that Customs' duties must be included in all charges, as per clause 2 of the general conditions. All tenders sent by post must be registered.

RESULTS OF TENDERS.

Airdrie.—The School Board have accepted the tender of Mr. Grant, South Bridge-street, for fitting up four electric clocks at £18 each.

Lifts.—Messrs. Wm. Aug's Gibson, Limited, 28, Fleet-street, E.C., have obtained the contract for the lifts for the new Shipping Exchange buildings in Cockspur-street.

Exeter.—The tender of Mr. W. Blake, Plymouth, at £4,265, for the superstructure for the tramway car shed has been recommended for acceptance.

Aston.—The Electricity Committee have accepted the tender of the General Electric Company, Limited, for the supply of a steam generator and plant at the price of £1,529.

Battersea.—The Borough Council have accepted the offer of the British Thomson-Houston Company, Limited, for 70 improved prepayment electricity meters for the Latchmere Estate at the rate of £5 each.

Greenwich.—The London County Council have received the following tenders for the transforming plant required for the temporary provision of electric current for power purposes to the electricity generating station:

Electric Construction Company, Limited, London and Wolverhampton*	£860
Johnson and Phillips, London	860
British Electric Plant Company, Limited, Alloa, N.B.	940
Lancashire Dynamo and Motor Company, Limited, Manchester	1,034
British Westinghouse Electric and Manufacturing Company, Limited, London	1,083

* Recommended for acceptance.

Newcastle.—The Union Electric Company, Limited, 151, Queen Victoria-street, E.C., have received the order for the supply of all the arc lamps required for the illumination of the industrial exhibition.

Digitized by Google

The Excello intense flame arc lamp has been adopted, as being the most suitable for this class of work.

Watford.—The Urban District Council have accepted the tender of Messrs. Clifford and Gough, at £3,745 for additions to the electricity works. The committee have also placed an order with the Brush Electric Company, Limited, for a new engine at a cost of £130.

BUSINESS NOTES.

TRACTION.

Maidstone.—Tramway extensions have been decided upon.

Warrington.—The Town Council decline to institute ½d. fares.

Colchester.—The Corporation has rejected the proposed extensions as premature.

Southend-Colchester.—The Board of Trade have sanctioned a light railway between these places.

Birmingham.—It is reported that the Harborne route is to be abandoned on account of the objections of the residents.

Wigan.—Owing to the Hindley Council insisting upon terms which the Corporation consider unreasonable, that route has been omitted from the tramway scheme.

Falkland.—The residents are considering the question of introducing a light railway. The county surveyor has been requested to prepare plans and estimate.

Coventry.—The residents of Earlsdon having requested the company to vary the proposed routes, the company have promised early consideration of the matter.

Pudsey.—In reference to the proposed tramway service, the Corporation have retained the services of Mr. E. J. Silcock, M.I.C.E., F.S.I., of Leeds, to prepare plans and advise them generally on the question of tramways.

Accrington.—The Clayton District Council have resolved that the Corporation be asked to include certain additions and alterations in their Bill respecting tramways, and also a clause giving the Council power to supply energy for traction within their district.

Northampton.—At the meeting of the Town Council the chairman of the Tramways Committee made an encouraging speech as to the income of the undertaking since the electrification of the system, and added that if the committee could reasonably do anything in the way of workmen's tickets they would.

South Shields.—After a three-night debate the Council have decided upon municipalisation in regard to the tramways. A considerable section of the Council favoured a proposal that after constructing the lines the authorities should invite tenders for a lease, but ultimately the above decision was arrived at.

Pontypridd.—The portion of the tramway from Hafod to Porth has been purchased by the Rhondda District Council, and the Pontypridd Council decided to ask that authority to appoint a committee to meet representatives of the Council with a view to making arrangements for the working of the tramways as far as Porth.

Bournemouth.—It is anticipated that the work of constructing the new tramway from Bournemouth to Christchurch will be put in hand at an early date. The Corporation, with this object in view, have purchased the Tuckton Bridge, which has for several years been used for vehicular and pedestrian traffic over the Stour, at £15,000.

Liverpool.—The City Council have approved the recommendation of the Tramways Committee that application be made for powers to construct two tramway routes in Bootle. The Local Government Board will hold an enquiry on the 20th inst. into the application of the Corporation for a loan of £400,000 in connection with the extension scheme.

Dumbarton.—Two companies are suitors for the privilege of providing tramways for the district, but the Council are considering the question of undertaking a service themselves. Something may depend upon whether the Electric Supply Corporation can obtain the consent of the adjoining authorities. If they can, it is probable that the Council will come to an arrangement with them.

Notts and Derby Tramways Co.—The company having asked the Mansfield Woodhouse Urban District Council for approval of the proposed position of the rails and poles, the Council have suggested that where the widening of the road is necessary to obtain 22ft. of metalled roadway, in accordance with the Board of Trade regulations, the company should increase the width to 36ft., including footpath.

Baker-street and Waterloo Railway.—The subway from the eastern side of the booking hall at Charing Cross Station to the footway in front of the Strand post office is being proceeded with. The hoarding has been removed to centre of roadway in order that the work in the new section can be carried on. The work on the proposed subways leading to Northumberland-avenue and Charing Cross is not being proceeded with pending the negotiations for an alternative subway at Cockspur-street.

Rowley.—The work of constructing the new tramway from Oldhill to Blackheath, which was undertaken by the District Council at a cost of £28,000, has now been completed, and the line has been connected up with Dudley and Cradley Heath. Power will be supplied by the British Electric Traction Company, which has secured the lease of the tramway. The inspection by the Board of Trade will probably take place in the course of the next few days.

Derby.—The Corporation have approved the proposal of the Tramways Committee to establish an insurance fund against third-party risks. The sum of £1,000 from the proceeds of the accumulated revenue of the tramways is to be placed to the credit of a reserve fund, to which will be contributed £10 in respect of each car per annum. On the question of extensions, a councillor suggested that before further extensions were considered the committee should give their attention to the question of motor 'buses, which would obviate expenditure upon the permanent way.

Chatham Light Railway.—There has been some discussion between the company and the Gillingham Town Council with reference to the refusal of the company to run all cars to the terminus at Gillingham Green. The Council appealed to the Board of Trade, who requested the Council to state what they would consider an adequate service. Particulars of the service desired by the Council have been forwarded to the Board. As the Board cannot approve By-laws 8 and 9, it is proposed to hold a conference with the Chatham Corporation so that a form of by-law for preventing overcrowding may be agreed upon.

Swansea.—At a meeting of the Tramways Committee, the surveyor reported in regard to the work of extension that out of 10¼ miles rather less than 3¼ remained to be completed. The committee deputed the chairman, vice-chairman, and engineer to meet the Education Committee with a view of creating a scholarship scheme, and giving boys who had won a scholarship at the technical college an opportunity of becoming pupils at the electric station. The tramways company state that they cannot see their way to expend £427 extra on wood paving at St. Thomas. The directors, however, agree to use wood paving outside the two chapels for 40 and 32 yards respectively. It has been decided to ask the company whether they will take over and work the tramway sections as they are completed.

Bury.—At the meeting of the Town Council the Chairman of the Tramways Committee stated that the tramway system had been completed within the borough, and cars were running before the date fixed for the completion. He quoted figures showing that the Council in undertaking the construction themselves had accomplished the work of permanent way, electrical equipment, and street improvements at a cost of £144,000, compared with an estimate of £204,000. He paid a high tribute to the borough electrical engineer (Mr. A. W. Bradley) and to the working staff for the admirable manner in which the work had been conducted. In regard to workmen's fares, it has been decided that the system of issuing books of tickets should be abolished, and that from the first car in the morning until eight o'clock tickets for the return journey will be issued at single fares.

Glasgow.—The Corporation have adopted a proposition that the general manager be instructed to make up a statement showing separately each week, for the next two or three weeks, the revenue and earnings per car mile run of the routes outside the city. A report by Mr. Young showed that by taking the earnings for the 12 months to Aug. 20 last on those routes which have one or both termini outside the city boundaries, it is found that the average revenue works out at 10·74d. per car mile, and by taking the earnings on those routes which may be termed city routes the average revenue for the year works out at 10·51d per car mile. "The above result," observes the report, "shows that the outside routes from end to end give an average of about ¼d. per car mile more revenue than the inside routes." The scheme of extensions was approved, except in regard to the Riddrie to Hogganfield route.

London County Council.—It is reported that the City Corporation are now disposed to view the Council's scheme for a tramway along the Embankment more favourably, though no official communication has yet taken place. The Council have replied to a letter from the St. Pancras Borough Council, in which the latter require the conduit system to be used throughout their district. The Council state that they have endeavoured to arrange for the conduit system in the more central districts, overhead traction being as far as possible confined to the outlying areas. It is added that the estimated additional outlay which would be involved by the substitution of the conduit system on those routes for which it is suggested that the overhead system should be employed would amount to something like £500,000. A special committee of the St. Pancras Council recommend the latter to adhere to their resolution requiring adoption of the conduit system throughout.

Perth.—The Town Council had under consideration on Saturday a resolution of the Tramway Committee not to proceed at present with the electrification of the tramways. The Lord Provost opposed the electrification proposal, and thought that more horses and cars would meet the requirements of the town. The Dean of Guild moved that the offers for electrification be accepted. These amounted to £32 862. 14s. 2d., besides which provision must be made for engineers' fees and the wages of the clerk of works. Adding the purchase price, the capital expenditure would amount to £68,292, or, say, £70,070. He reminded the Council that the borrowing powers under the Tramways Act and under the order obtained last year were £77,000. The present time was favourable to the economical execution of the work. One councillor moved that the tramways be leased to a company, and another that a *plébiscite* should be taken. Eventually the subject was deferred until the next meeting.

Rochdale, Bury, and Oldham.—Mr. James More, the valuer for the local authorities in connection with the tramways arbitration, has withdrawn his first allocation of the purchase price of the company's undertaking, and has sent another apportionment. It appears that the original allocation did not comply with Clause 2 of the agreement between the local authorities. The revised award, which differs but slightly from the original one, is as follows: Rochdale and Wardle, £70,790. 6s.; Littleborough, £6,979. 18s; Royton, £15,421. 14s.; Heywood, £20,239. 7s. 2d.; Bury, £38,394. 15s. 9d.; Tottington, £4 134. 18s. 2d.; Unsworth, £3,016. 12s. 4d.; and Whitefield, £3,697. 8s. 7d. In connection with the completion of the purchase, fixed for yesterday, a curious position is reported to have arisen. The agreement provides that in the event of the transfer not being carried out by the appointed date, the authorities shall pay interest at the rate of 5 per cent. The authorities were ready with the purchase-money, and were willing to give an undertaking to pay the company's

Digitized by Google

costs after taxation; but it is stated that the company were not disposed to accept an undertaking. Seeing that the authorities are only liable for the taxed costs, it is not easy to see how they can pay same before the bill has been before the taxing master, unless the company expect them to hand over an ample sum for same on completion, leaving the final settlement until the bill has undergone taxation.

Belfast.—A joint meeting of the Finance and Tramways Committees was held on Monday, when a long discussion was held in regard to the financial aspect of the Belfast Street Tramways undertaking, and finally it was decided that a sub-committee, consisting of the Lord Mayor, the chairman of the Finance Committee, the chairman of the Tramways Committee, and the chairman of the Law Committee, should take this matter into consideration, have an interview with the bankers, and, if necessary, visit London, and subsequently submit a report to an adjourned meeting of the two committees. Subsequently, at a meeting of the Tramways Committee, it was reported that the consulting engineers, Messrs. Lacey, Sillar, and Leigh, are to forthwith make a careful inspection of the whole system and prepare a report, and it is expected that they will meet the Tramway Committee to-day. A long report was submitted by the general manager bearing upon the amalgamation of the tramways and electric lighting undertakings. Mr. R. Brown, of the Kingsland mechanical surface-contact system, wrote to the effect that he was prepared to instal that system for several miles in any part of the city the committee chose for the purposes of a free trial, and if at the end of the trial the committee were not satisfied with it he would remove it and replace that portion of the line with the overhead traction. A reply was sent to Mr. Brown to the effect that the committee were still considering the matter. It is proposed to retain Mr. Balfour Browne, K.C., and the Irish Solicitor-General for the arbitration with the company.

Heywood.—The Tramway Committee held a meeting last week to consider the replies from Bury and Rochdale to the suggestion of Heywood on the question of payment for working the cars within Heywood borough. At the joint conference the representatives of Bury and Rochdale suggested that 5d. per car mile should be paid. Heywood's representative did not agree with this suggestion, and subsequently, by the direction of the committee, the town clerk of Heywood wrote to both the neighbouring corporations offering to pay 4½d. per car mile, and giving reasons why it was considered that this was sufficient. It was further suggested that if Bury and Rochdale could not accept this offer, the matter should be submitted to the arbitration of some practical tramway manager to fix the sum to be paid. Both the corporations replied to the same effect that they had carefully considered the matter, and could not agree to depart from the 5d. per car mile suggested. They offered, however, to make the agreement retrospective at the end of 12 months, and if the working expenses proved to be less than 5d. per mile, then Heywood would be given the benefit, and the price to be paid for the next five years would be fixed at the amount agreed upon as the working expenses for the 12 months. After considering the question, the committee decided that they would agree to pay the actual working expenses as found by each year's working. At a meeting of the Finance and General Purposes Committee resolutions were adopted authorising the borrowing of the money from the bank for the payment of Heywood's portion of the award for the buying out of the company. The amount due from Heywood is £20,239. 7s. 2d.

LIGHTING AND GENERAL.

New Cable Works.—New cable works are about to be established at Ammendorf, near Halle.

Derby.—The Corporation have reduced the maximum price for current from 5d. per unit to 4¾d.

Neath.—An enquiry has been held into the proposed borrowing of £20,000 for electric lighting purposes.

Wolverhampton.—Sanction has been received to the borrowing of £10,000 for the purpose of electric lighting.

Doncaster.—The Town Council have agreed that places of worship be charged at the uniform rate of 3½d. per unit.

Dudley.—In the last eight weeks 234,043 units were generated, of which the trams took 148,839, public lighting 10,348, and private lights 52,671.

Holloway.—In order, it is stated, to obviate the possibilities of suicide by gas, the electric light has been installed in 400 cells in Holloway Goal.

Blackburn.—It is proposed that when a successor to Mr. Giles has been appointed he should combine the offices of electrical engineer and tramways manager.

Indo-European Telegraph Co.—The directors have declared an interim dividend for the half-year ended June 30 last at the rate of 5 per cent. per annum.

Sunderland.—An enquiry will be held on the 18th inst. into the application of the Corporation for sanction to borrow £25,000 for electric lighting purposes.

Buralem.—The Town Council have appointed a deputation to confer with the Tunstall Council with regard to the supply of electricity in bulk to the latter authority.

Tonbridge.—A largely signed memorial, asking, amongst other things, for more light, has been referred to the Highways Committee of the Urban District Council.

Crewe.—The Town Council have recommended the acceptance of several tenders, amounting to some £4,000, for additional machinery and equipment at the electricity works.

Sligo.—The General Post Office authorities are at present considering a scheme whereby intermediate towns on the route between Dublin and Sligo may be provided with telephone facilities.

Walsall.—The electrical engineer has been instructed to report the estimated cost of extending the mains in Lysways-street and Pershore-street, and the probable consumption and income.

Paisley.—The Town Council have accepted the suggestion of the electrical engineer, Mr. Parkinson, to approach Johnstone and Renfrew Corporations with a view to the supply of electricity to these towns.

Telephones over the Thames.—The Thames Conservancy have granted permission to the National Telephone Company, Limited, to stretch two additional wires across the river below Staines railway bridge.

Portsmouth.—Application is to be made for sanction to borrow £635 for telephone extension. There are now 1,935 lines fixed, and at the next meeting it will be proposed to extend the proposed loan to £1,200.

Removals.—The Civil and Mechanical Engineers' Society has changed its offices to 25, Victoria-street, Westminster. The Linolite Company have moved into larger offices at 25, Victoria-street, Westminster.

Sale of Plant, etc.—Particulars of a sale of a complete electric lighting plant by W. P. Adams, 28, Victoria-street, Westminster, S.W., appear in another column, also of a lease of an equipped warehouse at Chelsea.

Aston.—The hours of "peak charge" have been altered to between 6 p.m. and 8 p.m., and consumers are now given the option of an alternative flat rate of 4d. per unit, with a discount of 5 per cent. if accounts are paid within one month.

Kensington.—The following notices of intention to lay mains have been agreed to: Notting Hill Electric Lighting Company in Ladbroke-grove, Clydesdale-road, and Westbourne-grove; Brompton and Kensington Electricity Supply Company in Warwick-street.

Whitwell.—The Derby County Council have sanctioned the application of the Parish Council to raise a loan of £2,000 for the purpose of lighting the parish by electricity, preparatory to the matter coming before the Local Government Board in the ordinary way.

Darlington.—Current is now supplied for tramway purposes at the following charges: for the first 1,000 units, 4½d. per unit; for the next 2,000 units, 4¼d. per unit; and for over 3,000 units, 4d. per unit. This is a reduction of ½d. per unit all round, which is equal to 10 per cent.

Anglo-American Telegraph Co.—The directors have resolved, after placing £5,000 to credit of the renewal fund, to declare an interim dividend for the quarter ended Sept. 30, 1904, of 12s. 6d. per cent. on the ordinary stock and £1. 5s. per cent. on the preferred stock.

London County Council.—On Tuesday the Council agreed to sanction a loan of £23,960 to the Stepney Borough Council for electric light installation and meters. A number of applications to lay mains under Electric Lighting Acts and Orders in the Metropolis were agreed to.

Stretford.—The total units generated during August was 78,007, of which 49,520 were used for power and 14,460 for lighting. The revenue for the past month was as follows: traction, £309. 10s.; public lighting, £132. 16s. 11d.; private lighting, £60—total, £502. 6s 11d.

Carlisle.—Sanction has been received to the borrowing of £5,000 for the purposes of main extensions, meters, services, etc., the whole to be repaid in 25 years. The agreement with the North British Railway Company for the electric lighting of the canal goods yard by electricity has been completed.

Westminster.—The St. James and Pall Mall Electricity Company have now changed the arc lamp globes in their district from muranese to opalescent, with a very decided improvement to the lighting of the streets. This alteration, previously approved by the Works Committee, will not entail any increased cost to the Council.

St. Pancras.—The Borough Council support the proposed application of the London County Council to Parliament for powers to enable the local authorities who are or who may hereafter become electric lighting and power undertakers to wire and fit consumers' premises for the use of electrical energy, and to obtain loans for this purpose.

Easedon.—The Urban District Council have accepted an offer of the Backworth Coal Company to supply current for 100 lamps in the principal roads and streets of the Easedon and Backworth Wards. The cost will be slightly higher than they were paying in the Holywell Ward, but there is a possibility of a reduction after the project is completed.

Upton and Prenton.—Sanction has been obtained to the borrowing of £6,500 for the purpose of supplying electricity in Prenton and Upton. The town clerk is about to give the necessary statutory notices in respect of the laying of electrical cable from the borough into the township of Prenton. Current will be supplied in Upton about Nov. 15.

Finchley.—The estimates of the Electric Lighting Committee for the coming half-year show that a sum of £2,719 will be required, with receipts at £2,715. There would be an estimated deficit of £4. The committee does not anticipate that it will be necessary to make any call on the rate for the coming half-year. Up to date 14,100 8-c.p. lamps have been applied for.

New Barnet.—On Tuesday the Urban District Council were asked to receive a deputation of ratepayers on the subject of electric lighting. It was decided to inform the deputation that arrangements in connection with the scheme were not sufficiently advanced to admit of immediate settlement, and that consequently there would be ample time for holding a public meeting or meetings for the purpose of considering the Council's scheme.

St. Marylebone.—The Council last night received a report on the financial side of the proposed loan for the electric light recommending

Digitized by Google

that the town clerk be authorised to take all necessary steps in connection with the completion of the loan, and to affix the common seal to any necessary authority for the County Council to pay the sum of £1,415,000 to the Council's treasurer.

Gillingham.—The engineer in his last report states that the eqtivalent of 236 8-c.p. lamps had been connected with the mains since the last meeting, making a total of 11,815 8-c.p. lamps with 139 consumers connected. A number of three-light ½-ampere Lunar Nernst lamps are to be erected, also a 260-c.p. single-light fitting, and a main is to be extended. It is proposed to reduce the meter rents from 2s. 6d. to 1s. 6d. per quarter.

Pontypridd.—The General Post Office authorities have not found enough telephone subscribers at Llantwit Vardre to justify the expenditure involved in the establishment and maintenance of an exchange there. The District Council are now enquiring whether they would establish and maintain an exchange there if the Council contributed, in addition to the ordinary rate, a sum that would justify the necessary expenditure.

Transfer of Business.—Messrs. Robson and Coleman (late Robert Robson), electrical engineers, 5, St. Mary's-place, Barras-bridge, Newcastle-on-Tyne, have taken over the business of Mr. Thompson Gradon, jun., electrical engineer, 131, Barras-bridge, Newcastle-on-Tyne. We are informed that up to date over 2,000 electric light and power installations have been completed by that firm. They undertake all kinds of work, and a special repair department is one of their features.

Swindon.—The electrical engineer's last monthly report showed 234 consumers connected, as compared with 93 in the corresponding month of last year, and 152 street lamps, as against 65 a year ago. The extensions required to the generating station, in order to meet the demand for current for lighting and power purposes, have been approved. Plans will be prepared and application made for sanction to borrow £20,000. A number of electric mains are also to be extended.

Battersea.—The Lighting Committee have granted permission to the Association of Engineers-in-Charge to visit the central electric generating station on a Saturday afternoon to be arranged. An expenditure of £125 has been agreed to for fitting up the meter-testing room at the central electric generating station and the provision of cables, tools, and apparatus for the purpose of testing meters and carrying out the necessary works of repair which at the present time are being carried out by the meter-makers.

Hebden Bridge.—The Urban District Council's electricity works, costing £10 260, were opened on the evening of the 6th inst. by Mr. Abraham Webster, chairman of the Council. The scheme has been carried out under the advice of Mr. Walter Emmott, consulting electrical engineer, Hebden Bridge. The works consist of engine-room, storage-battery room, offices, and stores. Various commercial applications of electricity, with special references to its uses for motive power, were exhibited in the building.

Ilkeston.—An exhibition of electrical plant, inaugurated by the Tramways and Electricity Committee of the Corporation, was formally declared open on Monday by the Mayor (Alderman C. Maltby) in the presence of a numerous assembly, including Alderman Robinson (chairman of the Tramways and Electricity Committee), Councillors F. Woolley, W. Richards, and W. Shakspeare (members of the committee), Aldermen F. Beardsley and R. Hunt, Messrs. Hamilton (Nottingham), A. C. Gilbert (tramways manager), etc.

Ealing.—The financial result of the June quarter's trading of the electric lighting department is an increased income of 11 per cent. over the corresponding quarter of last year, but on account of a large increase in coal costs and extra interest, etc., the net result was more unfavourable than last year. During the vacation 2,342 lamps were applied for, making a total of 20,905. There are now 2,125 consumers on the books. The pressure at West Ealing requiring strengthening, a transformer station was recently built at West Ealing.

Tunbridge Wells.—The Lighting Committee have received a letter from the Southborough Urban District Council stating that their Highways Committee are of opinion that the Tunbridge Wells Corporation should bear the whole cost of the lighting of Powder Mill-lane. The committee consider that the arrangement made in 1897 is an equitable one, and should be continued. The further consideration of questions relating to transformers at private houses has been deferred, also consideration of a report by the electrical engineer upon the system of charging for current.

Carnarvon.—The draft free wiring agreement (already referred to by us) has been sealed. The following alterations have been made: (1) the Council to exercise their right of refusing applications for free wiring within six days instead of three days; (2) a clause to be inserted providing that a statement showing the prime cost of each installation be submitted to the Council quarterly; (3) the clause prohibiting the local authority from contracting with any other firm for the wiring of consumers' premises not to apply when the local authority are themselves the consumers.

Dumbarton.—Negotiations are still proceeding with the Caledonian Water Power Electricity Company, who have asked for wayleaves under the county roads for a period of 50 years. The Road Board, however, are only disposed to grant a wayleave during pleasure, as in the case of wayleaves for other purposes. There are also other minor difficulties, such as that of entering into an agreement, especially for a period of years, with an unincorporated company. On the other hand, the Board are anxious, if possible, not to interpose difficulties in the way of what might prove a public advantage.

London Gazette.—A general meeting of the members of the Stewart Electrical Syndicate, Limited, will be held at 140, Leadenhall-street, E.C., on Nov. 17 at 12 o'clock noon, to receive the liquidator's report showing how the winding-up of the company has been conducted and its property disposed of. A general meeting of the shareholders of the Electrical Indicator Syndicate, Limited, will be held at 4, Pembroke-street, London, N., on Nov. 15 at 11 o'clock p.m., to receive the liquidator's report showing how the winding-up of the company has been conducted and its property disposed of.

Yarmouth.—The half-yearly estimate of the Electric Light Committee anticipates a clear profit of £1 018. Another cable under the harbour has been broken. There were originally 20 cables, of which 16 have been broken, and of the four remaining two are in a very bad state. It has now been decided to lay six cables across the harbour in a steel tube, as was done for the tramways, at a cost of about £1,200 inclusive. There are now connected to the mains 546 consumers, representing 27,348 8-c.p. lamps. During September ten new consumers were connected, representing 339 8-c.p. lamps.

Wellingborough.—At the last Council meeting the Clerk read petitions from owners and agents of property in the immediate neighbourhood of the electric lighting works complaining of the vibration and noise caused by the working of the machinery at the works. It stated that several tenants had left the houses owing to the nuisance, and the owners were suffering pecuniary loss. A petition was also read from occupiers complaining of the humming noise, and alleging that the smoke nuisance had not been abated. Subsequently the Council sat *in camera* to meet the representatives of the electric company.

Erith.—The committee have accepted the resignation of Mr. P. M. Hunt, assistant engineer, and applications for the appointment are invited. The concrete foundation for a further boiler is to be put down before the present extensions to the generating station are completed. Messrs. Friday and Ling, the contractors, are to carry out this work at their schedule price (£60). Messrs. Callender's intend to use a part of the further supply of current demanded by them for the lighting of arc lamps at their works, and the Council have informed them that they cannot agree to supply current for arc lighting at the power rate of 1½d. per unit, but would be prepared to supply such current through a separate meter at the ordinary lighting rates.

Hastings.—At the last Council meeting a report was received from the Electric Lighting Committee with regard to the proposed loan of £3,416 for electric lighting purposes. It appears that the Local Government Board have drawn the attention of the Corporation to the fact that the deficits on the working of the undertaking during 1900 and 1903 have only partly been provided for. The Board wanted to know what steps the Council were going to take to wipe out the balance and to prevent a recurrence of these losses. The committee recommended that, in addition to the £1,500 provided for the purpose in the present estimates, a similar sum be set aside yearly until the deficit has been wiped out, unless in the meantime increased profits might render such provision unnecessary.

Manchester.—The Electricity Committee on Wednesday discussed the report of the chief engineer (Mr. Pearce) on the results of the experiments which have been made in lighting certain parts of the city with electricity. The details of the report were not disclosed, but the *Manchester Guardian* understands that the committee are satisfied with the results which have been obtained. All the old types of lamp have been exchanged for the Gilbert enclosed type. This new and better type of lamp will burn for 120 hours—some say for 150 hours—without needing retrimming or any attention whatever. The new lamps give a light equal to between 1,300 and 2,000 candles, whilst the illuminating power of the discarded lamps did not exceed in any case 1,000 candles. The lamps also required retrimming after every 20 or 30 hours of burning. At the close of their meeting in the town hall the committee went out to see the effect of the electric lighting in Piccadilly, Albert-square, and St. Ann's-square. The new lamps are certainly a marked improvement on the old ones.

Swansea.—An enquiry has been held into the Corporation's application to borrow £2,000 for extensions of the Corporation's telephone system. The Town Clerk said that £20,606 had been already sanctioned for the municipal telephone exchange, out of which £19,158 had been expended. At present there were 1,005 subscribers' instruments and lines, and the rentals were £3,823. 10s. 5d. The present application was to enable the Corporation to join up 176 further subscribers who had applied. Mr. Bennett stated that the total length of junction poles erected was 13¼ miles, leaving 18½ miles still to do. Capital remained unexpended sufficient for this purpose. The 1,005 lines in existence had cost £15,769, or only £15. 14s. 6d. each. At the last Council meeting the engineer reported that applications were being continually received with regard to the taking on of pupils at the electricity works, and the engineer reminded the committee of a former minute to the effect that the question "might be considered in the light of scholarships in connection with the scheme to be prepared under the Education Act, 1902." If it was the wish of the committee that pupils should be taken on, the engineer suggested that not more than three should be appointed, that the term should extend for two years, subject to a satisfactory scheme being drawn up jointly by the Education Committee and the Electric Lighting Committee. It was decided to appoint a small committee to confer with the Education Committee and ask them to carry out the suggestion, which had previously been carried. Mr. Pruemann reported that he had again been asked to extend the electric mains should be extended to the Sketty district, and it was decided to lay pipes when the cable work is done. The engine and dynamo to be removed from the Strand station to the destructor works in order to be suitable for tramway purposes, will require certain necessary alterations. Messrs. McLaren, of Leeds, made the engine, and they required £608 for the work, including dismantling and re-erecting. The rewinding of the dynamo would cost a further £152. It was decided to have specifications drawn up, and to invite tenders. The engineer has been requested to report upon the advisability of charging a flat rate.

Scottish Central Electric Power Co.—A start has now been made with the work connected with the erection of an extensive station by the Scottish Central Electric Power Company, who some time ago were granted a provisional order for lighting and motor purposes. About five acres of ground have been staked off at Carmuirs, between Bonnybridge and Larbert, and it is expected that the company's radius of supply will extend to about 12 miles. The engineers for the generating apparatus are Messrs. Bramwell and Harris, London, and the builders are Messrs. J. J. and P. McLachlan, Larbert.

Barrow.—An enquiry has been held into the borrowing of £35,000 for the purpose of electric lighting. The Town Clerk (Mr. C. F. Preston) said the electric lighting borrowing powers up to March had been £78 575, and the whole of that had been expended. The outstanding debt was £67,496. The borough rate for the year amounted to 4s. 3d. and the poor rate 1s. in the £, making a total of 5s. 3d. in the £ for the year. The proposed expenditure of £35,000 was made up as follows: buildings, £4,000; engine-room plant, £5,750; boiler-house plant, £6,750; clerk of works and contingencies, £1,500. This made the cost of the present extensions £18 000, and for additional services for the future they had put another £5 000. The borrowing powers applied for, but not obtained, amounted to £12,097, which made a total of £35 097.

Heston and Isleworth.—The Council are advertising that they will supply electric current for light and power at the following charges: lighting. 5d. per unit for any quantity, subject to the following discounts if accounts are paid at Council's office within one month from demand: winter quarters, consumption exceeding 200 units, summer quarters 150 units, 5 per cent. discount; 300 and 200, 7½; 400 and 300, 10; 600 and 350, 15; 700 and 400, 20. Meters from 1s. per quarter. Power: consumption not exceeding 750 units per quarter, 3d. per unit; consumption exceeding 750 units per quarter, 2d. per unit. Meters from 2s. per quarter. Premises will be wired and fitted on receipt of approved applications free of all initial cost to the consumer. In these cases current will be supplied at 5½d. per unit. The consumer will have the right of purchasing the installation outright at any time.

Ripon.—The Gas and Electricity Committee have been considering a letter from Mr. G. F. Metzger, of Manchester, to Mr. G. Simpson, South Lodge, respecting electricity for the city of Ripon, and also a report by Mr. Warden Stevens, of London, on a scheme to supply Ilkley with electricity. The Mayor, in thanking Mr. Simpson for his kindness in sending the letter for the perusal of the committee, stated that they were not prepared to go fully into the matter at present. A deputation of the Corporation has been received by Mr. Pelham, one of the secretaries of the Board of Trade, with reference to the electric lighting order of the city, and Mr. Pelham informed them that nothing would be done with respect to the order before next March, and that the Corporation should have an opportunity of laying their case before the Commissioners, when the Power and Traction Company applied, and suggested that the Corporation should make terms, if possible, with the company.

Middlesbrough.—The engineer (Mr. H. M. Taylor) in his last report states that during the month of September 58,798 units were sold, against 37,773 units in September last year, making an increase of 56 per cent. This result is largely due to the increased motor load. The revenue for the month amounted to £817, compared with £645 last year, and the cost of generation was £274, against £214. or 1·12d. per unit, against 1·36d. The total cost of production was £420, against £370, or 1·71d. per unit, compared with 2·35d. in September last year. This gives an estimated profit for the month of £396, exclusive of interest and redemption. The lamps connected during the month numbered 2,234, bringing the total lamps connected and applied for to 51,250, of which 45·4 per cent. had been burning at one time, the maximum load being 698 kw., compared with 619 in September last year. The extensions at present in progress will entail an expenditure estimated at £7,997, but a contract has been let at £7,772. At the conclusion of the last Council meeting, Councillor Hornung complimented Mr. Taylor upon the manner in which the electric light had been installed in the town hall.

Fareham.—From the accounts of the electricity works for the year ended March 31 we note that the loans amounted to £12,251, of which £3,345 has been repaid. The total capital expenditure to March 31, of which £558 was spent last year, totals £12,287, of which £5,577 is accounted for under "lands, including law charges incidental to acquisition," and including the purchase of the undertaking, £258 for buildings, and £2,533 for machinery. The total receipts to March 31 on the capital account are given as £12,304. The expenditure out of revenue amounted to £1,062, and the receipts to £2,036, made up as follows: sale of current per meter at 7d. per Board of Trade unit, £1,328; public lighting, £655; rental of meters and other apparatus on consumers' premises, £43; charging accumulators, £10—leaving a balance to be carried to the net revenue account of £974. Of that amount £784 has been absorbed by interest on mortgage debt and instalments of principal of money borrowed, leaving a balance on the net revenue account of £190, which, together with the balance of £128 from the last account, brings the reserve fund account up to £318. The quantity generated was 98,619 units, of which 34,654 were sold for public lamps, and 45,213 to private consumers by meter—making a total of 79,867. The quantity used on the works was 4,688, making a total quantity accounted for of 84,555, and the quantity not accounted for 14,064. The number of public lamps is 27 arcs and 109 incandescents. The total maximum supply demanded is 72 kw.

Colliery Plant.—Messrs. Ernest Scott and Mountain, Limited, Close Works, Newcastle-on-Tyne, report a number of contracts, amongst them being a complete plant for the Dunston, Swalwell, and Garesfield Collieries, Limited, the power for which will be supplied by the Newcastle-on-Tyne Electric Supply Company, and the installation will consist of the complete equipment both for the surface and underground. On the surface there will be an electric winding gear fitted with three-phase motor capable of winding from a depth of 200ft., the motor being fitted with a special controller so that the speed of the winding can be varied and also run at a very low speed if necessary for the examination of the shaft, etc. In addition to the winding gear, the fan and also an endless rope haulage gear, which are placed at bank, are also electrically driven. The current is taken down the shaft by armoured cables, and at the shaft bottom a main shaft pump of Scott and Mountain's well-known three-throw type is to be fixed, this pump to deliver 1,200 gallons of water per minute against a head of 220ft. In the five-quarter seam another electrically-driven pump will be placed, this pump delivering 200 gallons per minute at a distance of 1,000 yards in-by. In the Brockwell seam two further sets of Scott and Mountain's pumps will be placed, each of these sets being designed to deliver 300 gallons each against a head of 105ft. This is probably one of the first instances in the United Kingdom where the whole equipment of the colliery will be electrically driven and steam entirely dispensed with, and the owners of the colliery are to be congratulated on their enterprise. Other contracts include engines, etc., for Messrs. Jas. Ross and Co., of the Phillipstown Oil Works, Linlithgow; Messrs. Bell Bros., Limited, Port Clarence: the Wigan Coal and Iron Company, Limited; considerable extensions to the electrical plant for the Tredegar Coal and Iron Company, Limited, which they put down about three years ago; and also coal-cutting machinery for Consett Iron Company, Backworth Colliery, Hamsterley Colliery, Thorncliffe Colliery, etc.

Dundee.—When electric light was installed in Dundee current was conveyed to the central area, first served through copper stripe laid in an underground porcelain trough. The extensions in the first instance consisted of insulated cables laid in iron piping. Last year the work of reconverting and relaying street mains was begun, and completed about six months ago. The cables in the iron pipes were withdrawn, and for them insulated cables laid in porcelain ducts and encased in bitumen became the carriers of the electric current. The copper strips—the oldest part of the system—were then used as feeders to convey the current to various distributing centres in the area of supply. Recently it was ascertained that the porcelain supports were decomposing by electric action, and the Corporation have resolved to do away with the copper strips, and in their place to substitute modern cables. This work will necessitate an expenditure of about £3,000. Against this has to be placed the sum which is derivable from the copper, estimated at £950. The ducts required are in stock. The *Dundee Advertiser* says the engineer, writing under date Oct. 4, states "that the lead sheathing of the cables which were laid in pitch in wooden trenches in the outlying areas of Dundee in the year 1900 has never been earthed—that is, the lead sheathing at carefully calculated intervals should be connected to the earth by water-mains or otherwise. This has been carefully and thoroughly done during the laying of the cables on the new system, and I anticipate that much damage will probably have been done to your outlying system through the work of earthing the lead sheathing of these mains having been omitted." The engineer, in explanation, added that the leakage currents which may have been allowed to leave their proper path of returning to the generating station will travel along water-mains and gas-pipes, doing damage to the same. This same damage in a worse way may happen to the lead sheathing of the cables, although by equalising the pressure at different points of the system—that is, by connecting the lead sheathing to water-mains at these points—it is possible to eliminate any trouble from this source. He further stated that he would take immediate steps to communicate with the original contractors, with the view of having the work done at once. Should any damage to the lead sheathing of the cables be discovered, especially as the tramways have been running during that period, it was quite possible that the stray currents from them (which at one time were high) had travelled along the lead sheathing of these mains to its detriment. It was impossible, Mr. Richardson said, to find out whether damage had been done or not at the present date.

PROVISIONAL PATENTS, 1904.

Oct. 3.

22440a/1903. Improvements in telephone switchboards. Wallace Cranston Fairweather, 65, Chancery-lane, London. (The Kellogg Switchboard and Supply Company, United States.) (Date applied for under Patents Rule 9, Oct. 17, 1903.) (Complete specification.)

21157. Improvements in electrical switches. Harry William Cox, Temple-buildings, Albert-street, Nottingham.

21170. Automatic trolley-pole adjuster for electric tramways. Walter Cecil Mantby Pettingill, 13, Mount Preston, Leeds.

21211. Method of regenerating negative accumulator plates of diminished capacity, or for avoiding the diminution in capacity of new plates. Richard Kieseritzky, 18, Southampton-buildings, Chancery-lane, London.

21217. Improvements relating to automatic telegraphic apparatus. Antoine Damaskinos, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

21222. Improvements in sockets or holders for incandescent electric lamps. The British Thomson Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Oct. 4.

21242. Improvements in and connected with electric arc lamps. Otto Gross, 5, John Dalton-street, Manchester.

Digitized by Google

21243. An automatic contact make and break for electric ignitions for gas and other engines. Harry Frank Rogers and Sidney Edmonds, 29A, Longmore-street, Birmingham.

21247. Electric automatic alarm letter-box opening. David Portman Corbet and William Mapp Hughes, 54, New-road, Kidderminster.

21259. Improvements in electric switches. Harry William Cox, Albert-street, Nottingham.

21264. Improvements in electric arc lamps. August Eckstein and Arthur Ernest Angold, Peel Works, Adelphi, Salford, Manchester.

21276. Improvements in means for supplying and collecting electric current for driving electric trains and other vehicles. Paul Trangott Julius Estler, 52, Chancery-lane, London.

21307. A new or improved electricity meter. Emile Julien Javaux, 18, Buckingham-street, Strand, London.

21310. Improvements in smelting furnaces and electric stoves. Walker Moseley, 23, Trossachs-road, East Dulwich, London.

21314. Improvements in electric phase indicators. Kenelm Edgcumbe and Edgar Isaac Everett, 151, Great Saffron-hill, London.

21315. Improvements in ground detectors and electric cut-outs. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

21322. Improved process for the etching of metal plates by the aid of electrolysis. Otto C. Strecker and Hans Strecker, 322, High Holborn, London. (Complete specification.)

OCT. 5.

21329. Improvements in electric trolleys. Thomas Cowburn, Rundle House, Hucclecote, Gloucester.

21332. An improved method for attachment for receivers of telephones and the like. Darcy Thornicroft, 32, Fernbank-road, Undercliffe, Bradford.

21334. Improvements in seats for use on electric and other cars, vehicles, ships, and outdoor purposes generally. Frederick Leese, 27, Waller-street, Byker, Newcastle-on-Tyne.

21340. Improved means for producing electric light. Charles Frederick Adams and Leonard Rowland Whitfield, 10, St. George's-crescent, Liverpool.

21382. A new or improved method of operating telephonic exchange systems, and apparatus therefor. Arthur Thomas Milnor Thomson and the Thomson-Davis Telephone System, Limited, Norfolk House, Norfolk-street, Strand, London.

21388. Improvements in electric measuring instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

21400. Improvements in and relating to electric traction systems. Alfred Cecil Eborall, 13, Southampton-buildings, Chancery-lane, London.

21401. Improved method of effecting communication between telephone exchanges, and apparatus therefor. Arthur Thomas Milnor Thomson, 22, Southampton-buildings, Chancery-lane, London.

21402. Improvements in electrodes for electric accumulators with invariable electrolyte. Ernst Waldemar Jungner, 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, Oct. 7, 1903, being date of application in Sweden.) (Complete specification.)

21403. A method for increasing the activity in electrode masses of badly conductive metallic oxides or hydrates in accumulators with invariable electrolyte. Ernst Waldemar Jungner, 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, Oct. 31, 1903, being date of application in Sweden.) (Complete specification.)

21405. Improvements in means for suspending overhead electrical conducting wires or cables. Anton Kuchinka, 18, Buckingham-street, Strand, London.

OCT. 6.

21409. A new or improved appliance for use in indicating the presence of electricity. George Charles Shankster, 26, Lee-street, Holderness-road, Hull.

21415. Improvements in the construction of electric tramways. Samuel Green Bennett, Clyde House, Heath Town, Wolverhampton.

21422. Improvements in electrical switches. Harry Nunns, South-parade, Halifax.

21423. Improvements in or relating to electric lamp bulbs. John Charles Barker and Frederic Claude Rylands, 100, Wellington-street, Glasgow.

21435. A device for covering and protecting the conductor or "live" rail of electric railways, and a current-collector arm to be used with the same. Oscar Sayle Gill, Lake House, Allerton-road, Woolton, Liverpool.

21447. Improvements in connection with electric railways. William Percy Nesbitt, 55, Chancery-lane, London.

21455. Electric time alarms. Samuel Sidney Bromhead, 33, Cannon-street, London. (The American Bank Protection Company, United States.) (Complete specification.)

OCT. 7.

21513. Improvements in the construction of electric accumulators. Jacques Marie de la Croix and Henry Francis Joel, sen., 74, Windsor-road, Forest Gate, London.

21519. Improvements in starting apparatus for electromotors. Charles Turnbull, jun., 34, Castle-street, Liverpool.

21523. Improvements in arc lamp mechanism. George Owen Donovan, 126, Chester-road, Erdington, Birmingham.

21532. Improvements in and relating to electric signs and illuminated devices. Francis Bertram Felloes, 60, Queen Victoria-street, London.

21543. Improvements in or relating to electric light fittings. William Winstanley Strode, 111, Hatton-garden, London.

21553. Improvements in galvanic dry cells or batteries. William Strickland, 21, Finsbury-pavement, London.

21562. Electrolytic method and apparatus for the production of white lead. Elias Bernard Koopman, 18, Southampton-buildings, Chancery-lane, London. (Clinton Paul Townsend, United States.)

21564. Improvements in pillar brackets for the control gear of electrical or other mechanism. Edward Neville Bray, Frederick Rice Markham, Ferdinand Edward Reiss, and Markham and Reiss, Limited, 18, Southampton-buildings, Chancery-lane, London.

21566. Improvements in the electro-deposition of copper and other metals. Sherard Osborn Cowper-Coles and the Metals Corporation, Limited, 4, South-street, Finsbury, London.

21567. Improvements in removing metallic cylinders from mandrels on which they are electro-deposited. Sherard Osborn Cowper-Coles and the Metals Corporation, Limited, 4, South-street, Finsbury, London.

21579. Improvements in electric meters and demand indicators. George Markham Hayton, 23, Coleman-street, London.

21580. Improvements in or relating to contact devices for electric clocks. Bernard Gustafson and Ragnar Carlstedt, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, Oct. 8, 1903, being date of application in Sweden.) (Complete specification.)

OCT. 8.

21601. Improvements in trolley sheaves for engaging electric power wires, applicable also to sheaves and guide pulleys used with wire ropes, cables, and the like. Silas Williams, Phœnix Foundry, Bute Docks, Cardiff.

21622. Improvements in electric ignition for internal-combustion engines and in apparatus therefor. Rankin Kennedy, Bute, Shettleston, N.B.

21625. Submarine cable groyne. Rowland George Allanson Allanson-Winn, 22, South Frederick-street, Dublin.

21629. Shade-frame for electric lamps, especially pear lamps. Gustav Adolph Lehmann, Seestrasse 5, Dresden, Germany.

21639. Improvements in electrical condensers. Marconi's Wireless Telegraph Company, Limited, Edgar Berry, and Harry Alexander Elrick Ewen, 24, Southampton-buildings, Chancery-lane, London.

21640. Improvements in apparatus for wireless telegraphy. Marconi's Wireless Telegraph Company, Limited, Edgar Berry, and Harry Alexander Elrick Ewen, 24, Southampton-buildings, Chancery-lane, London.

21641. Improvements in safety devices in connection with radio-telegraphic transmission circuits. Marconi's Wireless Telegraph Company, Limited, Edgar Berry, and Harry Alexander Elrick Ewen, 24, Southampton-buildings, Chancery-lane, London.

21642. An electrical apparatus for adjusting tramrail points. Joseph Edward Macaulay, 7, Eldon-terrace, South Circular-road, Dublin. (Complete specification.)

21648. Improvements in trolley heads employed in electrical traction. Horace James and Arthur West, 15, St. James's-row, Sheffield. (Complete specification.)

21672. Improvements relating to electric batteries. Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (La Société Anonyme le Carbone, France.)

21676. Improvements in electrodes, specially applicable to electric arc lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

21677. Improvements in electrodes specially applicable to electric arc lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

21678. Improvements in and relating to the construction of rotary members for dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Oct. 27, 1904.

1903.

21008. Mounting a number of electrical fittings or instruments upon a common base or panel. Hofstede-Orull.

21173. Electro-mechanical arrangement for changing speed and for reversing. Gasnier.

21318. Electric switch-holders or key switches. Davies.

21504. Electric meters. Soc. Anon. des Ateliers de Mécanique de Précision de Derritet. (Date applied for under International Convention, Oct. 15, 1902.)

21939. Signalling through submarine and like cables. Lodge and Muirhead.

21939a. Signalling through submarine and like cables. Lodge and Muirhead. (Date applied for under Patents Rule 9, Oct. 12, 1903.)

22216. Laying electric conductors. Tanner and Claremont.

22443. Apparatus for winding inductive and non-inductive coils. Wilson.

22551. Electric motors and controlling devices for use in the electrical propulsion of vehicles or trains of vehicles. Raworth.

24305. Means for the production of continuous high-potential electrical discharges, applicable for the deposition of dust, fume, smoke, fog, and mist for the production of rain, and for other purposes. Lodge.

24469. Suspending chain for electric lamps and the like. James Hinks and Son, Limited, and Wright.

24472. Electric furnaces. Ruhstrat and Grimmer.

24793. Fluid pressure regulators. British Thomson-Houston Company, Limited. (General Electric Company.)

24796. Moter controllers and emergency brakes for railway and tramway vehicles or trains. British Thomson-Houston Company, Limited. (General Electric Company.)

25006. Electric ignition apparatus for internal-combustion motors and the like. Lewis and Daimler Motor Company, Limited.

25387. Controllers for regulating the speed of electric motors. Scott.

26267. Electric measuring and recording devices. Atkinson.

26268. Electrolytic meters. Atkinson.

26456. Insulated electric conductors. British Thomson-Houston Company, Limited. (General Electric Company.)

26457. Insulated coils for electrical apparatus and process of making the same. British Thomson-Houston Company, Limited. (General Electric Company.)

26460. Electric rheostats. British Thomson-Houston Company, Limited. (General Electric Company.)

26462. Electric arc lamps. British Thomson-Houston Company, Limited. (General Electric Company.)

26577. Field magnets for dynamo-electric machines. Finzi.

27189. Means for controlling the voltage from an electric generator. Deutsch.

27283. Counters for electric current meters, gasmeters, water-meters, and the like. Biermann.

1904.

1374. Method of and means for regulating electric motors. Lang.

6110. Electric arc lamps. Foster, Grote, and Ely.

6411. Brush-holders for electric motors or generators. Cooch.

7249. Electrical fuse boxes, junction boxes, and the like. Lee.

8745. Trolley pulleys of electric tramcars. Binns.

12766. Apparatus for gripping or holding and cutting submarine cables. Sazérat.

14059. Apparatus for electro-galvanising. Potthoff.

14060. Conductor and collector devices for electric railways and tramways. Bolzano.

16395. Combined electric switch and lamp-holder. Hunter.

16578. Morse telegraph transmitters or instruments for transmitting telegrams by means of Morse signals. Wolters.

17051. Electrical switches, known as tumbler switches. Sperryn and Wood.

17181. Contact devices for apparatus for electrically lighting and extinguishing gas. Testor.

17364. Means for preventing the breaking of an electric circuit containing arc gaps or the like. Bousfield and Ozonized Oxygen Company, Limited.

18141. Electric block systems for railways. Robinson. (Date applied for under International Convention, Aug. 22, 1903.)

NOTES.

Street-Lighting.—The engineer to the city of Westminster has recently had an opportunity of seeing the street-lighting of Berlin, of which he speaks very highly; but apart from a portion of the Freidrichstrasse, which is very effectively but expensively lighted by incandescent gas of high power on ornamental columns 30ft. high, 25 to 30 yards apart, on each side of the street, he is of opinion that the lighting of the city of Westminster holds a premier place. It is interesting to note that even in Berlin, with a highly centralised controlling authority, it has been found useful to employ not only high-power incandescent gas, but also small incandescent lamps of the Victoria-street type and high-power electric arc lamps.

New Publications.—"Magnetism and Electricity (First Stage)," by R. H. Jude. (London: W. B. Clive and Co. 2s.) The revised edition of this volume includes a number of new features.—"Higher Text-Book of Magnetism and Electricity," by R. W. Stewart. (London: W. B. Clive. 6s. 6d.) This work has also been extensively revised, and a quantity of new matter introduced.—*Proceedings* of the Royal Society of Edinburgh, vol. xxv. (Edinburgh: Robt. Grant and Son. London: Williams and Norgate. 4s.)—"The Electric Tramcar Handbook," by W. A. Agnew. (London: Alabaster, Gatehouse, and Co. 2s. 6d.) This handbook contains a lot of instructive information for the motorman, inspector, and depôt worker. It should enable motormen who drive cars merely automatically to take an intelligent interest in their work.

Motor Tests.—Mr. Arthur Williams, of the New York Edison Company, reported some interesting motor tests at the recent Edison convention. In 12 large buildings in New York the average daily use of each installed lamp in a recent year was 3·22 hours, ranging from 14 per cent. below the average to 58·7 per cent. above. Of five large New York clubs the annual use averaged 4·75 hours, the range being from 22 per cent. below to 16 per cent. above the average. For motors in smelting works the average use was ·48 hours for each horse-power of the rated capacity; instrument makers, three hours; machine shops, 2·1 hours; general machinery, 4 56 hours, etc. The average for 50 motors was 2·26 hours per day for each rated horse-power. Tests show that the cost of operating ceiling fans on the basis of 5d. per kilowatt-hour is ·79d. For driving sewing machines the cost is ·175d. for belt-driven machines and ·1d. for direct-connected machines.

North-East Coast Institution of Engineers and Shipbuilders.—The twenty-first session of this institution will be opened at Newcastle to-night, when the new president, Lord Armstrong, will deliver his inaugural address. The dates fixed for general meetings, all of which will be held at Newcastle, are as follows: Nov. 18, Dec. 16, Jan. 20, Feb. 17, March 17, April 14, and May 19. The Graduate Section have fixed the programme for their sixteenth session. We notice in the report of the Council of last session that the papers read included "Technical Education in Germany," by Mr. Max Wurl; "Notes on the Construction of Stability Cross-Curves from Balanced Paper Sections," by Mr. J. H. Heek; and "Technical Education, with Special Reference to the Admiralty System," by Mr. B. C. Laws. Some of the papers were noticed in this journal at the time. Several papers were read and places visited by the Graduate Section. The members of all grades now total 1,131.

The Army and Wireless Telegraphy.—The wireless telegraphy experiments which a detachment of the Telegraph Battalion of the Royal Engineers have been conducting in Carnarvonshire have just been concluded. The system used was that devised by Sir Oliver Lodge and Dr. Alexander Muirhead, and the object was to test the practicability of communicating by this system between fairly distant points in spite of intervening mountain masses broken by passes and containing metallic minerals. Stations were accordingly established at Llanrwst, in the Vale of Conway, and within the grounds of Sir William Preece at Penrhos, near Carnarvon. The stations were thus about 20 miles apart, and separated by the lofty and rugged Carnarvonshire range. That the waves passed from station to station was soon ascertained, and the chief problem to be solved was the proper adjustment of the instruments. It is stated that the results have been successful, and that a good deal of important information has been gained.

Mining in China.—The Pekin Syndicate are making excellent progress with the sinking of shafts in their mining concessions situated in the Chinese interior province of Hunan. There is an installation of Babcock and Wilcox boilers, and these, fed by the native semi-anthracite coal, yield splendid results. The Chinese are evincing much interest in electricity, which is employed to illuminate the mines both on the surface and underground. Ready adaptability in the use of foreign appliances characterises the natives, who are adepts in the management of steam-engines. This trait is of considerable advantage to the syndicate, as the villagers are extensively engaged, with the full approval of the authorities, in the work of shaft-sinking. A quantity of additional plant has been requisitioned for the collieries belonging to the syndicate, and it is estimated that the output will total 2,000 tons per day. The coal is of good combustible quality, and is an excellent semi-anthracite, so that it is likely to be in demand for naval purposes. It is expected that the syndicate will be in a position to commence producing coal by the end of the year.

The College of Applied Science.—The scheme for establishing a college on the Charlottenburg principle, in connection with which Lord Rosebery announced, nearly a year and a half ago, that certain public-spirited citizens were prepared to present £300,000, has not so far taken a definite form, and the delay gave rise to rumours that this munificent offer had been withdrawn. As the result of enquiries, however, the *Daily News* states that such reports are groundless, the delay being attributable to the difficulty in securing a suitable site. A Government Departmental Committee, including representatives from London University and the London County Council, has the matter in hand, and is considering whether a free site can be provided at South Kensington. The committee are also considering how far certain existing institutions, such as the Royal College of Science, with its splendid laboratory equipment, might be incorporated in the scheme, so as to form the nucleus of the proposed institution. This plan may meet with some objection on the score that the location should be more central, but it has to be remembered that if the Government presents the site contemplated it will be equal to a gift of something like £100,000.

Electrolysis of Alkali Chlorides.—Messrs. A. Tardy and P. A. Guye contribute further notes on this subject to the *Journal de la Chimie Physikale.* The present paper treats of the function of the diaphragm during electrolysis. The diaphragm is the seat of four principal phenomena: (1) physical diffusion of the alkali from the cathode to the anode liquid; (2) migration of hydroxyl ions; (3) electrical endosmosis by which the anode liquid traverses the diaphragm; (4) flow of liquid from cathode to anode consequent on alteration of level due to (3). These effects are separately considered; the last is com-

Digitized by Google

pletely eliminated when the cathode solution is continually replenished and kept at a constant level. Characteristic constants for the different effects may be calculated from knowledge of the porosity and permeability of the diaphragm, and results of measurements with different diaphragms are given. In order to obtain the maximum yield of alkali, it is necessary to keep the levels of anode and cathode liquids equal, and to employ a current density of sufficient magnitude to cause the endosmotic current to nullify that in the opposite sense due to diffusion. The latter may be done by altering the current for a given diaphragm, or by choosing the latter with a permeability suited to the current employed.

The Sheffield Compensation-Limit.—It will be remembered that Councillor A. Muir Wilson, a member of the Sheffield Corporation, refused to accept a ticket when travelling on the tramways, his object being to test the validity of a notice given by the Corporation limiting their liability for accidents to £25. The Sheffield magistrate convicted Mr. Wilson of a breach of the by-law, holding that the acceptance of a ticket is not a voluntary proceeding, but is obligatory under the by-law. A statement of the case has just been remitted to the King's Bench for their opinion on the points of law involved. If the higher tribunal hold that the by-law in regard to the acceptance of tickets is itself tenable, the conviction will presumably stand, but there will remain the question of whether the notice limiting liability is not *ultra vires*. At the time of issuing this notice the Corporation had instituted reductions of fares, and the question arises whether this constitutes such a contract as would relieve the tramway undertakers from the full responsibilities imposed by the Carriers' Act. The view entertained by the majority of the municipalities, as expressed by them when a conference was held upon the Newcastle inter-running question, is that it does not. Apparently, however, it will be necessary to wait for a ruling on this point until it is raised in a specific form by an injured passenger.

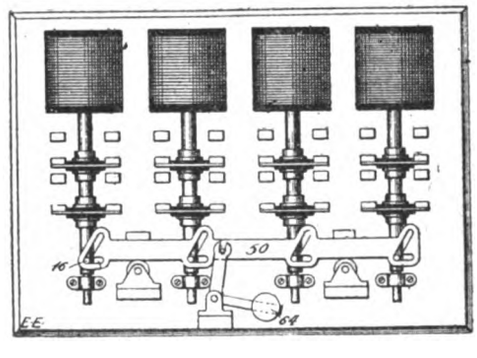
Tramcar Obstruction.—A section of the amateur magistracy at Leigh, Lancs., apparently considers itself more capable of interpreting the law than the Lord Chief Justice. Some time back one of the cars of the South Lancashire Tramway Company encountered a van at a point where the width of the road would not permit of the vehicles passing each other unless the van crossed over to the other side, where there was a greater margin. The driver of the van refused to do this, stating that if he crossed over he would be on the wrong side of the road, and would render himself liable to prosecution. Eventually, after waiting nearly an hour, the motorman backed to a loop. The Leigh magistrates adopted the view of the driver of the van, and refused to convict. This set up a somewhat extraordinary position, seeing that unless every tram, on finding itself confronted with such a difficulty as the above, resorted to the highly inconvenient expedient of backing to a loop the vehicles might remain facing each other until doomsday. Equity and common-sense surely dictate that under such circumstances a vehicle might safely commit the trifling irregularity, if such it be, of crossing to the other side of the road, and when, on the top of this, a Divisional Court presided over by the Lord Chief Justice holds that a vehicle has not an immutable right to remain on the customary side, one would think the Leigh justices would not have found much difficulty in returning a conviction. However on the case, reported in our last week's issue, again coming before them, a sapient moiety still considered that there was no case against the defendant, and as the chairman refused to give a casting vote the charge was dismissed. It is to be hoped that before long it will be authoritatively decided that the right side of the road is not invariably the left!

Steam and Electricity.—A correspondent contributes to the *Times* some highly interesting and encouraging figures upon the relative cost of steam and electric traction for railways. The returns issued by the Manhattan Elevated Railway, which a little over a year ago completed the electrification of its system, extending over some 40 miles, have foreshadowed favourable results, but hitherto comparisons between the two systems have been only approximate, as mixed traction has been in use. The *Times* correspondent now gives the result of the first year's working entirely by electricity, as compared with the last year when steam held sway—1901. The operating costs per car mile work out thus:

	Electricity.		Steam.
Maintenance of way and structures	·5325d.	...	·4635d.
Maintenance of equipment and power plant..	·6625d.	...	·652d.
Power supply and connecting transportation.	3·2505d.	...	4·673d.
General expenses	·2975d.	...	·35d.
Total	4·7340d.	...	5·9885d.

There appears to be a little discrepancy in the steam costs, which total rather over 6d. if the figures are correctly stated, but this only shows the results of the electrical working in a more favourable light. On the aggregates given, however, it will be seen that the operating costs show a reduction of about 1·25d. per car mile. During this period the operating percentage has declined from 44 73 in 1903 to 41·2 in 1904. In the same period the passengers carried on the same track mileage have advanced to 286,634,195—an increase of 40,047,173 in 12 months. The gross earnings went up to over £2,837,550, an increase of about £400,000, while the increase of net earnings totals some £318,820. These figures will be gratifying to the London underground railways, even if they do not stimulate the electrification of the suburban sections of trunk lines.

Interlocking Electromagnets.—A device has been patented in the United States for restraining the remaining magnets of a group from operation, accidental or otherwise, until the one that has been actuated is restored to its dormant condition. Some particulars of the invention, with the accompanying diagram, appear in the *American*



Electrician. A favourite means of accomplishing the object in view is to cause the magnet first operated to open the exciting circuits of the others. Mr. Wm. Baxter, jun., the present patentee, prefers to prevent the action of the remaining magnets mechanically, as indicated in the diagram. The arrangement consists of a locking bar, 50, capable of sliding horizontally, and held normally at the right-hand limit of its travel by a weight, 64, and bell-crank lever. The solenoid extensions each carry a pin, 16, which projects into an L-shaped slot in the locking bar. Should one of the solenoids be excited, the rising of its plunger will force the bar over to the left by the action of the pin in the slanting part of the slot, thus locking the other plungers,

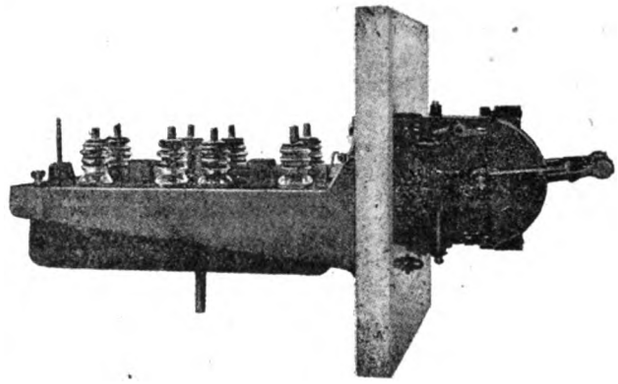
Digitized by Google

their pins being then in the horizontal part of the slots. The inventor does not allude to the circumstance that, in order to operate a locking mechanism of this kind, each solenoid must be very much longer than would be necessary merely to lift the circuit-closing contacts—probably three or four times as long.

Electricity in South Africa.—The *British and South African Export Gazette* announces that the difference of opinion on the part of Mr. R. Pape, borough electrical engineer at Port Elizabeth, and the consulting engineers, Messrs. Robert Hammond and Son, in regard to the character of the electric lighting supply for that town has been settled. Mr. Pape recommended direct current on the low-tension system, while Messrs. Hammond and Son, misled by the out-of-date map forwarded to them, urged a high-tension system, on the ground that the site of the generating station was not sufficiently central for the successful working of a low-tension system. The site is on the northern confines of the town, but it appears that rapid development is taking place still more northward, so that the site will become practically the centre of the district. On this being explained, Messrs. Hammond and Son quite agreed with Mr. Pape's proposal, and the borough and consulting engineers are engaged upon the preparation of specifications preliminary to calling for tenders. An expenditure on plant of £90,000 is at present authorised, and it is understood that the first orders will be for three sets of 400-kw. steam-turbine generators and the necessary cables, lamps, standards, switchboards, meters, fuse boxes, etc. Arc lamps will be used in the main streets and Nernst lamps in the lesser thoroughfares. In this connection our contemporary states that there is a wide and somewhat neglected field for electric lamp manufacturers in South Africa, and that Port Elizabeth offers a basis for building up a large business. As the local price of gas is 8s. 9d. per 1,000 cubic feet, it is expected that electricity will quickly step into favour for industrial and domestic purposes, thus creating a considerable demand for electrical fittings. From the same source we learn that the Kimberley Corporation and the De Beers Consolidated Mines Company have now agreed upon terms by which the latter will supply current for lighting the town. There are indications of activity among several other of the South African municipalities in the matter of undertaking electric lighting services.

Liege International Exhibition.—An influential committee has been formed under the auspices of the Associated Chambers of Commerce, the London Chamber, and the Anglo-Belgian Chamber of Commerce in London to organise a section representative of this country in connection with the international exhibition to be opened at Liège on April 22 next. As the exhibition, which will be under the direct patronage of H.M. the King of the Belgians, is to be held at such an important industrial centre the committee emphasise the desirability of Britain being worthily represented, and with this end in view they invite subscriptions to enable them to close arrangements with the exhibition authorities. It is estimated that the expenses will total about £5,000, towards which several substantial sums have already been promised, and as the time available is short it is essential that a decision should be arrived at without delay on the question of British participation. The site selected is a specially favourable one, a large area in the valley of the Meuse, including the beautiful Parc de Cointe, having been reserved. The general features of the exhibition will be those which usually characterise international undertakings of this character, and there will also be special attractions for visitors, and a Colonial section of great interest and importance. The contents of the various buildings will be classified in 21 groups, comprising all branches of industry, art, and sciences. A large portion of the exhibition is to be devoted to mechanical appliances, and it is intended to show machines in actual work. A feature of the exhibition to which much attention will be paid, and from which important results are expected, is a series of congresses and conferences, which will be held at intervals in the six months during which the exhibition will remain open. The Associated Chambers of Commerce of Great Britain will hold their autumnal meeting in Liège, and it is proposed that other of our prominent public bodies shall also hold meetings. The importance of this country making an adequate display is accentuated by the fact that our great rivals, including the United States, Germany, and France, have already reserved large spaces.

A New Oil Switch.—A new form of oil switch of the horizontal break type has been brought out by the Hanley Electric Manufacturing Company. A description of the apparatus, with the accompanying diagram, appears in the *American Electrician*. The breaking distance in the lower voltages corresponds to the standard practice, but in the



higher voltages it is increased by multiplying the number of breaks. Both the fixed and the moving contacts are disc-shaped with round edges, and are interchangeable. When the switch is opened, the arcing is stated to take place between portions of these rounded edges rather than over the flat portions which form the contact surfaces. From the bank of each disc a threaded projection extends, which in the case of the fixed contacts screws directly into the end of a hollow stud. In the moving contacts, however, two nuts secure each to a connection strip. This construction facilitates removal, and the expense of replacing the discs is trifling. Portions of the rounded edges after long use become damaged by the arc, and new portions can easily be brought into play by giving the discs a partial turn. This prolongs the life of the switch materially. The fixed contact discs are held against the lower ends of the insulators by hollow studs, into which they screw, and the lead wires are soldered into the top of these studs. By means of ball joints the moving contact discs are mounted upon the carriers, which are rigidly attached to the driving rod. The discs are said to be self-aligning in regard to the fixed discs, against which, when the switch is closed, they are pressed by strong coil springs. All parts requiring renewal can be removed and replaced with an ordinary wrench and screwdriver. The switches may be used in connection with the overload time limit or reverse-current relays. They are built for 2,500 and 6,600 volts in two, three, and four pole, single or double throw, with or without enclosed fuses and holders or overload attachment.

Cheltenham Electricity Undertaking. — An enquiry is proceeding at Cheltenham into the working of the electricity undertaking, as the result of the criticism of

Digitized by Google

a section of the ratepayers. The electrical engineer, Mr. Kilgour, requested an enquiry by an independent expert, and the Corporation, who some time since passed a resolution of confidence in the Electricity Committee and the engineer, requested the Institution of Civil Engineers to nominate the expert. Mr. James Swinburne was appointed, and the case for the aggrieved ratepayers was presented to him the other day by a representative of the ratepayers' association. The substance of the complaint is that the Electricity Committee have not acquired a thorough grasp of the business; that they have acted without the authority of the Corporation; that loans have been anticipated before the Local Government Board enquiry has been held; and that matters have been left too much in the hands of the chairman of the committee (Alderman Norman) and the electrical engineer (Mr. Kilgour). Specific charges against the management comprise the expenditure of sums of from £200 to £400 upon extensions of mains to private houses, the annual receipts for which fall short of the capital charge on the extensions; the absence of depreciation accounts, and, until the last two years, of trading and profit and loss accounts; excessive public lighting; inadequate rates for energy supplied to the light railway company and for private lighting; and the accumulation of annual deficits. The sums expended upon extensions of mains were in several cases less than the amounts sanctioned, and Mr. Kilgour pointed out that the extensions have been available for other customers, while in regard to the accumulated deficiency of £17,000 it was stated that fresh legislation would be needed if this were to be paid off by the ratepayers. Mr. Swinburne observed that the locality of the extensions had to be taken into account before the Corporation could be convicted of bad judgment. For the ratepayers it was argued that in more than half the cases of extensions beyond the compulsory area losses had been incurred. It will be remembered that the Electric Committee recommended last spring that the rates for energy should be revised all round so as to yield a larger revenue. The gross profit for the last financial year, which showed a considerable increase over that of the preceding twelvemonth, represented about 5 per cent. on the capital outlay. The ratepayers' association state that their criticism is directed not against any individual, but against the policy, or, as they term it, the lack of policy of the committee. The matter, however, is still *sub judice*, as Mr. Swinburne has yet to hear the other side of the case.

Electricity on Railroads.—The address delivered by Mr. B. J. Arnold, president of the American Institute of Electrical Engineers, at the International Electrical Congress, dealt with the application of electricity to steam railroads. He noted that the first important use of electric power for heavy electric railroading is credited to the Chicago World's Fair, although the City and South London Underground and the Liverpool Elevated were started about the same time. Mr. Arnold believes that electricity will be generally used on all the main railroad terminals and ultimately on the main through lines for passenger and freight service, though he does not anticipate that it will always be adopted on the grounds of economy in operation, nor that it will come rapidly or through the voluntary acts of the owners of steam railroads, except in special instances. At first the terminals will be equipped for special reasons, due either to the voluntary act on the part of the terminal companies to effect economy in operation or to public pressure brought to bear upon the owners through an increased demand on the part of the public for better service, on the ground that the use of the steam locomotive is objectionable in our great cities. Roads which run through populous countries will either build new roads or acquire for their own protection those electric railroads already built and operating in competition with them and utilise them as feeders to their through-line steam trains. Thus the steam railroad companies will gradually become interested in electric railways and eventually become the real owners of them. With these roads operating as feeders to the main-line system and with the terminals thus equipped and the public educated to the advantages of riding in electrically equipped cars, the next step will logically be the electrical equipment of the trunk lines between the cities already having electrical terminals. Consequently, a favourably located trunk line having a sufficient density of population will feel warranted in equipping electrically, and when this is once done the other roads running between the same competing points must sooner or later follow in order to hold their passenger traffic. With the terminals and main lines equipped electrically and the desire on the part of the public for more prompt and efficient freight service resembling that which is given by the steam roads in England and on the Continent, due to the great density of population, there will be developed a great high-class freight service conducted in light, swiftly moving electric trains, which can be quickly divided and distributed over all surface tracks of smaller American cities or through underground systems similar to that which is now being built in Chicago. This class of freight service would soon prove so large a part of the freight traffic of a road that the operation of the through-freight traffic by steam locomotives, though at present cheaper, would in time, as the cost of coal increases, grow less, until those roads operating an electric passenger service would ultimately use electricity exclusively. Mr. Arnold considered that the principal problem before the electric railway engineer to-day is how to make the most effective use of the high-pressure transmission and high-tension working conductor and maintain safety of operation.

Resonance Instruments at St. Louis.—The resonance instruments exhibited at St. Louis by Messrs. Hartmann and Braun, of Frankfort, of which a description, with the accompanying diagrams, is given in the *Electrical World* of New York, include an electro-acoustic tonometer. In this apparatus 36 sounding steel tuned tongues are arranged scale-wise in a straight line, and exciting magnets can be passed before the tongues on both sides. In connection with an interrupter, which is constructed so that it can be driven by means of a spindle from the axle of a machine by holding it on directly by hand, the slip of motors can be demonstrated and measured with this apparatus. This method also gives a very convenient means for connecting alternators in parallel, and it has the great advantage that it gives all the necessary information for this operation on one single scale; it enables the attendant to read simultaneously the number of revolutions of the running machine and that of the machine to be added; furthermore, to know exactly the moment of synchronism and the moment of the machines being in phase. Fig. 1 illustrates the connections, and it will be seen that the apparatus possesses three frequency meters, F/1, F/2, F/3. The magnets of F/1 and F/2 have only one coil each, but that of F/3 has two coils of equal number of turns. The frequency meters F/1 and F/2 are of the same construction. They consist of six tongues (Z) each, of which three are above and three below the normal frequency. The frequency of F/3 has only three steel tongues, of which the middle one is tuned exactly for the frequency of the station, while the left blade is $\frac{1}{4}$ per cent. lower, the blade on the right side $\frac{1}{2}$ per cent. higher. The alternator already in service is connected to the terminals I. and II., to which the frequency meters F/1 and F/3 are connected per-

Digitized by Google

manently, so that F/1 indicates the momentary and F/3 the normal frequency. Should another alternator be connected to the switchboard in parallel to the first, the voltage of this machine is impressed upon the terminals I. and II., the switch U being thrown to the right. Then only F/2 is connected and indicates the number of revolutions of the alternator, so that the switchboard attendant is able to see if the prime mover has to run faster or slower. As soon as this question is settled, the switch, U, is thrown to the left, sending the current now into the second coil of F/3 and bringing this frequency meter in

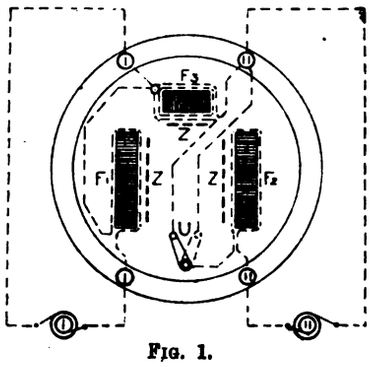


FIG. 1.

action. The magnetic field of F/3 is then composed of two magnetic fields of equal strength, but unequal frequency, bringing the tongues into vibration. If synchronism is approached very closely, these vibrations become slow and clearly pronounced so that they increase gradually from zero—*i.e.*, when the tongue is standing still—to a maximum amplitude of 30 mm., and this extension of the amplitude indicates the moment when the alternators are in synchronism and in phase. An apparatus of similar construction is used for counting the number of revolutions or the velocity of a belt, etc. The counter possesses 62 tuned tongues, and is either connected to an alternator

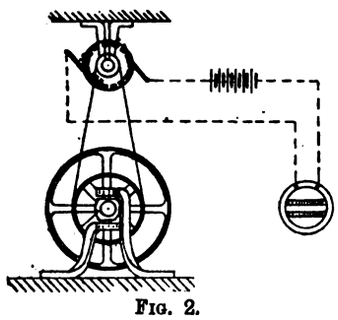

FIG. 2.

with a known number of poles or to a rotating direct-current interrupter as illustrated by Fig. 2.

A Gas-Turbine.—After the successes scored by different systems of steam-turbines in many fields of application which so far were reserved to steam power, the production of another type of engine could be anticipated. The question was to combine the advantages of steam-turbines—that is, their simplicity of design, small dimensions, and ready superintendence—with the principal advantages inherent in that other rival of steam-engines, the gas-motor—that is to say, with a smaller consumption of fuel. A gas-motor with a wheel-shaped recipient—viz., a gas-turbine—had to be designed. A similar prime mover would, like the steam-turbine, be free from any pistons, crank mechanism, and flywheels; being susceptible of construction in small dimensions even for large outputs, such a motor would be of a small first cost. Its superintendence would be rather simple, on account of the small number of running parts, and very cheap because of the smallness of the engine, while for the same reason the acquisition of the ground area occupied by the engine would be rendered easy. These principles were enunciated by Prof. Riedler at the last annual meeting of the Association of German Engineers. This expert is of opinion that the gas-turbine is the motor of the future and destined to surpass both the modern-day gas and steam engine. The idea of a gas-turbine is, by the way, a rather old one, Mr. Redtenbacher in his book on the caloric engine having as far back as 1853 drawn attention to the fact that a similar kind of engine would be an ideal hot-air motor, though the necessity of handling enormous speeds induced him to think that a constructive realisation of this idea would be impossible. Now, our methods of engine construction have been immensely improved upon since that date, while modern-day steam-turbine construction has shown means of reducing the speed to suitable limits by dividing the pressure gradient. A turbine designed by Dr. S. F. Stolze, of Charlottenburg-Berlin, patents for which were applied for as far back as 1873, but granted only in 1897 (this being due to some peculiar circumstances) is being brought out in Berlin by the Stolze Gasturbinen-Gesellschaft, and attracting much attention in engineering circles. In this "fire turbine," as the engine was originally called, the graduation of the pressure gradient with a view to diminishing the speed (which plays so important a part in steam-turbine construction) has already been made use of; in fact, the specification of more than 30 years ago describes fully the application of multiple-step turbines, while, on the other hand, a tightening device very similar to the labyrinth tightening designed subsequently by Parsons, is made use of. A large size engine of an effective output of 200 h.p. is in course of construction according to the above patent, and the following are the most striking features of this engine: On a common axle are mounted two sets of turbines of different design. One of these serves as air-compressor pump, while the other drives the shaft by means of heated air. Both of these consist of several rows of guiding vanes fitted to the engine casing, and of several rows of running vanes of a corresponding design, which are fitted to a common rotating cone, turning along with the shaft. Now, one of these turbine sets of turbine vanes will suck fresh air, compressing it to a given pressure through a preheater, which is heated with exhaust gases, and conveying the greater part into a chamber lined with fireproofing material. The smaller part is conveyed beneath the grate of a producer, where it gasifies a convenient fuel. The gas thus formed penetrates into the above-mentioned chamber, to be burnt there in suitable burners by the compressed air to carbonic acid and water vapour, while evolving large amounts of heat, these gases penetrating into the second turbine system, where they yield useful work by expansion in traversing the various steps. The process is thus mainly analogous to the cycle characteristic of all combustion engines, and which consist of a suction of air followed up by compression, mixing with fuel, combustion, expansion, and discharge. In most of the gas-motors now being built, the mixing, it is true, takes place before compression, and the combustion under increasing pressure. The working cycle of the gas-turbine resembles most the one of the Diesel motor. The efficiency of the turbine is doubtless susceptible of being increased beyond that of any existing type of prime movers. The Carnot cycle is, for instance, approached to more closely than with any other design of motor. Instead of producer gas, any other kind of gas can evidently be used, as well as carbonated air or benzine, alcohol or petrol vapours. The high practical importance of this system for automobile construction, which so far had at its disposal no other smoothly-running motors than electromotors in connection with accumulators, with their drawbacks, need hardly be pointed out.

THE GUANAJUATO HYDRO-ELECTRIC TRANSMISSION.*

The accompanying sketch map (Fig. 1) shows the location of a notable hydro-electric power development and high-potential long-distance transmission recently completed in the States of Michoacan and Guanajuato, Republic of Mexico. This plant is a very interesting one because of its many advanced engineering features, the remarkably short time within which it was constructed, and the fact that the work was completed within the estimates of cost. Under a concession from the Department of Encouragement, Colonisation, and Industry of the Republic of Mexico, the Guanajuato Power and Electric Company constructed a canal, pipe line, power generating station, transmission line, sub-station, and distributing systems for developing and marketing the energy of 8,000 litres (283 cubic feet) of water per second, diverted from the Duero River at the confluence of the Camecuaro and Chilchota Rivers, and returned above the Chaparacho Dam.

The following are some of the distinctive features. The head works, canal, and power-house are of massive and permanent construction. Special arrangements are made for regulating and measuring the water, and for collecting and disposing of the detritus carried by the water during the rainy season. The pressure pipe is large, conducting the water at a low velocity. It has no horizontal bends, and only a few vertical bends, all made with long radii. It is bedded in masonry at each end and is laid in a deep trench and completely covered. It terminates at the bottom in branches leading directly to the waterwheel nozzles. The nozzles are the largest yet used. The hydro-electric generating units have two 1,125-h.p. waterwheels mounted directly on the ends of the generator shaft and overhanging the two bearings. Energy is transmitted at 60 kilovolts a distance of 101 miles, over 19-strand hard-drawn copper cables, carried on specially designed porcelain insulators larger than any heretofore used. It is the first long-span steel-tower transmission line.

The inception and development of this enterprise are interesting. Some three or four years ago Mr. Leonard E. Curtis, who had been for a long time counsel in patent matters for the Westinghouse Electric and Manufacturing Company, and who had been obliged to leave New York and go to Colorado on account of his health, was sent to Guanajuato by clients to examine the title to certain mining properties there. In the course of this examination he became interested in the place, and was impressed with the very high cost of the power used for mining operations. Being familiar with modern developments in long-distance electrical transmission, it occurred to him that the conditions there were exceedingly favourable for the introduction of electric power if a suitable water power could be found within working distance. He employed a young American, whom he found there, to search for a water power, giving him a radius of 100 miles from Guanajuato to work in. The water power which has since been developed was found and an option obtained on it during the following year. In the meantime Mr. Henry Hine, under whose management the Stanley Electric Manufacturing Company had been built up, and who had resigned his position in that company when the ownership of it changed hands, had joined Mr. Curtis in Colorado, and the two had taken up the installation of power transmission plants together. After making a preliminary examination, they presented the matter to prominent capitalists at New York and Boston, who quickly subscribed the necessary capital, subject to an engineering examination. This examination was made by Mr. Robert McF. Doble, of San Francisco, Mr. H. H. Filley, of Kansas City, and Mr. Charles T. Main, of Boston. Their report was favourable, and the company was organised and proceeded with the construction work. Mr. Filley was employed as chief engineer of the company, Mr. Doble as consulting engineer, and Mr. Norman Rowe, formerly with the Westinghouse Company, was put in charge of the construction work at Guanajuato, and now has charge of the plant as general superintendent.

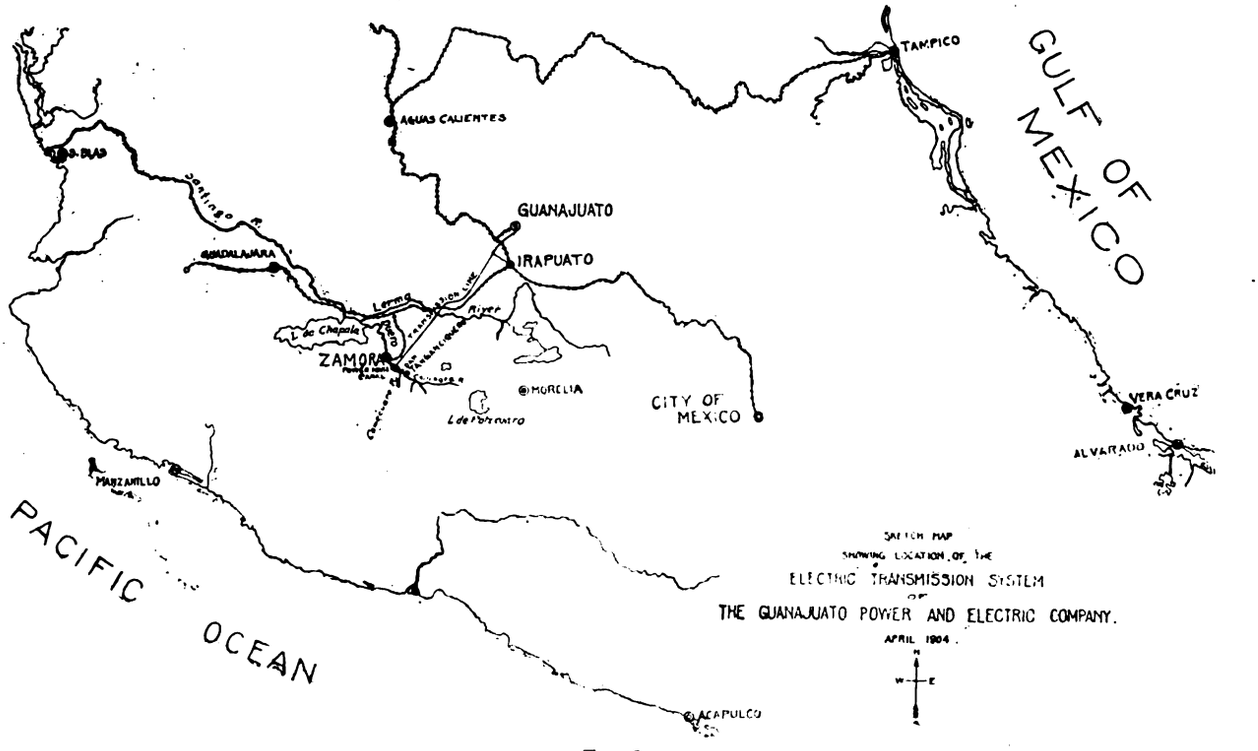

FIG. 1.

The watershed which supplies the Duero River has never been thoroughly explored. Its area is estimated at 400 square miles; it extends to the Continental Divide, and includes high timbered mountains and land-locked lakes. This portion of the State of Michoacan is a series of fertile valleys, lying one above the other, very like a series of vast terraces. The elevation is from 5,000 to more than 12,000ft. above sea-level. About 10 miles to the south of the Zamora Valley, and about 400ft. higher in elevation, lies the broad, beautiful, and fertile valley of Tangancicuaro, beyond which, to the south, at a greater elevation lies the valley of Los Once Pueblos (The Eleven Villages). The Tangancicuaro Valley is nearly surrounded by mountains, which toward the south are timbered and reach an altitude of from

* Abstract of a paper read by Robert McF. Doble before the eighth annual convention of the Pacific Coast Electric Transmission Association, Monterey, Cal. Reprinted in the *Journal of Electricity, Power, and Gas*, San Francisco,

Digitized by Google

10,000ft. to 12,000ft. Lake Patzcuaro, a large and deep lake with no known outlet, is located high up in this mountain range. The entire area is of volcanic origin. The rain-waters falling upon the high mountain lands penetrate the crevices in the basalt, slowly percolate to lower impervious strata, and then issue from the springs which abound in the valleys mentioned. The catchment area is so extensive, and the distance which the water probably traverses so great, that the subterranean reservoirs yield an exceedingly uniform volume through the numerous springs, which, during the dry season, furnish the entire volume of the Duero River. Such geological formation and source of supply for a river of considerable and of

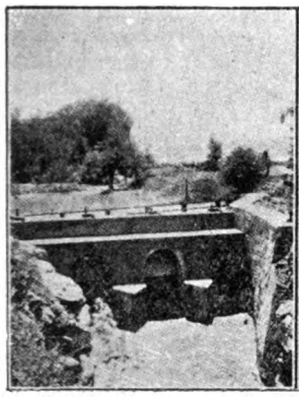

FIG 2.—The Head Works from the down-stream side.

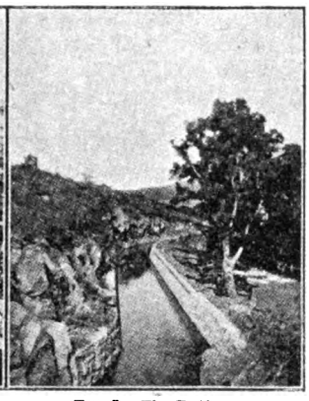

FIG. 3.—The Rating Flume.

uniform discharge is not without a parallel, though somewhat uncommon. Similar cases may be found in the lava districts of Northern California. The Duero River is formed by the confluence of the Camecuaro and Chilchota Rivers, which unite at the northerly edge of the Tangancicuaro Valley just above where a low ridge of basalt crosses between the neighbouring mountains. Through a break in this formation the river commences its rapid descent into the Zamora Valley, about 400ft. below. The Chilchota branch, with its many tributaries, extends in several directions throughout the Tangancicuaro Valley and to the similar valleys terraced above it, notably Los Once Pueblos, where are located the Chilchota Springs. It has a very extensive watershed, reaching to the high timbered mountains, and from it extensive irrigation is practised.

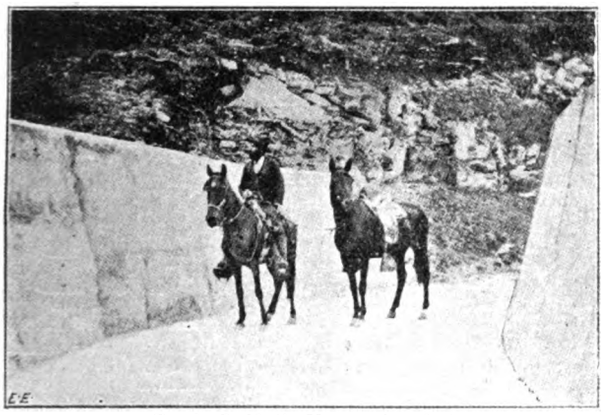

FIG. 4.—Inside the Masonry Aqueduct.

Hence during the rainy season it becomes a rushing torrent, and during the dry season the demands made upon it greatly diminish its volume. Its banks are closely lined with the sabino, or ahuehuete, trees, and from an eminence its course can be plainly traced through broad wheatfields.

The Camecuaro branch is only about a mile in length, with practically no catchment area. It is supplied by a large group of springs, the water issuing from the lava formation on the northerly side of a low hill. These picturesque springs are surrounded by a fine grove of very large sabino trees, which also closely line the banks, and confine the stream within its meandering channel until it unites with the Chilchota. The Camecuaro branch has very little fall from its source to the Chilchota, and it is plainly evident that its volume is remarkably uniform throughout the year. No water is taken from it for irrigation, but at times it receives a small addition to its volume as a result of the excessive irrigation of the wheatfields lying above it with water brought through a ditch from another spring. A number of careful current meter measurements were made, and compared with figures collected from every possible source, to determine the minimum discharge of the Duero River. These data led to the conclusion that there would never be less than a sufficient quantity of water available to warrant the construction of a generating plant of 8,000 e.h.p. capacity. The possibility of increasing the low-water flow by means of storage reservoirs located in the high mountains has not yet been fully investigated. Between the point where the water is taken from the Duero River—namely, at the confluence of the Camecuaro and Chilchota branches—to the point where it is returned to the river—namely, at the Chaparacho Dam—there are three dams in the river for the purpose of diverting portions of its waters into irrigation canals for the ranches of La Rojena, La Planta, and Tamandaro.

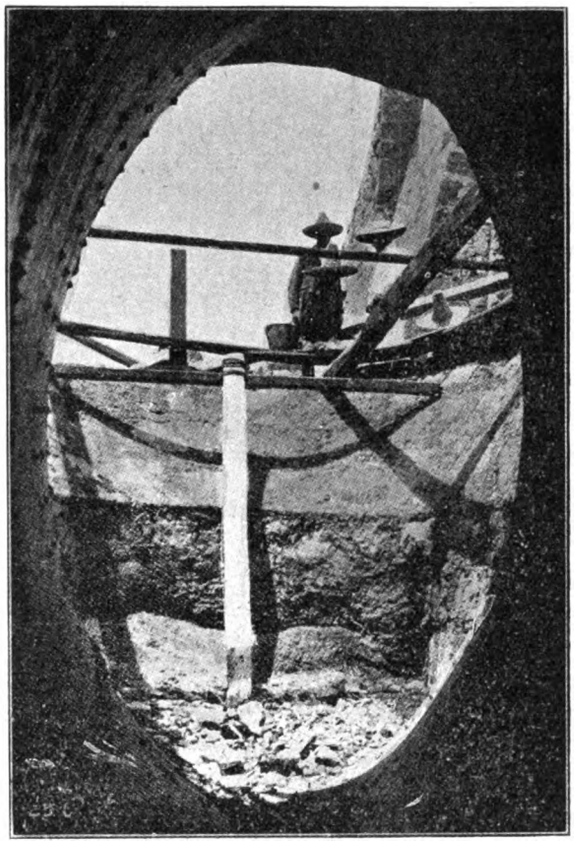

FIG. 5.—Looking out through the mouth of the great Oval Taper Section during the construction of the Penstock.

The masonry diverting dam is built of volcanic rock, the interior being laid up with lime mortar, and the exterior with Portland cement. It is a curved structure, with a radius of 88 19m., the length of the crest being 80m. Its elevation is 1,662·40m. above sea-level. It is computed as a gravity dam for a maximum depth of 1·60m. of water over the crest. A heavy steel fender, securely braced against the masonry, protects the entrance to the canal from the drift brought down by the freshets during the rainy season. Water is admitted to the canal through four head gates (see Fig. 2), each with an opening 1·25 by 2·00m at a maximum velocity of about 0 80m. per second. These head gates run in an angle-iron frame set in the concrete. They are made of wood heavily ironed, and are operated through a worm gear which runs on the threaded gate stem like a nut This worm gear nut is held stationary between ball bearings. The worm which turns it is provided with bronze thrust collars, and is mounted on a spindle having a removable hand crank at one end. The canal is 6,650m. long, is of trapezoidal section, 4m. wide on the bottom and 2·10m. deep. The side slopes are 1 : 1 in soft earth, 0·5 : 1 in hard rock, and 0 2 ; 1 where

Digitized by Google

the canal is lined with cement. Its slope is unifom 1 : 2,500. Its carrying capacity is 283 cubic feet per second at a velocity of between 2ft. and 3ft. per second. To provide for accurately measuring the volume of water allowed under the concession, a "rating flume" was constructed near the head works. It is about 100ft. of straight canal, lined with Portland cement held in place by sheets of expanded metal. The top of the wall on the side towards the river is finished with an adjustable metal weir (Fig. 3), which is set so as to act as a spillway when more than the proper volume of water is flowing. A short distance down stream the canal is widened and deepened, causing a reduction in the velocity of the flowing water to about one-third of the normal, so that any sand may settle to the bottom. This settling basin is provided with six valves opening from its bottom into a culvert which leads out from under the canal to the river. These valves are of new and interesting design, consisting of a circular cast-iron opening 18in. in diameter, closed by means of a conical cast-iron bell, drawn point up into the opening from below, and held there by means of a threaded stem and nut, which rests upon two channel beams spanning the canal. By turning the nut the cast-iron bell may be lowered to open the valve and wash out the sand which has collected at the bottom. Immediately below the settling basin there is an adjustable submerged weir. By means of the head gates and by the adjustable lip at the rating flume, in conjunction with the submerged weir, the quantity of water flowing in the canal may be closely regulated. From this point the canal meanders along the southerly side of the canyon; under a substantial masonry arch road bridge, 33ft. wide and 16ft. span; over a massive masonry aqueduct (Fig. 4) to a spillway, and thence to a second sand-trap, near the forebay. The spillway and second sand-trap are located so as to make use of the Barranca de la Rojena as a waste waterway leading to the Duero River.

A small storage reservoir is constructed alongside the canal at the forebay, by means of which a sufficient reserve of water is maintained to admit of cleaning the canal when required, and also to carry a very considerable peak load in excess of the normal capacity of the canal. A simple arrangement is provided for allowing the surplus water to flow into the reservoir from the canal during the hours of light load, and during that time to maintain the maximum head or pressure on the pipe line, regardless of the elevation of the water in the reservoir. Four suitable automatic gates, like flap-valves, are placed in the reservoir, near its bottom, opening outwards into the forebay. So long as the supply of water in the canal is equal to or in excess of the discharge through the waterwheel nozzles in the power-house, the maximum water-level is maintained in the forebay; if there is a surplus of water, it overflows from the forebay into the reservoir over a suitable weir. Whenever the requirements of the waterwheels are in excess of the quantity of water flowing in the canal, the water-level in the forebay is lowered, relieving the pressure on the outside of the automatic gates, which then open and let the reservoir discharge to make up the deficiency. At the entrance to the forebay the water passes over a measuring weir. On passing from the forebay to the penstock the water flows through a screen which removes all floating *débris*. The massive masonry penstock is strengthened by iron hoops embedded in its walls, and is interesting because of its excellent hydraulic lines. The water, after passing through the screens and through four gates similar to those at the head works, enters two ellipsoidal masonry basins, which gradually diminish in diameter toward the bottom, merging into the great oval taper sections, which are the heads of the pipe lines (Fig. 5). The design causes a gradual acceleration in the velocity of the water, and also prevents the formation of the whirling vortex which would draw air into the pressure pipes. The pipe line is 3,300ft. long, with no lateral bends. It varies in diameter

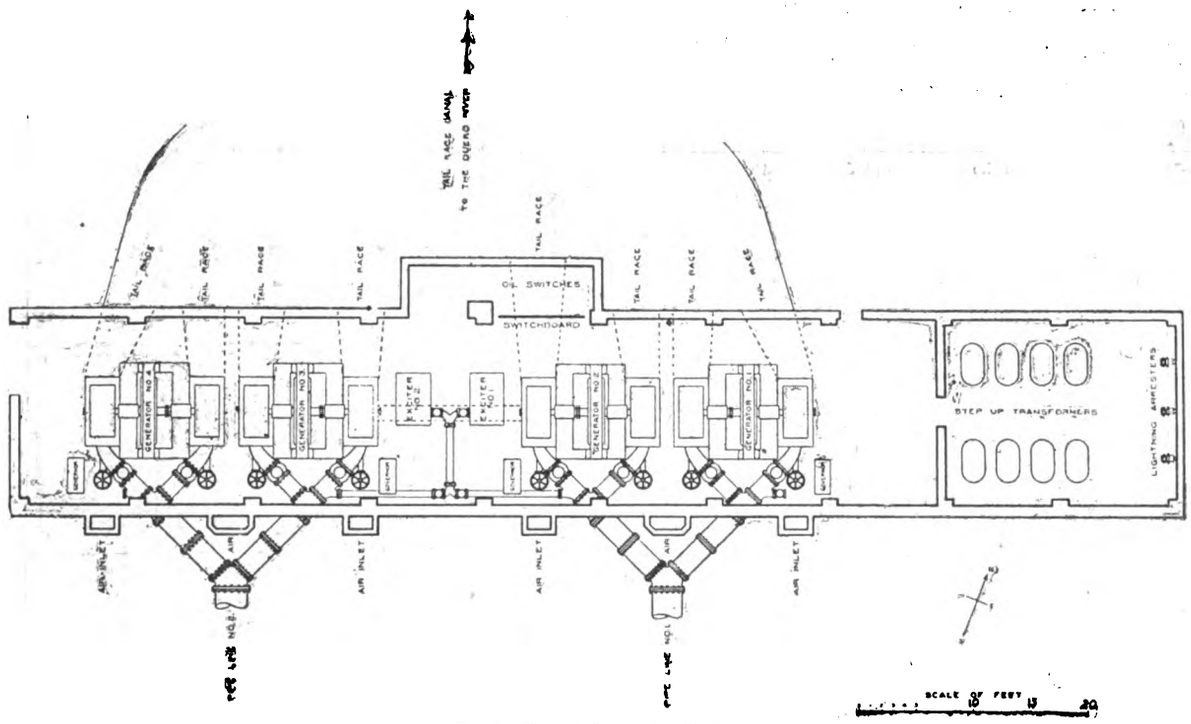

FIG. 6.—Plan of Generating Station.

and thickness, as shown in the following table, and was designed with a safety factor of 5.

Inside diameter of pipe.	Thickness of plate.	Approximate length.
69in.	$\frac{5}{16}$in.	1,100ft.
63in.	$\frac{3}{8}$in.	1,000ft.
63in.	$\frac{7}{16}$in.	100ft.
57in.	$\frac{7}{16}$in.	350ft.
57in.	$\frac{1}{2}$in.	350ft.
57in.	$\frac{9}{16}$in.	200ft.
57in.	$\frac{5}{8}$in.	200ft.
Total		3,300ft.

The decrease in the diameter of the pipe sections causes an acceleration in the flow of the water as it descends. This also made possible the nesting of sections for shipment. The pipe was made up from steel plates, in sections 27½ft. long, and weighing from 7,000lb. to 10,000lb. each. The steel plates were carefully selected and tested, the metal being required to have the following characteristics: tensile strength, 52,000lb. to 62,000lb. per square inch; elastic limit, not less than one-half the tensile strength; elongation, 25 per cent.; 180deg. cold quench bend flat on itself without fracture on the outside of the bent portion.

There are 480 separate plates in the pipe, each rolled tapering, the small end of one fitting inside the large end of the one next below it. All seams were lapped, and the longitudinal seams were designed so as to have at least

Digitized by Google

70 per cent. of the strength of the plate. These longitudinal seams were placed so that they are on top of the pipe and alternately opposite, with the caulking edges up. The longitudinal seams are double riveted, the circular seams single riveted. All the shop riveting was done by a large hydraulic riveter. The field riveting was done by hand by a gang of expert boilermakers sent to Mexico for that purpose. Two

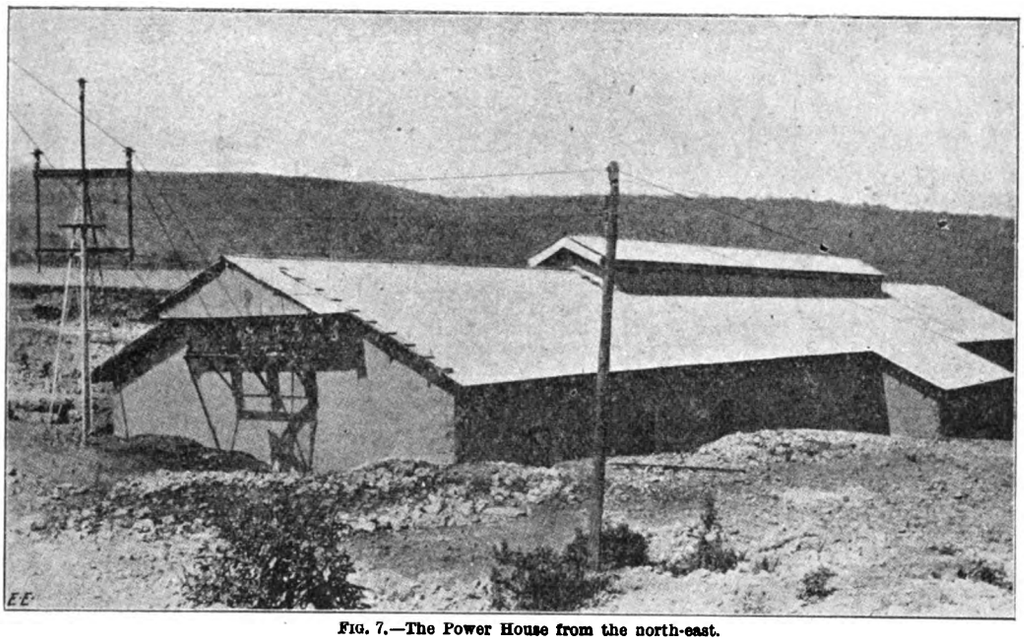

FIG. 7.—The Power House from the north-east.

riveters, a helper, and a man at the forge to heat the rivets could finish one circular seam a day. When riveted the pipe was caulked and an extra coat of preservative paint was applied. Each section of the pipe had on top near its lower end a hole, through which the hot rivets were passed from the forge to the man inside. The hole was tapped and a plug screwed in after the joint was riveted. Each section was plainly marked at the factory with letters indicating its position in the pipe line. The common practice of laying pipes of this character on top of the ground and supporting them on piers was not followed. A deep trench was dug, the bottom of which was graded on long tangents and with slight vertical angles. The pipe was laid in this trench beginning with the section nearest the power-house, and riveting on section after section, working up hill. Bell-holes were dug in the bottom of the trench so that the riveters might have room to swing their hammers. The back filling of the trench was done with great care, the earth being dampened and thoroughly tamped under and around the pipe. During the early morning hours, while the pipe was cool and at its minimum length, the top covering was completed. On Aug. 24, 1903, the pipe was tested, and so well had the work been done that not a single leak was found, although there are over 70,000 rivets. The pressure pipe terminates at the bottom of the hill in branching cast-iron pipes leading through the south wall of the power-house to the nozzles, as shown on the plan (Fig. 6).

The power-house (Fig. 7) has masonry walls, built of native volcanic rock. The roof is of galvanised iron supported by steel roof trusses, and lined with an anti-condensation lining. As shown in the illustration (Fig. 7), it is built in an excavation extending to a considerable depth below the natural surface of the ground. This was done for economical reasons. The pipe line profile is quite flat at the lower end, where the pipe line is the thickest and most expensive, and it was concluded that it would be cheaper to excavate a longer length of tail race and to dig deeper for the power-house than to extend the pipe line, as each additional foot on the 57in. pipes $\frac{5}{8}$in. thick would cost a considerable amount. The inside dimensions of the power-house are: length, 200ft.; width, 32ft. The floor is of cement. A low wall separates a length of 40ft. at the easterly end of the building, where the transformers are placed, which portion is 2ft. lower than the main room, and is provided with drains into the tail race. There are two 10-ton hand-operated cranes, which run the entire length of the building over both generator and transformer rooms. The erection of these cranes was an unusually simple matter. They were rolled into place from the surface of the ground, and subsequently constituted the basis of a movable platform, upon which the roof trusses were carried to place. The cast-iron branch pipes convey the water to heavy 30in. gate valves equipped with by-passes. The nozzles are attached to the gate valves, as shown in the accompanying plan (Fig. 6). These pipes are made of close-grained grey cast iron, and have lip and recess bolted flange joints with lead gaskets and are entirely buried in concrete. As shown in the plan, the nozzles are

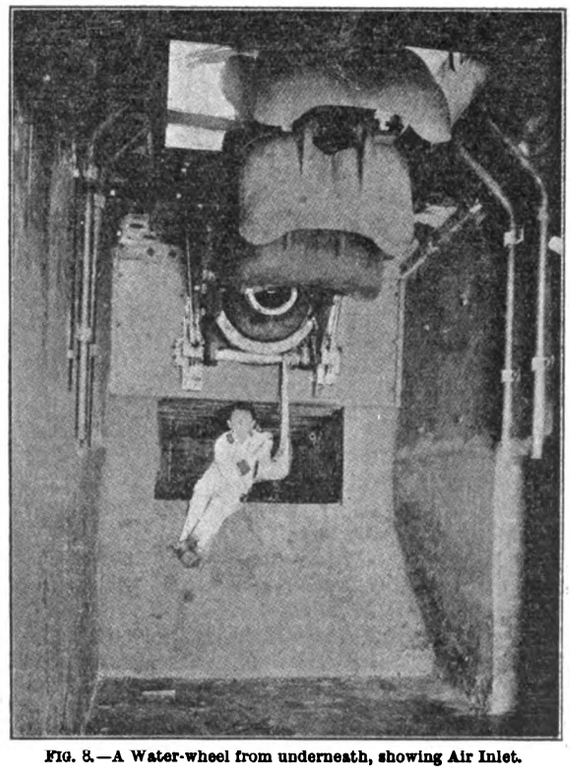

FIG. 8.—A Water-wheel from underneath, showing Air Inlet.

curved in form, making a 45deg. bend, so as to bring the axis of the jet at right angles to the waterwheel shaft. Each nozzle is provided with a removable tip, of cold blast charcoal iron, held in place by means of 14 $\frac{7}{8}$in. Tobin bronze studs with steel nuts. The nozzle is of the needle regulating type, having a core piece movable axially within it by means of which the annular area of the orifice is changed. The core piece is a Tobin bronze

Digitized by Google

stem with a phosphor-bronze bulb fitting into the nozzle tip. A continuation of the stem through a gland in the convex side of the nozzle casting is threaded, and by means of a bevel gear nut operated through a hand-wheel stand the needle is moved in and out to adjust the quantity of water discharged by the nozzle, so that the maximum economy in the use of water may be attained. This construction produces a solid jet of good form and of high efficiency over a wide range of discharge. Each nozzle is equipped with a deflecting hood, operated through a system of levers by a governor, for regulating the speed of the generating unit. The water, emerging from the nozzle tips in solid jets more than $\frac{1}{2}$ft. in diameter at a velocity exceeding $1\frac{1}{2}$ miles per minute, with a pressure of 138lb. per square inch, is projected into the buckets of the waterwheels (Fig. 8; also cross-section of generating station, Fig. 9). Each waterwheel has 15 huge buckets, more than 2ft. in width and weighing 254lb. apiece, made of close-grained cold-blast charcoal iron. The buckets are accurately fitted to the rim of the cast-iron wheel centre, and secured thereto by means of two fitted steel stud bolts. The entrance edges are sharpened, the hydraulic surfaces are ground smooth and painted, and each bucket is brought to a standard weight so as to obtain a dynamic balance. The cast-iron wheel centres are machine-finished all over, bored taper, key-seated, and secured to the projecting ends of the generator shafts by means of a feather and a large bronze nut.

The solid carbon steel shaft is 12in. in diameter from the waterwheels through the bearings, being enlarged to 16in. diameter in the middle portion. The bearings are 36in. in length by 12in. in diameter, of ring-oiling, water-cooled type of special design. The generators are revolving-field, engine-type, 2,300-volt, three-phase, 60-cycle, 200-revolution-per-minute machines, rated at 1,250 kw., but designed for a 25 per cent. continuous overload. Their characteristics as determined by factory test are as follows: full-load commercial efficiency, 95·77 per cent.; three-fourths load, 94·92 per cent. Regulation at full load and 100 per cent. power factor is 4 4 per cent.; temperature rise of armature, 21deg. C. after six hours' full-load operation. The total weight of the revolving element, consisting of the field, the shaft, and the two waterwheels, is about 50,000lb., carried on two bearings. The speed is regulated by means of a governor, operated by an oil-pressure system, actuating the deflecting hoods already described. The governors and the oil-pressure pumps are bolted from the generator shaft, as shown in Fig. 10.

The hydro-electric generating units above described are conspicuous by reason of their compactness and simplicity, there being only the stationary armature, the electric and hydraulic revolving elements mounted on the shaft, and two bearings. The 1,250 kw. unit occupies a floor space of only about 17ft. by 25ft. Continuous current for exciting the alternators is supplied by two 120-kw. 500-revolution-per-minute self-contained hydro-electric units, each of sufficient capacity to excite the four generators, so that one exciter is a spare. The exciter base is extended so as to receive the waterwheel housing. The waterwheel is mounted on the extended end of the shaft overhanging the bearing. Water is supplied to the wheel through a hand regulating needle nozzle, being conveyed from the main branch pipe as shown by the plan (Fig. 6). The current is conveyed from the generators to the switchboard,

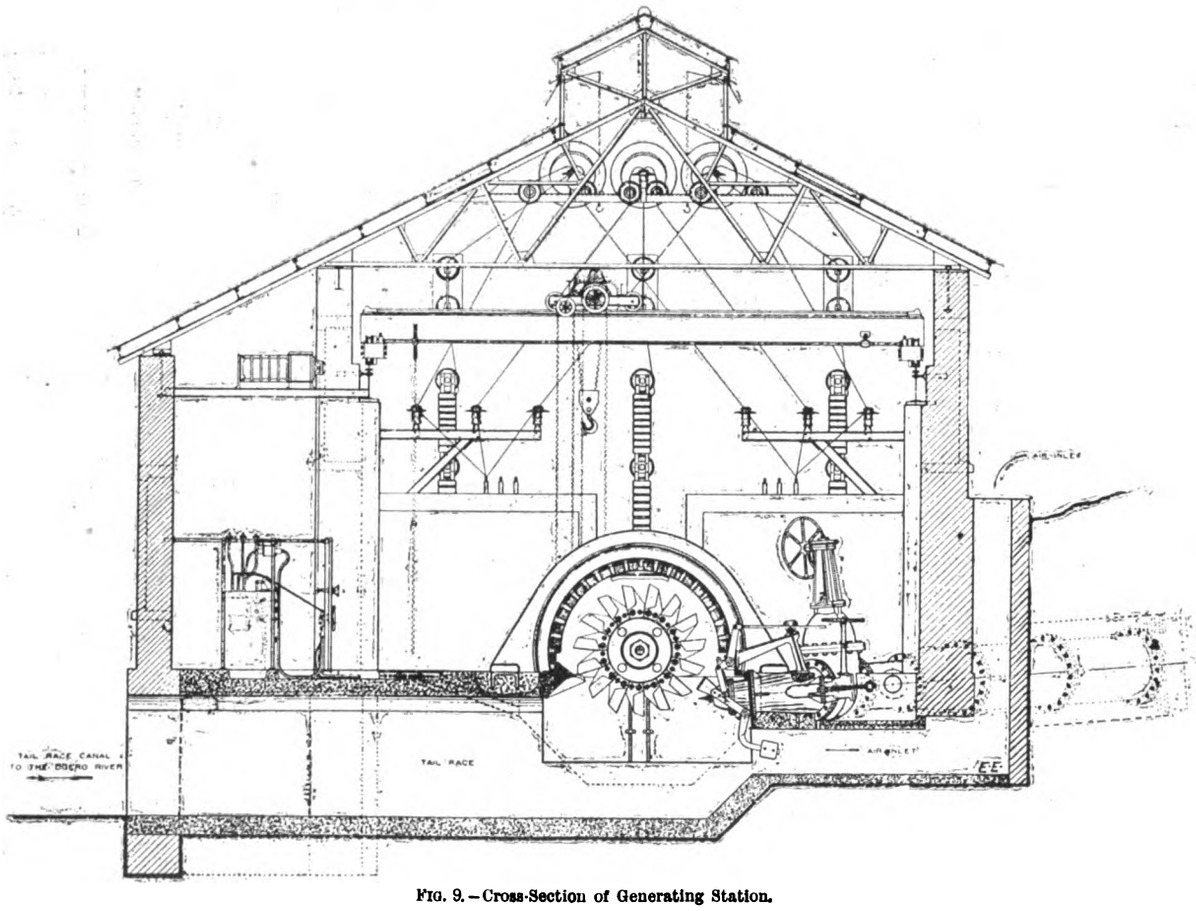

FIG. 9.—Cross-Section of Generating Station.

and thence to the step-up transformers, through lead-covered, rubber-insulated, copper cables laid in shallow covered ducts in the cement floor. The current passes from the generators through 600-ampere oil-break switches, each installed in a separate concrete compartment, to the 2,300-volt 'bus bars. The field rheostats are supported on 4in. I beams above the switchboard, and are operated by means of chains and sprocket wheels. The 'bus bars, oil switches, and wiring for the instruments are all back of the board and out of the way, being located in an alcove on the north side of the building, as shown in the plan (Fig. 6). The switchboard has seven marble panels, one for each of the generators, one for each exciter and one for two step-up transformer circuits. From the switchboard the 2,300-volt current is conducted to the 1,080-kw. static transformers, where the potential is raised to 60,000 volts for transmission. The transformers are delta connected on the low-potential side and Y connected on the high-potential side, having taps brought out through the top of the tank for line potentials of 40,000, 50,000, and 60,000 volts, the neutral being grounded. The efficiencies of the transformers as determined by factory tests are as follows: full

Digitized by Google

load, 98·295 per cent.; three-fourths load, 98·028 per cent. The transformers are of the oil-insulated water-cooled type; the tanks are 9½ft. in height, and occupy a floor space of 3ft. by 6ft.

From the step-up transformers the current is conducted to the transmission line, the wires passing out of the building through circular openings in the wall to a set of 60,000-volt disconnecting switches mounted just outside

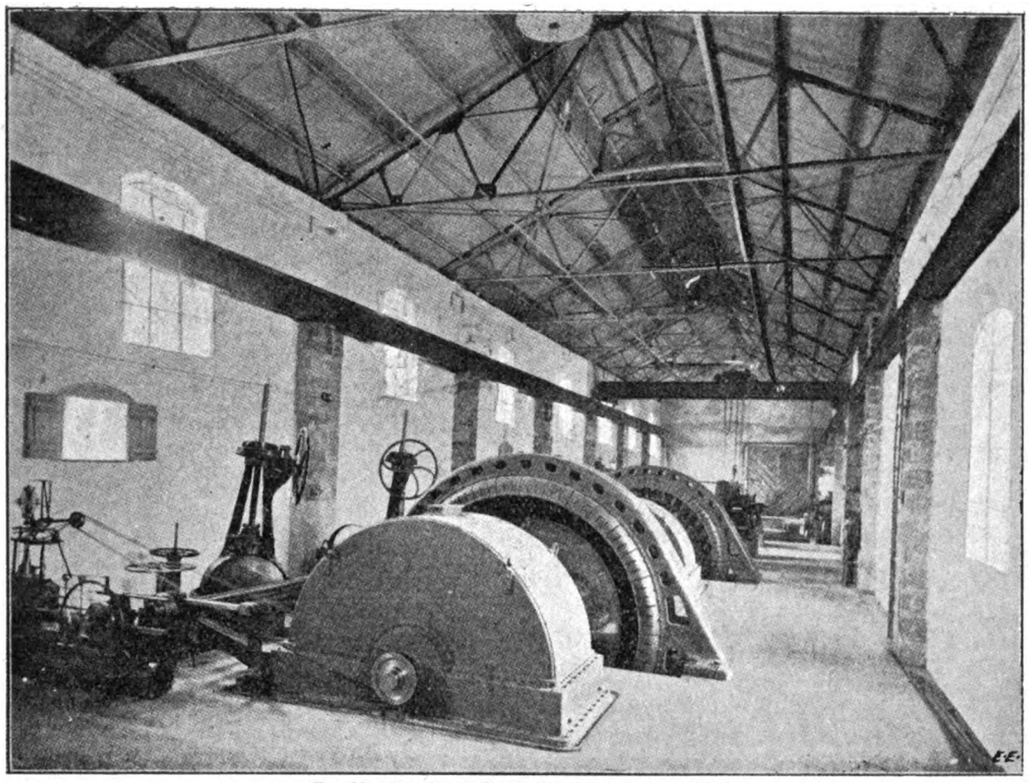

FIG. 10.—Interior of Power House, looking westerly.

of the building and thence to the first tower of the transmission line as shown in Fig. 7. On the inside wall of the building three rows of 60,000-volt lightning arresters are mounted, being connected through switches to the outgoing beds.

The 101-mile 60,000-volt transmission line differs materially in design from any line heretofore constructed, notably in the use of a hard-drawn copper cable instead of the usual solid conductor, metal pins, cross-arms and

FIG. 11.—Making a Joint in the Transmission Cable. Twisting.

towers for supporting the insulators, and unusually long spans. From the power generating station near Zamora the line passes for about 30 miles over rough mountainous lava formation cut by deep ravines. Near Guanajuato also there is some rough country, but for about 60 miles the line passes over clear rolling country, the most of which is under cultivation. The conductors are 19-strand hard-drawn copper cables, approximately ⅜in. in diameter, equivalent in carrying capacity to a No. 1 B. & S. G. wire, and weighing 1,340lb. per mile. This type of conductor was finally determined upon, after much study and many tests, because of its high conductivity, flexibility, and mechanical strength, the wires composing it having a tensile strength of over 55,000lb. per square inch. The cable was made and shipped in lengths of about two miles. The joints were made with special copper tube connectors, 12in. long and elliptical in cross-section. The two ends to be joined were passed through the connector in opposite directions, and three complete twists were given by means of special wrenches. Figs. 11 and 12 show the making of a joint. No soldering was done. The cables are placed in grooves on top of the insulators, 78in. apart, at the points of an equilateral

FIG. 12.—Making a Joint in the Transmission Cable. Splice completed.

triangle, and are tied in with No. 14 soft copper wire, it being considered that the small wire wrapped about several times would make an easy tie and not be apt to damage the small, hard-drawn strands of the cable. The cable was shipped on reels in lengths of about two miles. Where the topography and roads permitted six of the reels were delivered from the wagons each four miles. The cables then were pulled out over the cross-arms on rollers and spliced and tied in. In the mountainous sections the cable

Digitized by Google

had to be cut into shorter lengths. Diagrams showing the proper sag to be allowed at various temperatures and for spans up to 1,320ft. were prepared, based on a maximum strain of 20,000lb. per square inch, in the coldest weather and with the most severe wind. The calculations include an allowance for the mechanical elasticity of the cable.

The insulators are larger, heavier, and better than any heretofore used, and were required to stand a test potential of 120,000 volts for five minutes. They are over 12in. in height and 14in. in diameter, and weigh about 15lb. They are made of porcelain with a brown glaze and consist of four parts, as shown in the cross-section (Fig. 13). The top and the first petticoats were glazed together in the kiln, and the other two joints were made with neat Portland cement. The pins were likewise secured into the completed insulator. The pins are of cast iron, conical in shape, and cored hollow. The pin which carries the top insulator has an enlarged base, threaded on the inside, and is screwed on to the end of the 3½in. extra heavy pipe, which projects from the top of the tower. The pins which carry the lower insulators have rectangular bases, which are securely clamped between the ends of the 4in. channels which constitute the cross-arm, as

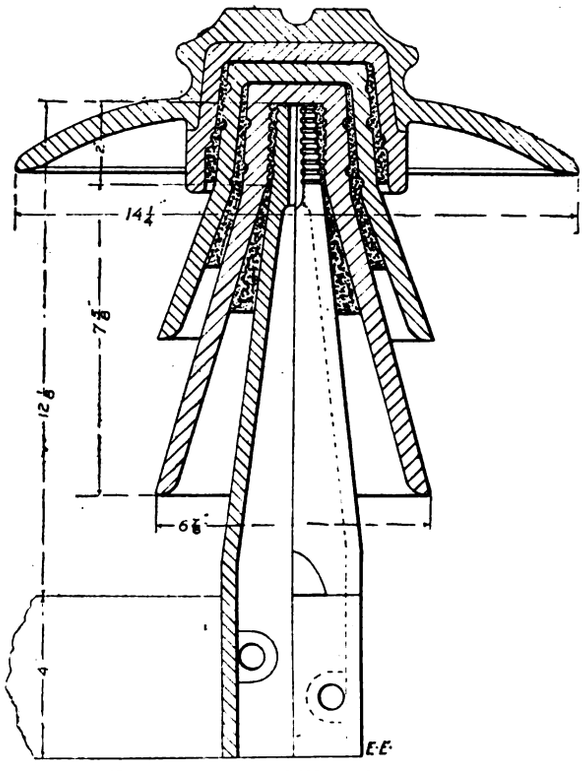

FIG. 13.—Cross-Section of 60,000-volt Insulator and Pin.

shown in the sketch of the top of the tower (Fig. 14). The insulators were shipped in two parts in barrels, and the cementing together of the parts and the cementing in of the pins had to be done in the field. After the parts were assembled the "field" was covered with the packing straw from the barrels in order to protect the insulators from the hot sun while the cement was hardening. The completed insulators, with the pins in place, were then carried out from the construction camps to the required location on the line two at a time by "man power." This was found to be the most satisfactory and economical method, as human labour is very cheap in Mexico.

The towers (Fig. 15) are special 40ft. four-post galvanised steel structures weighing about 1,500lb., made of 3in. by 3in. by $\frac{3}{16}$in. angles, braced and stayed with smaller angles and rods. Each post terminates in an anchor consisting of a piece of angle iron 30in. long secured at right angles. A 40ft. tower with the 3½in. extra heavy pipe fixed in position at the apex was built for testing. This tower was bolted in its assembled state to the 30in. wall of a five-storey brick building, so that its axis was horizontal instead of vertical as normally. A rope sling was attached to the pipe 70in. above the apex of the tower, and to this a wooden platform was attached. Weighed masses of pig iron were then placed upon this platform and the deflections of pipe and tower noted. When the load amounted to 900lb. the pipe began to show signs of yielding; the tower, however, was perfectly rigid. When the load was 1,234lb., the deflection of the pipe from a straight line amounted to about 6in. On removing the load a permanent deflection of about 1in. was found. The load was replaced and increased about 70lb. at a time. With each increase the pipe took an additional permanent set, and at a load of 1,560lb, it continued to bend until the load rested on the floor. The transportation and distribution of the towers was carefully planned and very satisfactorily carried out. The necessary quantities of parts were shipped to the several railway stations which had been selected as centres for the distribution along the line. From the railway stations the towers were hauled in wagons to convenient points on the highway and then were transported piecemeal through the fields on pack animals to the proper places on the transmission line; some of the longest pieces being carried by two burros in tandem. The assembling and erecting of a tower in place required skill and care. A gang of six Mexicans could assemble three towers a day. This was done with the tower lying

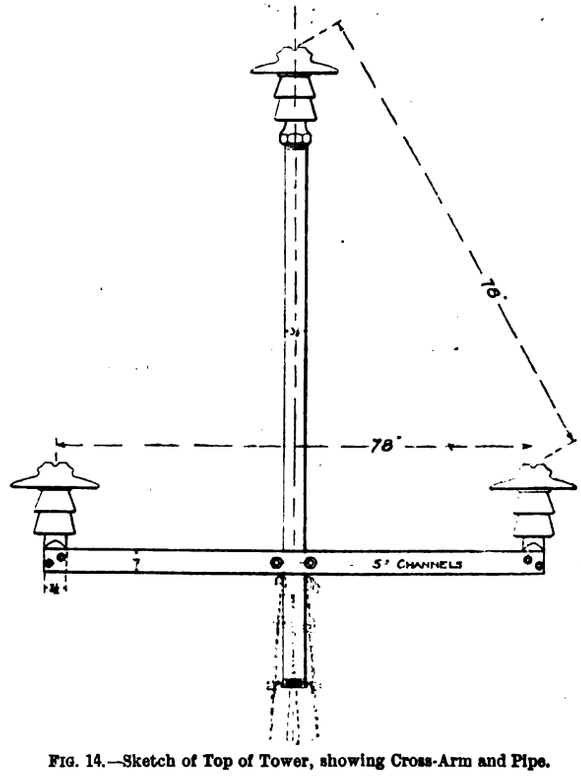

FIG. 14.—Sketch of Top of Tower, showing Cross-Arm and Pipe.

on the ground. A gang of 12 Mexicans under an American foreman could easily erect 12 towers a day. The all-metal construction of the supports for the transmission line was determined upon only after very thorough study and analysis and with a full realisation of the fact that the insulators must then be of the most reliable and simple construction. The quality and suitability of the insulators were, therefore, carefully looked after.

The advantages of long spans, with consequent reduction in number of supports and of insulators required, were so obvious that it was at once decided to adopt that type of construction. After careful study and many calculations and estimates the 40ft. towers spaced 12 to the mile were determined upon. The towers are spaced 440ft. apart, 12 per mile, except near Guanajuato, where the nature of the ground necessitated the use of a few 60ft. towers and spans up to 1,320ft. in length. Two No. 9 B B double galvanised iron wires for a telephone circuit are fastened on the transmission towers 10ft. below the copper power cables. They are tied to regular glass insulators placed on 12in. painted oak brackets bolted to tower legs. The telephone wires are transposed one complete revolution every four towers; the power cables are not transposed. High-resistance instruments are

Digitized by Google

used, and the telephone service is quite satisfactory. The climatic conditions for high-voltage transmission are usually good, and during the dry season, when the water is lowest, and when all the losses should be kept at a minimum, the atmospheric conditions are very favourable. Once or twice insulators at the top of the pole have been shattered, possibly by lightning. The long line of shining galvanised steel towers will catch the eye of the traveller as the train nears Palo Verde on the Guadalajara branch of the Mexican Central Railroad, or on approaching Irapuato on the main line from the north, at which points the transmission line crosses the railroad. It is almost straight, there being only a few slight horizontal angles.

The line is divided into four sections of about 25 miles, and is in charge of a superintendent whose headquarters are at the middle storehouse. At each of the three division points there is a first-class storehouse, a set of 60,000-volt disconnecting switches in the main line, a line foreman, and patrol man both mounted. In the middle of each section there is a second-class storehouse in the care of a mounted patrol man. At Guanajuato the transmission line cables enter the sub-station through a set of 60,000-

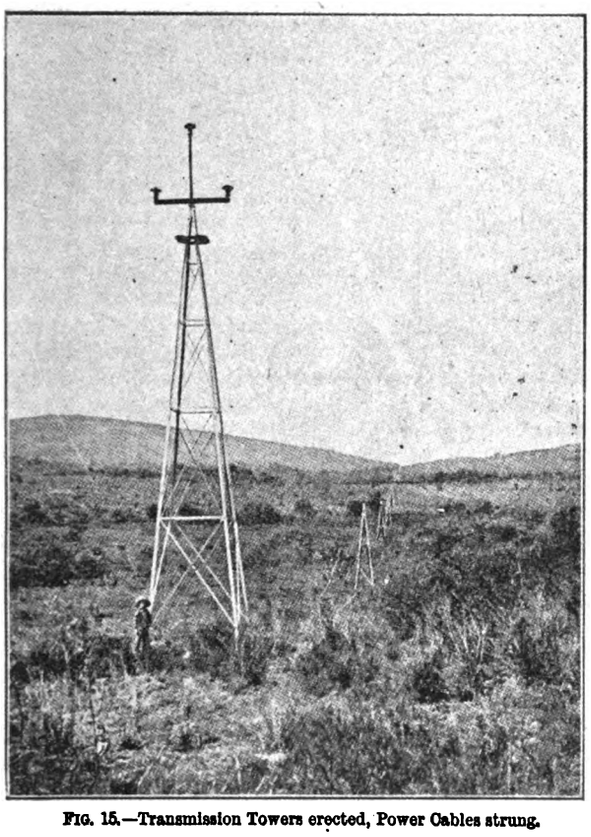

FIG. 15.—Transmission Towers erected, Power Cables strung.

volt disconnecting switches, the same as at the generating station. The Guanajuato sub-station is a handsome stone building with brick trimmings and a flat roof, standing in a beautiful grove of trees. The dimensions of the building are: length, 113ft.; width, 89ft. There is a central portion two storeys high, with well-proportioned one-storey wings on either side. One wing contains an office for the general manager, a drafting room, an accounting room, and a reception room. The other wing is fitted up for a repair shop and storeroom. The central portion contains the transformers. A 10-ton hand-operated crane runs over the shop and transformer room, passing through folding iron doors. The electric current enters the building, passes a set of lightning arresters with disconnecting switches, like those at the generating station, and goes to a bank of oil-insulated water-cooled transformers, where the line potential is reduced to 15,000 volts. These transformers are rated at 970 kw. each. Their efficiencies as determined by factory test are as follows: full load, 98·193 per cent.; three-fourths load, 97·93 per cent. From the step-down transformers the cables pass through ducts under the floor to the switchboard, thence to the six 15,000-volt three-phase distributing circuits, each of which is equipped with lightning arresters, and air-break switches with tube fuses. The solid copper wires of the distributing circuits are carried on 5½in. brown porcelain insulators, supported on wooden pins in wooden cross-arms on square yellow pine poles, 30ft. to 35ft. in height, 9in. by 9in. at the butt, and 7in. by 7in. at the top. The iron telephone wires are carried on the same poles, but are frequently transposed. The power wires are not transposed. At the mines and mills where the electric power is used, the potential is reduced in three-phase transformers from 15,000 volts to 460 volts for motor service. The Guanajuato city two-phase, 2,100-volt lighting system is supplied through a bank of 150-kw. three-phase to two-phase transformers, with a feeder regulator in each phase. A branch line leads from the main transmission line to Irapuato, the "Strawberry Station" on the Mexican Central Railway. The Irapuato sub-station is a brick building equipped with 60,000-volt disconnecting switches and lightning arresters, and the following oil-insulated, air-cooled transformers: four 200-kw. line potential to 15,000 volts; four 75-kw. 15,000 to 460 volts for motor service; two 40-kw. 15,000 to 2,200 volts for the city lighting system. Power is supplied to various small industries throughout the city, including three grist mills, a foundry, a wagon works, a paint factory, and various pumps used in irrigating the strawberry fields.

To the ingenuity of the American engineers, backed by American capital, is due this noteworthy development by which the energy of the swift and boisterous Duero River has at last been harnessed, and after conversion into electricity, has been transmitted over the 100 miles of intervening country to revivify the mining and other industries of the picturesque old city of Guanajuato, famous for its great mines, which are said to have produced during the past 350 years about one-fifth of all the silver in the world. Of late years these mines have not been worked to any great extent, largely because of the high cost of power. There were many interesting as well as difficult features connected with the construction work. The task of hauling to the construction camp was by no means easy, although the distance was not more than 10 miles. The way lay through the city of Zamora, thence to the little town of Jacona, and thence about six miles along the State highway to the construction camp at the little Indian village of El Platanal, where the power generating station is located. American mules were purchased, and specially-designed American wagons were provided, in order that adequate means should be at hand for carrying the heavy parts to their places. The roads through the country are mostly over black adobe soil of indefinite depth, and a few rainy days are sufficient to convert such roads into regular quagmires. The haul through Zamora and Zacona was by far the worst part, since the streets had been improved (?) by a pavement of stones of no small diameter, and in spite of the wide tyres the wagons would break through the pavement into the underlying mud during the short intervals of time allowed for the animals to rest. It is to the credit of the transportation organisation that all of the hauling was done without the loss of or damage to a single piece of apparatus. Carrying out a project of this magnitude in Mexico is made doubly difficult by the dense ignorance and absolute carelessness of the labouring class. The labourers, or peons, are mostly Indians or half breeds, except where they are specially imported. These people wear as little clothing as possible, eat and drink whatever comes to hand, smoke cigarettes incessantly, are always ready to talk or play, and are never ready to work. From time immemorable they have carried things on their backs, and it becomes necessary for the American to adapt himself to their ideas in order to get work done. It is exceedingly difficult, if not impossible, to teach them new methods of working. The customary method of handling dirt is by means of baskets or costals (a small piece of burlap) carried on the back. It is reported that when one contractor attempted to introduce the use of wheelbarrows the peons preferred to carry the barrow, load and all, on their backs rather than learn how to wheel it on a runway. The wages paid to the labouring man vary from 40 cents to 60 cents per day, Mexican, if he be unskilled, 75 cents to 1·25dol. if he be a cabo (gang boss), from 2·50dol.

Digitized by Google

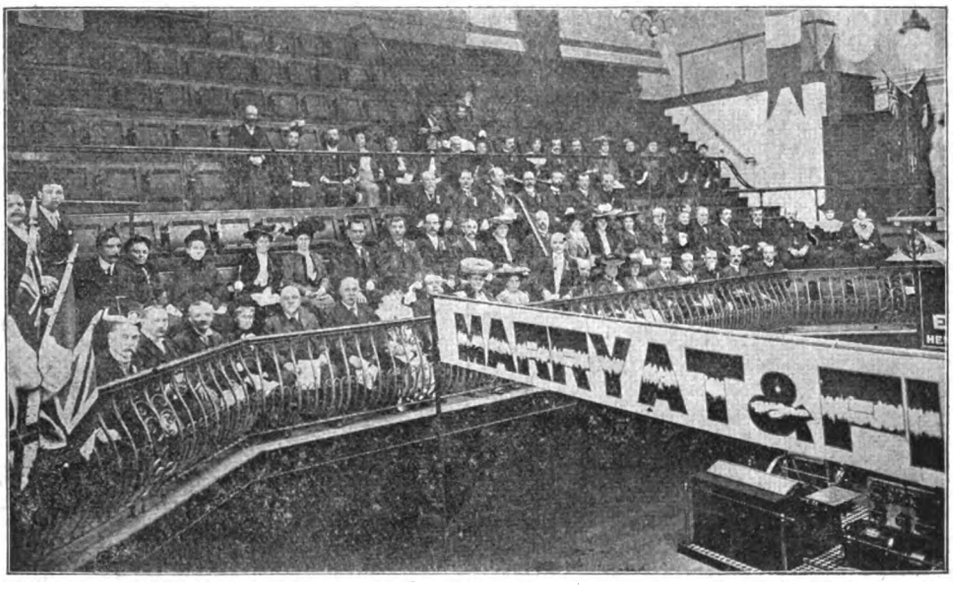
upwards if he be a skilled artisan, and are unquestionably greater than he knows what to do with. On Saturday night the man whose week's work has brought him 2·40dol. in Mexican silver is so wealthy that he makes a bee-line for some place where he can spend his money with the least exertion. Saturday night is usually spent in drinking the vile intoxicants, which are very cheap, and in gambling, and there is rarely a Sunday in a large construction camp that is not celebrated by some shooting or stabbing affray. Monday has been christened San Lunes (Saint Monday), because the men are entirely missing or medio crudo (half drunk), and trying to taper off. In addition to Sundays and Mondays, there are in each month a few church holidays upon which no good Mexican works. The men bring their wives and families into the camp and set up housekeeping in a one-roomed shack, easily constructed in half a day, of boulders, and thatched with weeds. Packing boxes were good enough for some, and one family squatted in a short spare length of steel pipe 69in. in diameter. Nature is kind to these people, furnishing warmth and food, such as it is. The only incentives to work are curiosity and a desire to obtain the means with which to get drink and to gamble.

The short time in which this project was executed is most remarkable, and is characteristic of the management. The preliminary examination was made in March and April, 1902, construction was begun in the fall of the same year, and in October, 1903, the plant was put into regular operation. This undoubtedly establishes a record in Mexico for rapid and efficient execution of construction work of a technical character and of considerable magnitude, especially in view of the fact that the work was completed within the estimates of cost.

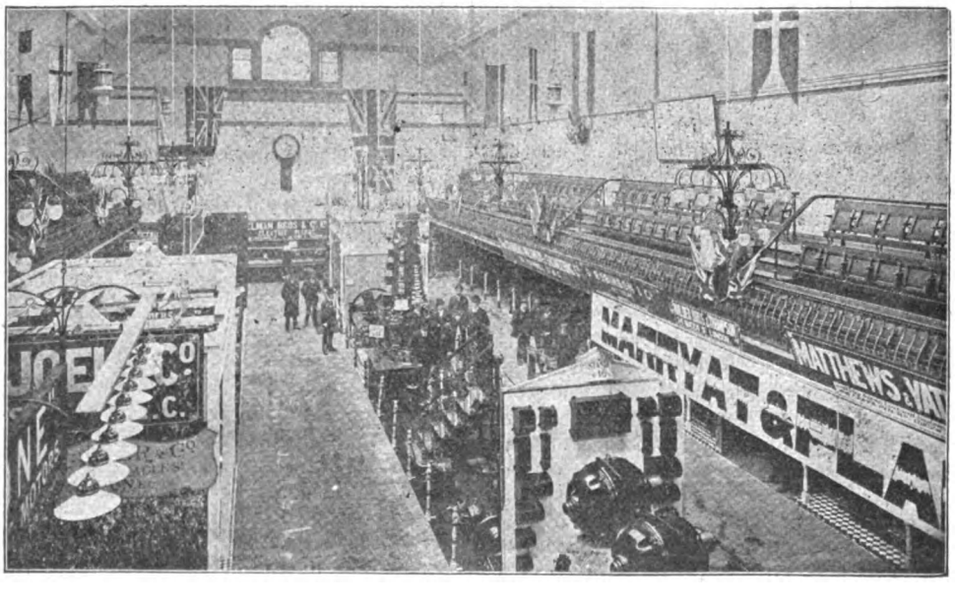
SHOREDITCH ELECTRICAL EXHIBITION.

If the number of visitors to this exhibition, the opening of which we chronicled last week, be any index to its success, then assuredly the efforts of the promoters will be well repaid. When our representative paid another visit to the exhibition on Wednesday he found it thronged, and the borough electrical engineer, Mr. C. Newton Russell, informed us that the sightseers up to that day totalled something over 14,000. More gratifying still, we understand that the exhibitors' order-books have been in frequent requisition, and that there have been numerous enquiries. Through the enterprise of one of the committee, a series of picture postcards with excellent views of the exhibition has been produced. These postcards, specimens of which we reproduce, are on sale at the exhibition, and are in great demand.

Our attention was specially directed to the planing machine exhibited by Messrs. J. Sagar and Co., of Halifax,



Shoreditch Electrical Exhibition.



Shoreditch Electrical Exhibition.

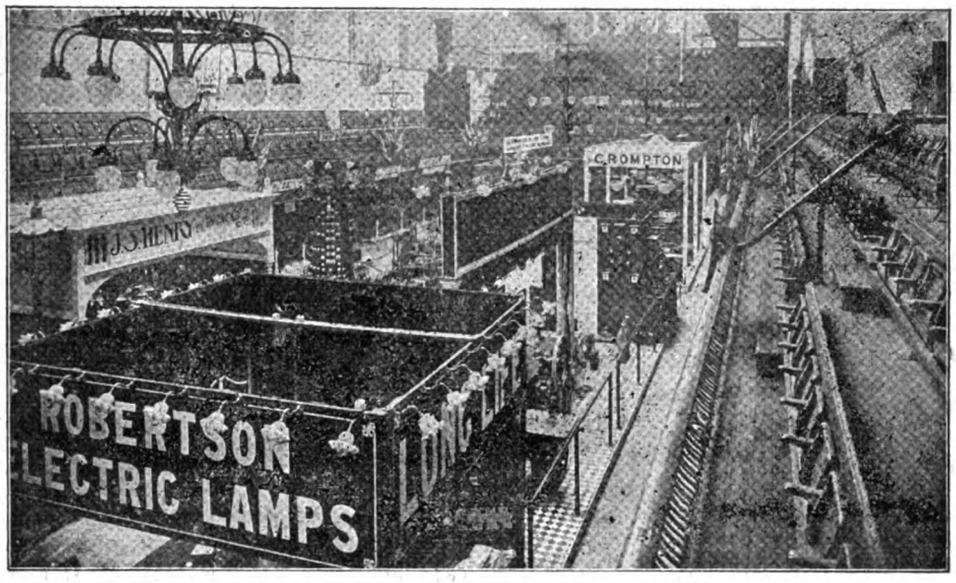
Digitized by Google

and Watling-street, E.C. This machine, with two others they are exhibiting, was driven by a 6½-h.p. motor, and it performs a variety of planing operations with the greatest facility. A good deal of interest attaches to this exhibit, as woodwork is one of the chief industries of the neighbourhood. Now that those engaged in the trade have had an opportunity of seeing the efficiency and economy of electric motors, from the smallest size upwards, it may reasonably be expected that there will be a substantial increase in the demand. The appliances of Messrs. Joseph Richmond and Co. for manufacturing articles of stationery attracted a good deal of attention. After the gum has been applied to the paper by the "Pellatt" machine, layers of the paper are operated upon by the "Reay" folding machine, with the result that, operating at a moderate speed, 2,500 envelopes are turned out per hour.

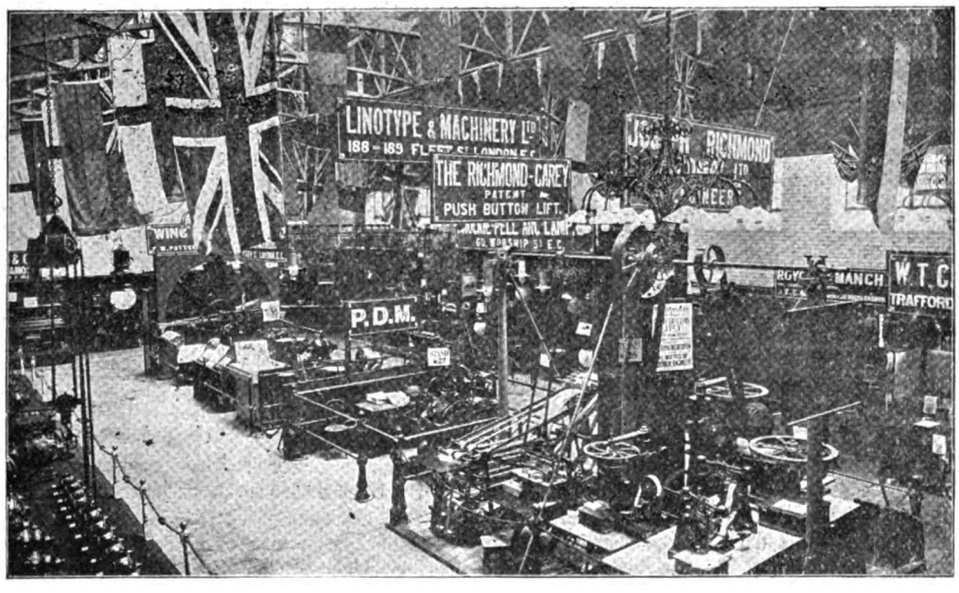
The Electromotor and Dynamo Company include in their extensive exhibit the Grisson "E.D.C." speed-reducing gear. This ingenious device occupies little space, runs silently, and has a mechanical efficiency of 95 to 96 per cent. We had a further opportunity of witnessing the admirable qualities of Messrs. Humpage, Jacques, and Pedersen's electric hoist. This apparatus is under complete control, being self-sustaining on the brake. The hoist is driven by a direct-current motor coupled direct to the high-speed side of one of the firm's special enclosed spur reducing gears.

An illustration of the firm's combined motor and reducing gear appeared in last week's issue. The reducing gear can be used with the motors of any maker. It is made in all standard ratios from 5 to 1 to 20 to 1. The gear is coupled to the armature spindle of the motor; it has a balance double drive; and the gearing, which runs in an oil bath, is covered in so as to protect it against dirt and dust. The results of tests given in Messrs. Humpage and Co.'s catalogue testify to its high efficiency.

Messrs. Marryat and Place had crowds watching their electric furnace, in which steel was being melted. The following night platinum was to be subjected to the furnace, which develops a temperature of 3,700deg. C. The General Electric Company's stall, on which demonstrations are given of the manufacture of the Robertson lamp, was likewise surrounded, this attraction being in great favour with the onlookers. The other prominent features were recorded in last week's issue.



Shoreditch Electrical Exhibition.



Shoreditch Electrical Exhibition.

The promoters are certainly to be congratulated upon the extensive patronage which is attending their efforts. Those who have not been to the exhibition should lose no time, as it closes to-morrow.

Portsmouth.—A proposal is on foot to carry the arc light system into all roads in the borough where there are tramway lines. The matter is under consideration by the Corporation.

NOTES ON MOTOR-STARTING SWITCHES.

[CONTRIBUTED.]

(Continued from page 551.)

In addition to the above requirements, which apply equally to every starting switch no matter for what purpose it is required, there are also special necessities in many starting switches which are called for owing to the special purpose for which the motors they control are used. The switches so far considered have been for direct-current, shunt-wound motors, leaving out of the question alternating-current motor switches. There are other types which must receive consideration. These include the starting switches for series-wound and compound-wound motors, and also the switches required for reversible motors. This latter type of switch is usually employed for lift work, and while in the majority of cases the lift is controlled only at the cage, there are many instances where it is necessary, or at any rate desirable, to control the motor from one or more points at a distance. When the points of control are manifold, it is essential that while each shall be independent of the others, yet it shall be impossible for the operator at one point to supply current for a downward direction of the cage at the same time that an operator at another point is supplying current for an upward journey. All this means special contrivances in the switch. In dealing with hoist switches, it may be remarked that for dinner lifts it is usual to arrange the controlling apparatus so that the lift will travel only to the intended floor. Various other starting switches are required for special purposes. At times it is necessary that the motor shall be started automatically when the water-level in a tank attains a certain height, and so on. Whatever the special purpose, or whatever the special type required of starting switch, the requirements already laid down hold good, and the switch should conform to these; the special arrangements must be considered as additionals, and not as equivalents for some of the specified requirements.

The conditions specified as necessary are not difficult of attainment, and if the customer will pay the price for a well-designed switch, he can be supplied with one that will be a sound electrical and mechanical engineering piece of work, and which will last for years without giving any trouble provided it receives anything like fair treatment. The unfortunate part is that, as a general rule, the customer is not prepared to pay the price of high-grade switch, but requires something cheaper and at the same time reliable. This being the case, some of the specified conditions must be deleted and others modified, and the question then becomes which of the conditions shall be abandoned.

The type of starting switch which is most commonly met with in practice is designed so as to be simple in construction, and usually has a movable lever operated by a coiled spring so arranged as to bring the lever back to the zero position if the retaining force is withdrawn; the switch is usually fitted with a no-load release. This is made in the shape of a small electromagnet energised by the shunt current, a small soft-iron armature being fitted to the lever of the switch, so that when this latter is pressed right home the soft iron closes the magnetic path across the poles of the no-volt bobbin. The lever is thus magnetically held in position; should the current be interrupted, the bobbin loses its magnetism and the lever flies back and so opens the switch. In addition, the switch may or may not be fitted with an overload preventer. The contact lever may either be operated by hand, in which case the speed at which the motor is started is left entirely to the discretion of the operator, or the lever may be moved by means of a screw and worm wheel. In this case, when either the no-volt release or the overload preventer comes into operation, a bar drops so as to prevent the current being switched on again until the lever has been screwed back to its off position. This type of switch appears to answer all the necessary conditions, provided it is well made and is of ample size to deal with the maximum current taken by the motor, and also provided that the shunt is so coupled up that a path for the induced current is afforded. The switch, however, is far from being a perfect piece of mechanism, and possesses several faults. In the first place, it is not advisable to leave the speed of starting in the hands of the operator, and the device of adding a wormwheel, while it cures part of the evil, is not altogether satisfactory. We have seen that the break from contact to contact should be as quick as possible, while the lever should rest on each contact sufficiently long to enable the motor to attain the speed corresponding to the current supplied at each contact. This condition is not attained, and instead of the time of starting being occupied only while the lever is on the contacts, it is equally distributed over the whole operation of break between contact and contact and of resting on the contacts, so that burning must inevitably occur.

Another point of great moment is that the price of the switch has to be cut to compete against other makes, and consequently due attention is not paid to the resistance coils. These are usually mounted behind the slate on which the switch proper is mounted, and then enclosed in a ventilated iron cover. Too often the coils simply consist of iron wire wound on a removable mandril, which is withdrawn after the coils are wound, and there is nothing to prevent sagging taking place. The iron should be, and often is, galvanised, but in time it rusts, and then the switch gives infinite trouble, the only cure being to rewind the coils entirely. At times an advance is made on this method, and the coils are wound on fibre or paper mandrils. This is only a temporary improvement, for the mandrils or cores prevent the free radiation of heat, and are soon affected by the atmospheric conditions, and commence to buckle. Then the effect of sagging is greatly aggravated, and the coils must be rewound.

The effect of starting the motor too rapidly is to cause a big rush of current through the armature. Now, while in theory we know that Ohm's law holds universally in every case, there are modifications which occur in practice and which can be usefully employed. If there are two paths open to the flow of a current of electricity, theory will state that the current will divide itself between the two paths inversely in proportion to the resistance of each. Practice shows that if the resistance of the two paths varies greatly, all the current will flow through the path of low resistance and none through the path of high resistance. This is shown in the case of a shunt-wound generator, which will refuse to excite on closed circuit if the resistance of the outer circuit is very low. It is also shown in the action of the overload preventer of many starting switches, which simply short-circuits the release coil, thus offering a path of such negligible resistance that no current will flow through the higher resistance of the bobbin. The same effect has been used in the design of one type of starting switch. The switch is fitted with two handles, so arranged that it is impossible to move the second switch, which actually controls the supply of current to the motor, until the second switch has been first moved to its far position. This auxiliary handle is held in its on position by means of a small subsidiary coil, similar to the release coil of the ordinary starting switch, and in parallel with the main supply. If, now, the main lever be gradually moved from step to step the motor will start, but if moved suddenly, so that at any time there is a large rush of current, the small coil will become demagnetised, and the auxiliary handle will fly back, and the whole operation must be started again. In a similar manner, other makers have devised various ratchet forms of attachments for operating the starting lever. This device is a distinct advance on the differential arrangement just described, for while in the former the time of starting is uniform over the whole range, in the ratchet type of switch a most important condition is fulfilled, and the lever rests for an appreciable time on each contact, and the break between contact and contact can be made very rapid. The worst feature about these ratchet type switches generally is that the parts being complicated some of them have to be put at the back of the slate, and there is no easy method of getting at them in case repairs are necessary. Some makers put the ratchet gear at the back, and some the electrical or contact part. It is questionable if either arrangement possesses any merit over the other. It is essential that the contacts should be examined from time to time, in order that any effects of burning may be made

Digitized by Google

good, while at the same time the ratchet gear is liable to get out of order, and should therefore be continually inspected. Notwithstanding this drawback of hiding part of the gear, the switch posseses undoubted merits, and if well made should be capable of fulfilling its functions satisfactorily.

In all these switches there is a great necessity to see that the resistance coils are well wound, and, therefore, as it is desirable to prevent any tendency to buckling, the adoption of a type of switch in which the coils are surrounded with sand is not to be condemned. In this case, however, the sand should be removed, and the coils thoroughly inspected before the switch is mounted, for while the sand will serve a useful purpose it will also hide any defects which should be sought for before the apparatus is put to actual work. The writer fully admits the usefulness of sand, but at the same time, if porcelain mandrils are employed, good resistance wire used, and the whole properly mounted, there is no necessity for any substance such as sand, and the apparatus is easier of proper inspection, and any fault which may develop can be seen and put right without any trouble.

In the cheaper form of switches the contact pieces are generally made permanent. This is a great mistake, and it would be well worth the additional money to have them made renewable. Care should also be taken to see that the pressure of the lever on the contacts can be adjusted if necessary. Above all, attention must be directed to seeing that the switch is fully equal to its work, and if a 5-h.p. switch, for instance, is ordered it should be distinctly understood that 5 e.h.p. is not meant, but 5 b.h p. In none of these switches is much attention paid to arranging the amount of resistance between the various steps, and, therefore, if the motor to be controlled is of any size, with the order for the switch should be given information as to whether the machine will customarily start up light or under load.

With the higher priced starters the control is usually by means of electrical solenoids. This is a great advance on either the magnetic control of the differential type switch we have already described, or on the ratchet device. One of the great benefits that is to be attained is that with solenoidal control only a small shunted current need pass through the actual contacts of the switch, while at the same time a more flexible and perfect piece of apparatus generally is the result. The solenoidal type is of rather restricted use, but lends itself to an infinite arrangement of the parts, and it will be advisable in this regard to study the construction of switches actually on the market.

In the majority of instances the solenoid switch is arranged so that the current first of all passes through a main solenoid-controlled switch, which when closed causes the contact lever to move from step to step; the current that passes through the lever may be the main current or a shunted current only. In the former case the switch then acts in the usual manner, but if a shunted current only flows through the contacts, the amount of resistance in circuit with the main path is cut out by subsidiary solenoidal switches. The principle is well illustrated in the switch shown in Fig. 3, which may be considered as a forerunner of the solenoid switch. The figure shows a slate slab, on which are mounted a number of knife-type switches in a line, also a small no-volt release coil in the upper left-hand corner, and below it a maximum release or overload preventer. The principle on which the switch is designed is the familiar one we have already dealt with—that if the current has a choice of two paths which have great difference of resistance between them, the majority of the current will flow through the path of low resistance. The armature external resistance is connected up with the various switches, so that when the first switch is closed all the resistance is in series with the armature circuit; when the second switch is closed, a certain part of the resistance is cut out, as this switch opens a path through the resistance at a point nearer to the armature. The current may all flow through the second switch, or part may flow through the path of higher resistance offered by the first switch—this is immaterial. The third switch cuts out more resistance, and so on, until when the last switch is closed the armature circuit is directly connected across the mains, and all the resistance is cut out.

This switch is not automatic in its action, and differs therein from the solenoid type of switches; apart from this it possesses some very good features. In the first place, slow motion is attained, as it is impossible for any operator to close the switches instantaneously, and it is equally impossible to close the switch in the wrong order. This is prevented by a special interlocking arrangement, and the switch is also arranged so that should the automatic no-volt release or overload preventer come into action, all the switches automatically open. The second good point is that the break from switch to switch—the equivalent of from contact to contact in the ordinary type of starting switches—is a quick break, and a specially good point is that the break occurs on parts specially adapted for it—viz., between the blades and the contact pieces of the switches—and there is nothing like the same tendency for the arc to be maintained, or for burning to take place, as there is with the ordinary flat surface contacts of a step switch. It will also be noted that the requirement that the time spent in operating the switch should be chiefly used while the lever makes contact with the various steps and not during the different breaks is fulfilled, and that there is ample time for the armature to attain the speed corresponding to the value of the current supplied while the operator is releasing

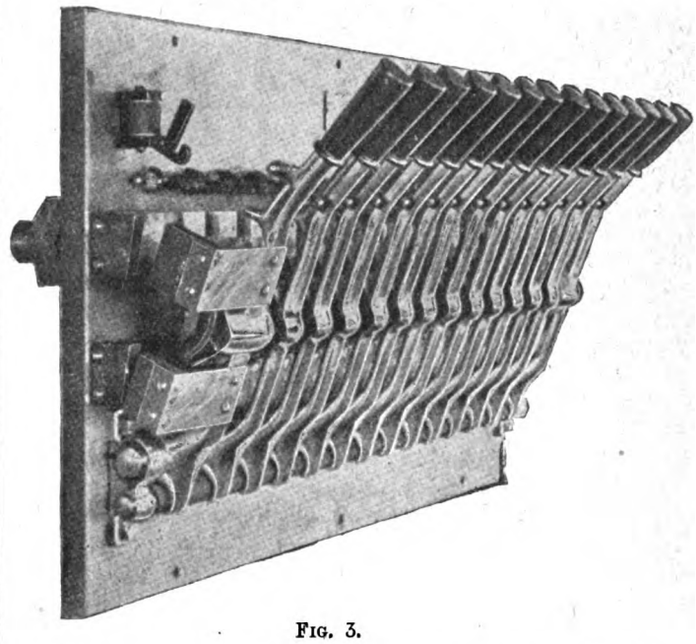

FIG. 3.

his hold on one handle and taking hold of the next in operating this switch.

TO CORRESPONDENTS.

All Rights Reserved. *Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.*

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

OBSOLESCENCE.

We do not know who imported the terms obsolete, obsolescent, obsolescence into financial discussions upon electrical undertakings, but whoever he was, either his imagination was defective or the immediate object served his purpose. Usually the usage comes to the effect—of course, from an opponent—that a municipal authority is not running its concern in the proper manner—not making sufficient allowance for depreciation. If you mildly suggest that the sinking fund is really a depreciation fund, you gain no credence, and at the next speech or in the next article the formula is repeated—insufficient allowance. It must have been a grand acquisition to the opposition when someone brought out the idea of obsolescence, and it has done duty ever since. The poor, much-abused authority is condemned upon every possible and impossible count. The good old English custom of looking upon a man as innocent till he is *proved* guilty has gone by the board. We now assume guilt, and will not admit innocence. The authorities take up duties which we think ought to be rigidly outside their sphere of operations. Having undertaken these duties at the behest of the majority, it is not within the sphere of our operations to assume ignorance or incompetence to organise and carry them out successfully. It is not within our sphere to interpret their actions in a different manner to the interpretation put upon the actions of a company. We ask then, When, where, and in what manner obsolescence has in days gone by been accepted in the working of companies? We are rather given to archæological studies, but the term is new to us so far as it applies to company working. We never heard of a factory or railway company being expected not only to depreciate, to put aside for reserve, etc, but also for obsolescence, and it seems to us that to do so would partake of foolishness. The London and North-Western Railway did not scrap their old engines when Webb's compound was introduced. The improvement of a type of machine has never been taken to indicate that all users of the unimproved machine must scrap what they have got in order to instal the new arrival. Further, if there is anything in this cry of obsolescence, it is ten thousand times more important in the organisation of competing concerns than in those that are of the nature of monopolies. Our conception of the case as concerns municipal authorities is this. Their large undertakings are generally of the nature of monopolies. Assume for a moment such an undertaking as a tramway scheme—where there is no horse or competing tram system—assume the design for the undertaking to be in competent hands, the material and apparatus fully up to date. The income and expenditure is estimated upon the use of *this* material and apparatus—its life, its effectiveness, its economy, its everything is taken into account, and we cannot see why further you should take into account possible improvements that may or may not be introduced during the years to come. Those who contribute the income have the benefit in the years before the improvement is introduced, and so gain by early enterprise. The loss in efficiency is generally small, and only comes into play, and then only comparatively, during the later years of life; the gain, on the whole, averages out all right. Assuming materials and apparatus to fulfil the expectations they were estimated to fulfil, where does obsolescence come in? Simply like this. An opponent comes along years after the original installation commenced work, says improvements have been made; things can now be done more economically and on a bigger scale; you are losing so much a year by working as you are working, compared with what would happen if you worked as we would have you

Digitized by Google

work. Unless there is an absolutely new departure, the natural obsolescence, old age, out-of-datism is allowed for in the first instance, and, therefore, need not be allowed for two or three times over. If the idea of obsolescence be pushed to extremes, it forbids all work or all progress, for we cannot conceive of machinery or systems not being improved. If the authority or company is so old-fashioned as not to accept the improvements made when extending the business or making renewals, the authority is to blame; but because a man says "I should not do that or use that now if I was starting," is no proof that originally he ought to have waited or to have estimated differently to what he did.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

XII.—On Competition.

My Dear Young 'Un,—I beg to acknowledge receipt of your last letter, the contents of which made me chuckle. You *were* in a paddy when you wrote! I imagine that if you had had the gentleman you refer to within your power, you would have torn him up and thrown him away. Failing that, you sat down and gave me the biggest treat I have had for a month.

And what's all the rumpus about? Just because "a lout who never passed his Seventh Standard, and whose highest engineering diploma is an Ordinary South Kensington Machine Construction Certificate," to quote your own graphic epitome, has been promoted to the marking-off table when you thought you were going to get there, you howl as if you had buckled your front wheel and smashed three ribs in a cycle spill. The best I can hope for you is that you haven't exhibited any traces of this nasty temper to the fellow or to any of the other shopmates. Jealous words are like boomerangs—the harder you thow them, the quicker they come back and hit you. And another thing—don't despise a man because he has not had the same educational opportunities as you have. You can't judge a cigar by the picture on the box; neither can you estimate a man by the school he went to. I don't think, after the letters I have previously written, you will accuse me of underestimating the value of education, but I would point out to you that most of our pioneers were indifferently-educated men, and that even nowadays from the heads of our engineering firms (and not sleeping partners, either) can be picked out men who look woebegone when you mention calculus, but who know what organisation and initiative mean. When they want pure science they hire a tame theorist, and supply the gumption themselves.

Your best mental attitude will be that of comparative analysis of your own ability and that of the man who has beaten you. Schedule your attainments: (1) theoretical groundwork, (2) accuracy, (3) energy, (4) stamina, (5) resource, and so on. Give yourself and the other fellow comparative marks; tot them up, and see which is the better man on analysis. You may be pluming yourself on some out-of-the-way virtue and neglecting the rest. You had better cast back, and see if you can recollect any time when some action of yours gave your foreman a strongly unfavourable opinion of some part of your character. A foreman may try to be as honest as he can, but his knowledge of the men under him is largely experimental, and some unfortunate accident may have created a bad impression which it will take some time to eradicate. If you can spot the mischief, lay yourself out to neutralise it. It is no good chucking your tools about, and saying that so long as the foreman has favourites it is no good trying. You will have favourites when you become a foreman, unless you have got batter pudding where your brains ought to be. The point is to make yourself one of the favourites.

Too many fellows when they are in the shops make the same mistake that astronomers used to fall into. Before the days of Galileo and Copernicus we on this planet had a very inflated notion of our own importance. The sun used to circulate round us, and the stars used to come and play bo-peep with us. When Galileo came along and blared out the truth, the principalities and powers that then were got so mad that they never let up on Galileo until he had signed a document to the effect that he had made a slip of the tongue, and was sorry he had ever had the audacity to be born. But the truth remained all the same. We aren't so big as we thought we were. In the same way, some fellows think that their shopmates, their foreman, the works, and the engineering firm exist for their benefit, and get wild if everything doesn't go as best suits them. If you fall into this error, you must at once readjust your mental centre of motion. You are not a fixed star. You are only a planet; and if you don't do your work and be civil, you will soon be a shooting star. Other fellows must have their chance as well as you; and if other fellows—whatever their initial position may have been—use their chance better than you, don't grumble when you find them walking on your head.

Again, one man oftentimes gets a pull over another because he is more adapted to the particular set of circumstances. A wedge gets on because it has got a sharp nose followed by a strong flank. A piece of straight bar steel may have more substance than the wedge, but it won't push along at a quarter the rate, because its substance isn't properly disposed for the work. When you are in competition (and when are you not?) you must study your circumstances and adapt yourself to them. You may depend on it your employer will soon size you up, and if you are the tool for the work he wants done he will push you forward. There are two old saws applying to competition which I recommend to your earnest consideration. The first, which I strongly agree with, is "One man's meat is another man's poison." You are feeling sick because the other fellow has got the job. He is probably as pleased as a dog with two tails. Just store that up in your memory against the day when you succeed against other competitors. Don't gloat; the others are feeling bad enough already, and they will put something into your tea if you aren't careful. No battleship goes forth to meet the midnight foe with the deck lights burning. It isn't safe to laugh much at other people's expense in this wicked world, and if you *must* do it, get into the middle of a lonely field and put your handkerchief in front of your mouth before you begin.

The other proverb, which strikes me as a highly immoral one, is—"All's fair in love and war." Most people add, "and business"; but I venture to suggest that everything isn't fair. Some men seek to appreciate their own virtues by telling lies about those of others. It is common to lay snares in order to trap competitors. I know that engineering is in a great state of depression just now; but if it is necessary to do dirty gutter business like this in order to make a livelihood, I almost wonder whether the time has not come to see if a clean living cannot be made at navvying.—Yours,

The Old 'Un.

DESCRIPTION OF THE ELECTRICAL EQUIPMENT OF AN ENGINE WORKS AND SHIPYARD, WITH NOTES THEREON.*

BY H. O. WRAITH, ASSOC.MEMBER.

(Concluded from page 556.)

Starters.—Wherever possible, liquid starters and controllers were used. For non-reversing machinery a type was used with an automatic release, which merely consisted of a solenoid coil, in the shunt circuit, which held the dipping blade down. If current was shut off the blade was released, and a spring caused it to fly up. No overload release was used. These were tried on some metallic starters, but were found to be too "kittlish" for use in a place where non-stoppage of work is essential. A momentary overload which would not seriously affect a motor, and is of too short duration to blow the motor fuses, makes the overload release act, and stops the motor until somebody can be found who knows where to look for the cause of stoppage

* Paper read before the Leeds Local Section of the Institution of Electrical Engineers.

Digitized by Google

and how to put it right. A fuse is reliable enough to act when the overload is serious, or of long duration. Each motor was fitted with a double-pole main switch, double-pole fuse, and starter, in addition to the double-pole fuse on the distributing board, so that there were two sets of double pole fuses to safeguard each motor. The author does not deny that there are excellent metallic starters on the market, although many of them are badly arranged, badly divided off, and too light for their work. There is, however, no fault to be found with some, on whatever ground, as a starter. It is not, however, on technical grounds that the author prefers liquid starters, as on the general grounds of the use to which they are put. As a rule it is inevitable, without over-manning the electric staff grossly, that in a works of this description motors have mostly to be started by unskilled men, or, rather, men who know nothing about electrical machinery. Even if the shop foreman is the only non-electrical man allowed to start a motor, there are plenty of shop foremen who are quite capable, after dozens of lessons, of putting in the main switch, cutting out all the resistance with one vigorous shove, or even of reversing the order of those operations, and then cursing because the motor does not start. The liquid starter, to the uneducated mind of the ordinary workman, more resembles a stop valve. He can see something is happening by the bubbling of the solution. If it bubbles too much he is moving too fast, if it doesn't bubble at all, and the motor doesn't start, something is wrong and he sends for an electrician. But with the majority of metallic starters a handle projects in some form outside a closed box, and the man starting the motor cannot see anything going on, beyond flashing at the contacts, which probably takes place under any circumstances. So he doesn't take so much interest, and moves the handle at the pace which seems most expedient to him. In addition to this the liquid starter can be constructed in a much simpler manner, and with fewer parts to get out of order, than a metallic starter, which makes repairs easier and cheaper. In the case of cranes and other reversing machinery the same thing applies. The liquid controller, to the mind of a man accustomed to steam, resembles a stop valve, and if he treats it as he would a steam-engine stop valve he will not go very far wrong. For cranes, etc., the tramway controller is probably as capable of withstanding rough usage as any liquid controller, but its initial cost is high, which will, where low prime cost is an object, throw the balance in favour of the liquid controller. A great advantage of the liquid controllers is that all making and breaking contact is done on the surface of the liquid, and so sparking at metal contacts is avoided. The chief objection to the liquid starter — viz., that the solution must be of the necessary strength and quantity, and that it is liable to creep and make things in a mess—has no grounds in a works where an electrical staff must be kept, and where someone can be made responsible for examining and attending to them all at stated intervals.

Cranes.—The electric cranes in use were all in the engine works and brassfoundry, as follows:

Situation.	Maximum load, tons.	Motor B.H.P.			Controller.
		Hoisting.	Travelling.	Traversing.	
Brassfoundry	5	6	4	3	Liquid.
Erecting shop	30	15	10	5	Metallic.
,,	10	6	4	2	Liquid.
Boiler shop	30	14	8	4	Liquid.
Unloading gantry	20	15	10	4	Liquid.
Boiler shop	40	30-h.p.	single motor		—
,,	10	20 ,,	,,		—
Erecting shop	20	15 ,,	,,		—
Turning shop (2)	¾	1	1	—	Metallic.
Upstairs fitting shop (2)	¾	1	1	—	Metallic.

Besides these there were one or two small hoists in the shipyard. All the three-motor and two-motor cranes were fitted with automatic brakes, to act when current is shut off. The trolley wires, except in the case of the brassfoundry, where an old solid rod trolley wire was used, were of stranded hard-drawn copper, and were both mounted on one side of the shop, to save the expense of a double set of brackets, and to minimise the number of holes drilled in the girder work. The current collectors were all of the sliding shoe pattern, which lifted the trolley wire off the brackets as the crane passed along. Collectors of the wheel type were tried, but these were found very liable to jam and wear the trolley wire badly, and were all replaced by long shoes. At first the crane circuits were protected by double-pole fuses only, but as one or two short-circuits occurred, owing to careless men putting oil-cans, etc., down on the two trolley wires and bringing out the generator circuit breakers in the power-house, all crane circuits were protected by overload circuit breakers. After they were fitted, they answered perfectly satisfactorily. The author thinks that all crane circuits, where bare trolley wires are used, should be fitted with automatic overload circuit breakers, as in the case of a dead short, fuses heavy enough to stand the ordinary load act too slowly, and there is a danger of bringing out main circuit breakers when these are used. In the case of ordinary motors, driving tools of any kind, a circuit breaker is unnecessary. He is unable to remember a case of a short-circuit on a motor other than cranes bringing out the dynamo circuit breaker, and the rareness of the occasion justifies the leaving off of circuit breakers on all circuits (other than crane circuits). Stranded trolley wires were used in preference to solid ones, because of the greater ease of handling and repairing. However badly a stranded wire is burnt by short-circuiting, it is possible to patch it up, so that, at any rate, it can be used till a new one can be run, whereas if a solid wire gets burnt through, or nearly through, the chances are it cannot be used at all again, and the shop cranes have to stand till a new one is put up. It was the author's practice always to keep ready to hand a spare pair of trolley wires for the erecting and boiler shops (which were of the same length), for the cranes are the life of a busy shop, and without them the shop soon comes practically to a standstill.

Spares.—In converting a works of any size to electric driving, as a rule not nearly enough attention is paid to the matter of spare gear. No man nowadays hesitates to insure his premises and goods against fire, and to pay heavy sums annually, so that he may not lose, or that his loss may be a minimum, in the case of fire breaking out. At the same time he may be firmly convinced that a fire could not possibly happen in his works. Spare parts are an insurance premium, paid to cover the risk of serious loss from stoppage of work due to breakdown of machinery. Thirty or forty years ago, and even with some firms to-day, steam-engines and other machinery were only in very exceptional cases built so that the parts of any two machines were interchangeable without an excessive amount of fitting, even though the machines were supposed to be exact duplicates in every dimension. But with present-day electric, steam, or gas machinery, as, of course, with many other classes of present-day machinery, all parts which are likely to require renewal, or are likely to break down in case of anything untoward happening, can be made exactly interchangeable for machines of the same type and size. For the generating sets a stand by plant is necessary, and this is a complete set of spares by itself, so that, in the case of the dynamo, no spare armature is wanted, nor need any other spare parts be kept, except small parts, a set of piston rings, a complete set of governor or other springs, carbon brushes, and any other special part that might require renewal. It is advisable, where possible, when deciding on the correct plant to buy, to keep the units of exactly the same size and type, and, moreover, of such a size and type that it will suit for any future units that may have to be laid down for possible extensions. Then one set of spare gear will fit each and all of the units. This is not always possible, but unless there is a strong reason against it, the units ought to be kept identical, for not only are spare parts reduced to a minimum, but the attendants get more familiar with, and handle more easily, a number of identical units than a heterogeneous collection of machines. A spare armature should be kept for every different size motor in the works. Great improvements have lately been made in the manufacture of motors, and as a machine they are now, mechanically and electrically, perfectly sound. But accidents will happen As an instance of an accident, the author has known cases of a playful lad throwing a nut, or

Digitized by Google

some such handy missile, at an equally playful companion, and hitting the open door of a motor, the nut getting jammed between a pole-piece and the armature, fireworks and a stoppage resulting. As everybody can appreciate, very serious losses may result from the stoppage of even a small section of a shop, if it is a case of rewinding an armature or waiting for a spare one to be sent off from the manufacturers, whereas even in the cases of motors up to, say, 30 h.p., it is, as a rule, only a case of waiting one to three hours to put in a spare armature that is ready to hand. A small, though important, point about all armatures is that the pulley should be fixed on by a set-screw and feather key, or in some manner so that it may be easily removed from the shaft, to prevent loss of time in getting out a stubborn-driven key. It therefore behoves the buyer of plant to use as small a number of sizes of motors as possible, and have a spare armature for each size. It is better to underload a motor in a case where only one or two of the correct size would be wanted, so as to keep to the standard size and have the use of the standard spare gear for that size. Spare brush gear is also a necessary for each size of motor, and may save a good deal of time in renewal work, which must necessarily be done in overtime, when the shop is not working.

Recording of Loads.—The methods that were adopted for registering current generated and consumed were chosen so that as much information as possible might be obtained from the readings taken, and at the same time the instruments and readings might be easily understood by the working staff. The system consisted of three compound-wound dynamos, feeding in parallel on to a pair of common main 'bus bars, off which 'bus bars all circuits were taken through double-pole switches and fuses. An automatic circuit breaker, with magnetic blow-out arrangement, protected each generator. The current fed on to the 'bus bars by each of the three generators was registered on a recording low-potential ammeter on the main switchboard, with a paper speed of 1in. per hour. As the shipyard was worked as a separate department from the engine works, the switches for the shipyard circuits were all mounted on a separate panel of the main switchboard, and for the purpose of determining the consumption of current by the shipyard, an ammeter of the above type, with paper speed of 1in. per hour, registered the aggregate current passing to this panel. A portable ammeter of the same type, with a paper speed of 6in. per hour, was kept for the purpose of testing loads on motors, or any particular circuit, etc. This speed, $\frac{1}{10}$in. per minute, was ample to show the exact durations of the load, as well as its magnitude, and the instrument was very useful. The paper recording instrument was used in preference to the summation type for recording the dynamo current and the current used by the shipyard, because of the greater amount of information to be obtained from the charts. On them could be traced the exact nature of the load at any minute of the day, and any apparent irregularity could be enquired into. Also it acted as a check on the regular rotation of running of the three dynamos, the load during portion of the day being small enough to be carried by two machines, the third being put in when the lighting load came on; and it was an object, as far as possible, to distribute the work evenly between all the machines. All records were filled in books kept for the purpose, the working up of the results being extremely simple, and done as follows: The total area enclosed by the line marked by the pen and the zero line, was measured by a planimeter registering in square inches. This area, multiplied by a constant depending on the paper speed, the breadth of the paper and its graduations, gives the total ampere-hours. Thus, suppose the paper speed is 6in. per hour, paper breadth is 3in. and graduated to 200 amperes, area of card 12·5 square inches

$$\left(12{\cdot}5 \times \frac{200}{3} \times \tfrac{1}{6}\right) (= \text{total ampere-hours}) \times 225 \text{ (voltage)}$$

$$= 32{,}500 = \text{total watt-hours.}$$

This method of recording, although it may be open to the charge that it is not as accurate as if the watt-hours were recorded direct on a watt-hour meter, is, nevertheless, accurate enough for all purposes, and possesses the advantages that it is simple and one can see exactly where the various loads are coming from and going to.

Relation of Current Demand to Rated Motor Power.—In the shipyard, where there was only one small two-ton crane, the aggregate brake horse-power of the motors of all kinds employed was 553. Taking four amperes at 220 volts as being required to give 1 b.h.p. from the motor, the total current required if all the motors were working simultaneously at full load would be 2,212. Let us call this the rated full-load current. Then from observations taken

$$\frac{\text{Maximum actual demand by motors}}{\text{rated full-load current}} = \frac{800}{2{,}212} = {\cdot}362.$$

In the engine works and brassfoundry, etc., the aggregate rated brake horse-power of the motors was 504, but this included

Two	30-ton	three-motor	cranes.	One	40-ton	single-motor	crane.
One	20 ,,	,,	,	One	20 ,,	,,	
One	10 ,,	,,		One	10 ,,	,,	
One	5 ,,	,,					

The engine works rated full-load current was, therefore, 2,016 amperes, and the actual maximum demand about 700 amperes. Therefore, for the engine works,

$$\frac{\text{Maximum actual demand by motors}}{\text{rated full-load current}} = \frac{700}{2{,}016} = {\cdot}347.$$

Generating and Coal Costs.—In giving tables and figures for generating costs, etc., the author does not claim that the figures are by any means what they ought to be, although they will probably compare favourably with a great many large private installations in works. They serve to show, however, in this particular case, wherein the defects in the generating plant lay, and in a general way, on which the author wishes to lay stress, the enormous importance, not realised by a great many private owners of installations, of collecting and tabulating all possible data, so that any weak point in the installation or possible improvement may be spotted at once, and acted on as may be necessary. Of course, in all public or private supply stations where the business is solely generation of electric current, accurate figures and data are kept and published, and the general run of the cost figures for generating current are well known and accessible to anyone who reads the weekly technical electric papers. Unfortunately, or fortunately, the installation which the author has made the basis of his remarks was put down piecemeal, and prior to his advent on the scene it was deemed advisable to lump all electrical generating and upkeep costs with the ordinary works maintenance cost accounts. In addition to this, the feed-water system for supplying water to the steam-boilers for driving the electric plant was common to another boiler used for driving steam hammers, feed-water pumps, and a steam-driven set of accumulator pumps. Steam from the boilers raising steam for the electric generators was also taken for driving two air-compressors of about 25 h p. apiece. The whole of the water softened was not used for the electrical plant boilers, some of it being sent down to the shipyard for feeding an auxiliary boiler there. In spite of these difficulties, the author took all possible readings and observations with the object of ascertaining exactly the proportion of coal and water used for the generating of electric current, and managed to fix down pretty accurately the proportions he wanted. Although, therefore, he cannot say that the figures are scrupulously exact, they are reliable, and serve the purpose for which they were intended—viz., to find out, in detail, what the generation of electricity was costing the firm, and whether the figures arrived at represented the best practice under the circumstances. The figures given are not picked in any way, but are taken from the electric costs book, and are taken from five continuous months during which both double—*i.e.*, night and day—and single—*i.e.*, day only—shifts were worked.

GENERATING COST DETAILS PER BOARD OF TRADE UNIT.

Month	Sept.	Oct.	Nov.	Dec.	Jan.
Shift	Double	Double	Double	Single	Single
Coal	·441	·407	·345	·422	·421
Water	·026	·022	·022	·023	·024
Wages	·082	·084	·084	·117	·115
Stores and repair material, etc...	·013	·027	·105	·053	·058
Wages for repairs	·077	·092	·092	·087	·090

Works' costs	·639	·632	·648	·702	·708
Taxes, rents, and general charges	·092	·101	·117	·135	·130
Interest and depreciation	·202	·186	·188	·280	·289
Total cost	·933	·919	·953	1·117	1·127

The capital outlay per kilowatt was £23. 4s. The average price paid for coal was 11s. 6d. per ton. Now let us examine these figures. The cost per unit of coal in September is nearly 50 per cent. of the total cost per unit. Referring to the coal sheets, we see that the total coal used during the month for electrical purposes was 314·1 tons. The total output of the plant (double shift) was 98,274 Board of Trade units. This works out at 7·175lb. of coal per Board of Trade unit, or, taking 82 per cent. as the average combined efficiency of engines and dynamos, 4·39lb. of coal per 1 h.p. per hour, or, again, 5·35lb. of coal per electrical horse-power per hour. This seems to be higher than it ought to be, a thing the author expected to find, for, as before said, the feed-water heating arrangements were very defective, and there was a run of about 100ft. for the main steam-pipes from the boilers to the engines, and this, although the pipe was covered with non-conducting composition and run inside the building, must have been a source of considerable condensation. The cooling tower had also for some time been too small for its work, and, in consequence, the condensing water returned to the condenser at too high a temperature to keep a proper vacuum, which would, of course, cause a rise in the coal consumption. However, an investigation was made to see whether any immediate steps could not be taken to reduce the coal consumption, with the result that it was found that the mechanical stokers on the boilers, although they reduced smoke, were, from whatever cause, throwing the coal badly, a good deal of hand firing having to be done, as well as admitting too much air to the furnaces. They were, therefore, as hand firing could be done without increase in the number of firemen, dismounted and hand firing resorted to, with the result that in October the cost of coal per unit is reduced by nearly 8 per cent., the coal used per electrical horse-power per hour in October being 4·03lb. on a total output for October of 106,641 Board of Trade units. This is an improvement, although the figure for coal consumption was by no means as low as it ought to be, and may be, with a well-designed installation. In November the coal cost is still further reduced. No special reason can be given for this, except that the condenser was retubed at the beginning of the month. The cooling water was extremely hard, and the inside of the condenser tubes very speedily became coated with a very hard flinty scale, very difficult to remove. In fact, the author has not come across a tube brush or scraper that would efficiently cope with it, and the condenser had to be periodically retubed. The coal used per electrical horse-power in November worked out at 4·18lb. per hour, on a total output of 104,977 Board of Trade units. None of the other figures for the first three months call for any special comment, except, perhaps, the high figure for stores and repair material in November. This was due to two new sets of piston rings being charged, and also examining and overhauling the cylinders of three engines in that month. Depreciation was calculated at 5 per cent. on the total capital outlay on generating plant. At the end of November the night shift was knocked off. First let us see what reduction is made in the output of the electrical machinery. The average output per month for September, October, and November, when two shifts were running, was 103,297 Board of Trade units. The average for December and January, with only a single shift, was 71,580 Board of Trade units, or a reduction of, roughly, 30 per cent. of the output due to the night shift being stopped. It may be objected that December and January are, owing to the holidays, broken months, and, therefore, the comparison is hardly fair, but that does not affect the broad principles which the author is seeking to prove. As a matter of fact, as will be seen from a comparison below, the actual number of hours during which the electric plant was running was about 60 per cent. in December of what it was in November. This high proportion was due to a large amount of overtime worked during December in the shipyard, and would be expensive running for the electric plant. Returning to the cost sheet, we see that in December and January the coal cost per unit has risen again to nearly what it was in September, although it is not such a large proportion of the total cost (about 35 per cent.). To see exactly how this extra coal used was to be accounted for, and what proportion went to banking up, etc., the coal used in the electric plant boilers was accurately measured for every hour of the day for a number of days, as well as the output of the dynamos during each hour of the day. The figures given below represent the mean of the daily readings taken.

Coal Used during Different Portions of the Day.

—	Before 6 a.m.	6 a.m. to 8 a.m.	8 a.m. to 9 a.m.	9 a.m. to 12.	12 to 2 p.m.	2 p.m. to 5 p.m.	5 p.m. to shut down.	Banking up.
Total lbs. coal used.	2,987	3,920	933	3,593	2,659	3,920	1,960	1,260
Total units generated.	97·5	714·25	163	882·92	318·25	870	335·5	—
Lbs. coal per E.H.P. hour	23	4·1	4·27	3·04	6·23	3·36	4·35	—

The shipyard breakfast time was from 8 till 8.30 a.m., and dinner hour from noon till 1 p.m. The engine-works breakfast time was from 8.30 to 9 a.m., and dinner hour from 1 to 2 p.m., so that 8 to 9 a.m. and noon to 2 p.m. were times when the load was light. The reason of the coal consumption being so high between 12 and 2 was that advantage was taken of the light load to clean out the boiler fires during that time. Now, during the actual time the plant was being used—*i.e.*, from 6 a.m. to the time of stopping—the total amount of coal used was 16,985lb., or about 80 per cent. of the gross total, for a total output of 3,283·92 Board of Trade units. This gives us 3·91lb. of coal used per electrical horse-power per hour, or taking into account the coal used in banking up and restarting 4·71lb. of coal per electrical horse power per hour, as against 4·56lb. of coal per electrical horse-power per hour used in October and November, the two months of double shift, during which the boilers were being fired under similar conditions. During the period of double shift the night load was about five-twelfths of the day load, so that these figures show that the extra coal used per unit in banking up and restarting is not very much more than the increase per unit of coal used during double shift due to the decreased efficiency of the working of the night load. We may expect that had the night load while double shift was running been the same as the day load, the coal used would have come out at about the 3·91lb. per electrical horse-power per hour given above as the coal actually used during working hours. We see also that wages for running the plant were increased about 40 per cent. per Board of Trade unit, rents and general charges about 28 per cent., and interest and depreciation about 48 per cent., due to the night shift being stopped. The following comparison shows the proportion in which the various items were increased or decreased by the stopping of the night shift.

Comparison between Double and Single Shift.

	November, double shift.	December, single shift.
Total output	100	70·5
Total hours run	100	60·2
Total cost	100	83·0
Cost per Board of Trade unit	100	117·2
Total coal used	100	86·5
Coal per electrical horse-power hour	100	121·1
Total water used	100	70·0
Total wages—Electricians	100	72·7
Enginemen	100	51·6
Firemen	100	100·0
Millwrights	100	101·0
Interest and depreciation per B.T.U.	100	148·9
Total labour per B.T.U.	100	116·0

The items of proportionate increase of cost on stopping the night shift are, in order of importance, interest and depreciation, coal and labour, which are, of course, just as we should expect them. The labour and coal are not very excessive when double shift is running, in spite of the defective condensing and steam-pipe arrangements mentioned before, but the change in the total cost when single shift only is worked is very marked, which goes to show, what probably all present know, that the nature of the load makes very much more difference to the cost per unit gene-

Digitized by Google

rated of a plant than any mechanical defects or perfections of the machinery used. The author does not mean to imply by that that not much attention need be paid to mechanical and labour-saving details. Very great attention must be given to all details of an installation, so that all apparatus used is of the very best and most economical type, but the refinement of cost-saving machinery may easily be carried so far that some of it saves less than it costs in interest and depreciation, especially in the case of poorly loaded plant, and there is no doubt that this happens so in the case of a great many central stations. In far too many cases where it is decided to instal electric plant the subject is not understood by anyone in the employ of the works owners, and the matter is placed in the hands of a well-known firm of electric contractors. They will probably supply machinery satisfactory enough in itself on the scanty information furnished, but as often as not, not the most suitable class of machinery for the particular circumstances. To get the best results the matter must be investigated thoroughly by an employé of the works owner, who knows exactly, or can find out, the system under which work is carried out, the nature of the probable load on the generating plant, in general, knows the particular set of circumstances under which the plant will have to work, and, of course, knows intimately all the different points about generation of electricity in all possible manners—steam, gas, water, etc.—and transmission of power by electricity. Above all, must all possible data be tabulated and all costs kept in such a manner that all fluctuation in loads, consumptions, and costs may be readily seen and the cause investigated, and, if necessary, remedied. This is a most important point. Thirty or forty years ago people would stick down a set of boilers, steam-pipes, and engines and connect them up to their shaftings, and never up to the present day had they the faintest idea what work they were doing, or what they were costing. But that was in the days when fortunes were made. Nowadays manufacturers have to take orders at under cost prices (or so they say), and it behoves them to see that, among other things, their methods of generating power are the most economical and, therefore, efficient possible. As an instance, a few months ago the author had the pleasure of advising the head of a large works to adopt electric driving. On going roughly into the question, it was clear that a saving of at least £2,500 per annum could be made in the works expenses with a capital outlay of about £8,000, and there must be hundreds of works in the country where similar results could be arrived at. In this case the owner had not much idea how much his power was costing him, beyond the fact that he was burning so many tons of coal per annum, and some of that in heating furnaces. Another very general and also fatal mistake that is made in converting large works to electric driving, is converting by degrees, and not allowing in the first instance for the maximum proportions to which the installation may extend. Electric driving is now past its infancy, and its performances and capabilities are pretty well known, but, in spite of that, the man who is thinking of converting the whole of his works, taking, say, 2,000 h.p., will be distrustful, due to ignorance, and will convert a portion of the works, taking, say, 200 h.p. Instead of laying down his power-house, boiler plant, generating units, etc., on the assumption that ultimately he will require 2,000 h.p., he sticks down a little 200-h.p. dynamo in a corner of the shop out of the road, and makes his arrangements so as to spend as little as possible over his "experiment," instead of employing somebody who knows intimately all about his little "experiment" and laying down proper plant. The consequence is that when he finds electric driving seems to be quite practical and much handier than steam, that nothing explodes or misbehaves itself, although, perhaps, he has only a general idea that he has made any saving in £ s. d., he decides to convert the rest of his works, and must then face two alternatives: (1) add to the plant he has already bought, without regard to its suitability for the larger installation, and so sacrifice economy in running expenses; or (2) disregard (partly or altogether) the plant he has bought, and lay down a complete and up-to-date generating plant and station. In this case his total capital cost is a good deal greater than it would have been had he laid the first plant down on the assumption that he needed 2,000 h.p. altogether. Of course, the idea of such a man is that the "experiment" may be a failure, and have to be pulled out again: therefore, looking to such a contingency, he wishes to keep his possible loss as small as possible, but, as was said before, electric driving is now well past the experimental stage, and electric machinery, as now manufactured, is as reliable as, or more reliable than, any other kind. It only needs proper knowledge of the local circumstances to be able to say definitely what is the most suitable plant to lay down in any particular case, its prime cost, and the cost of running it.

Adaptability of Electric Driving.—As a very good instance of the pliability and adaptability of electric driving, rather than with any idea of its being in any way extraordinary, the author introduces a disastrous fire which occurred in the engine works in September, 1901. It was discovered about 5 o'clock in the morning, when a day shift only was working, by men coming in to fire up the boilers, and the net result of it was that a great portion of the engine works was gutted. Fortunately, the power-house was unharmed, but the supply mains to the shipyard which passed along portion of the engine works roof were damaged. By 9 o'clock in the morning it was possible to get up to examine the shipyard cables, when it was found that very little damage was done, except that the insulation was all burnt off for a considerable distance and one supporting bracket was broken down. This was soon temporarily put in working order, and the supply to the shipyard resumed by mid-day. The engine works, however, was in a different plight. The whole of the small machine shop, erecting shop (containing the larger planing, turning, and boring machines), and portion of the boiler shop were gutted. Luckily, the new brassfoundry between the engine works and the offices was practically completed, and it was at once resolved to convert this into a temporary shop for the smaller machine tools, and let the large machine work out to neighbouring firms. A pair of $^{19}/_{14}$ was at once run to the brassfoundry building, wooden baulks and platforms were erected to support the necessary shafting, and the shafting put up in two sections with two 20-h.p. motors, which happened to be available, with starters, etc, to drive it. Lathes, etc., were wired for and put down with all possible speed. The motors were, without haste, ready to run within two or three days of the fire, and the shafting very shortly after, and, if necessary, all this portion of the work could have been ready in 48 hours. In consequence of electric power being available, therefore, a few machines which the makers had had in stock were running within about a week of the fire, while within three weeks nearly as much work was being done in the temporary building as had been done in the burnt-out small machine shop. The pliability of electricity was further illustrated in rebuilding the engine works, in the use of temporary arc lamps and clusters, and of portable saw benches, a tool largely used in ship work for sawing joists, flooring, etc. These portable saw benches have, in the works under consideration, almost entirely superseded hand sawing and hand adzing on ships in course of construction, with a large saving in cost.

Lighting.—Although in deciding on the number of arc lamps to put in a building each case must be considered from its own standpoint—that is to say, the reflecting power of the surface of the walls, any obstructions there may be, etc., have to be allowed for—the author gives below a few figures for the watts installed in arc lamps alone in various shops. He is inclined to be in favour of enclosed lamps, on the ground that they cost less in upkeep, although not so much light is obtained for an equal consumption from enclosed as from open type lamps.

Shop.	Approximate floor area (sq. ft.).	Watts per 1,000 sq. ft. of floor area.	Remarks.
1. Joiners' shop.....	6,000	1,100	All inverted arcs.
2. Marking-off loft ...	4,800	917	,, ,,
3. Turning shop.....	5,400	1,630	Enclosed arcs.
4. Erecting shop	13,200	583	,, ,,
5. Blacksmiths' shop...	7,200	460	Open arcs.
6. Boiler shop	13,200	500	,,
7. Quay shop	2,772	800	Enclosed arcs.
8. Plumbers' shop.. ...	1,850	600	,, ,,
9. Pattern shop.....	5,400	1,020	,, ,,

Digitized by Google

No. 1 is, the author thinks, the best illuminated shop he has ever seen. No. 3 is rather a dark shop, with a great number of belts. The arranging of the lamps was rather difficult in order not to leave any badly-lighted corners. In addition to the arc lamps, there were, in Nos. 3, 4, 6, 7, 8, a number of incandescent hand lamps for use on machinery, inside boilers, etc., where local light was required.

In conclusion, the author wishes to express his indebtedness to Messrs. W. Donford and Sons, Limited, for allowing him to publish the figures in this paper.

DUDLEY ELECTRICITY ACCOUNTS.

The accounts of the Dudley electricity department for the year ended March 31, 1904, show a total expenditure on capital account of £70,727. An abstract of the revenue account, together with the statement of electricity generated, sold, etc., is given herewith.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	4,177	0	4
Distribution of electricity	114	17	3
Attending and repairs to public lamps	298	3	0
Rents, rates, and taxes	385	10	10
Management expenses, salaries, etc	624	7	3
Special charges, insurance, etc.	49	18	2
	5,649	16	10
Gross profit carried to net revenue account	5,012	2	1
	£10,661	18	11

Cr. Income.	£	s.	d.
By sale of current per meter	9,230	16	2
Public arc lighting	1,120	0	0
Ditto incandescent lamps	196	18	8
Rental of motors, meters, etc.	54	19	4
Sale and repairs of lamps and other apparatus	9	18	10
Testing fee	0	10	6
Miscellaneous receipts	48	15	5
	£10,661	18	11

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T.U.			1,736,240
Quantity sold	Public lamps	112,117	
	Tramway company	1,035,021	1,526,713
	Private consumers by meter	379,575	
Quantity used on works			101,065
Total quantity accounted for			1,627,778
Quantity not accounted for			108,462

Total maximum supply demanded (kilowatts): trams, 850; lighting, 354. Number of public lamps: 56 arcs, 222 incandescents.

HACKNEY ELECTRICITY ACCOUNTS.

From the accounts of the borough of Hackney electricity department for the year ended March 31, 1904, it appears that the total expenditure on capital account to that date amounted to £246,575. Appended are abstracts of the revenue account and balance-sheet and statement of electricity generated, sold, etc.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.

TRADE NOTICES AND NOVELTIES.

Linolite Lamps.

We have received a copy of an interesting report on these lamps by Mr. J. S. Dow, A.C.G.I., who subjected eight of the lamps to an extended trial lasting 1,200 hours. The trial was made with a double object, the first being to see whether the reflector had any effect on the life of the lamp, and, further, to ascertain the average life and efficiency of the lamps. On the first point, the evidence is clear that the presence of the reflector close to the lamps, to which the distinctive name of Linolite has been applied, has no influence whatever on the life of the filament. Of the eight lamps under trial, one failed after 650 hours, but the other seven were still in operation after the 1,200 hours. The curves accompanying the report show that the average decrease in candle-power during the first thousand hours is about 15 per cent. The interesting feature from the consumer's point of view is the energy consumed per candle-power hour. At the beginning of the test the average consumption for the eight lamps was 3·75 watts per candle-power, the average watts per lamp being 47·13. At the end of the thousand hours' run the average watts had only increased to 47·21, which is an increase of ·169 per cent. This is considerably lower than the average increase with the ordinary type of incandescent lamps. In the same way the mean watts per candle-power rise from 3·75 to 4·40, being an increase of 17·95 per cent. This figure is also good, and leads one to the conclusion that either the Linolite Company are exceptionally successful in the choice of their filaments, or that the form of lamp has some influence on the life of the filament.

Street-Lighting.

The Reason Manufacturing Company, Limited, of 11, Victoria-street, Westminster, S.W., and Brighton, have specialised in street-lighting, and that they do not intend being left behind is evident from their latest catalogue, which includes much interesting matter, and is, moreover, exceedingly well printed. Accompanying are illustrations of a few examples of their recent progress in fittings for the purpose in question. Fig. 1 shows a three-way lamp bracket of the firm's "K 3" type. This fitting can be supplied with switches and fuses if desired, and is suitable for use with "A" and "B" type Nernst lamps or small enclosed arcs. Attention is particularly called to the new reflector lantern (Fig. 2). This is one of the latest developments for Nernst, incandescent, or small arc lamps. It can be supplied either with clear or frosted glass, and when two lamps are used there are no shadows. Another advantage of this lantern is the accessibility of the lamps and internal fittings, it being only necessary to unscrew the top finial to remove the cover. In the tramway or arc lamp-post fitting (Fig. 3), the brackets are so arranged that they can be adjusted to any horizontal angle. By means of the firm's patent reflector system, which this fitting also combines, the candle-power is increased in the required direction to that shown by the figures on the illustration when using 16-c.p. incandescent lamps. The lamps, which are of the ordinary type, are fixed vertically, which is the position most suited to withstand the strain of vibration. Diagrams are included in the catalogue to show that in practice the "Reason" system of reflectors and globes increases the efficiency by about 200 per cent. Thus the 16-c.p. lamps, instead of giving a mean of 32 c.p., give a maximum of 80 c.p. and a minimum of 32 c.p., or a mean of about 60 c.p. No pretence is made to compete with arc lamps, but, on the other hand, it is claimed that by the aid of these reflectors the cost of lighting with incandescent electric lamps is reduced to a minimum, enabling it to compete successfully with incandescent gas when using 80 watts per post. The Reason Manufacturing Company certainly deserve every encouragement in the efforts they are making to develop the use of electricity for street lighting, and a copy of their latest catalogue should be obtained by all who are interested in the question.

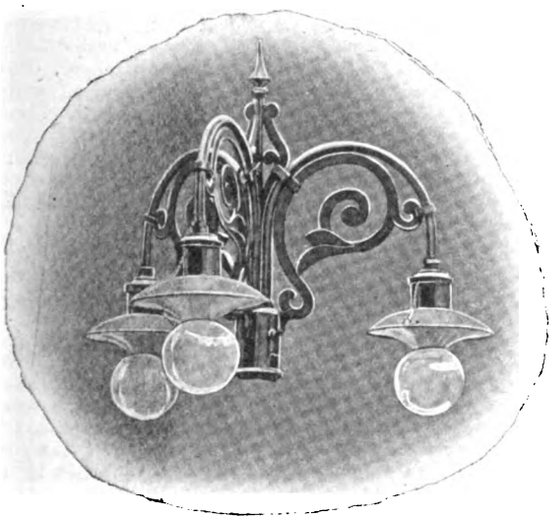

FIG. 1.—Reason Three-Way Lamp Bracket.

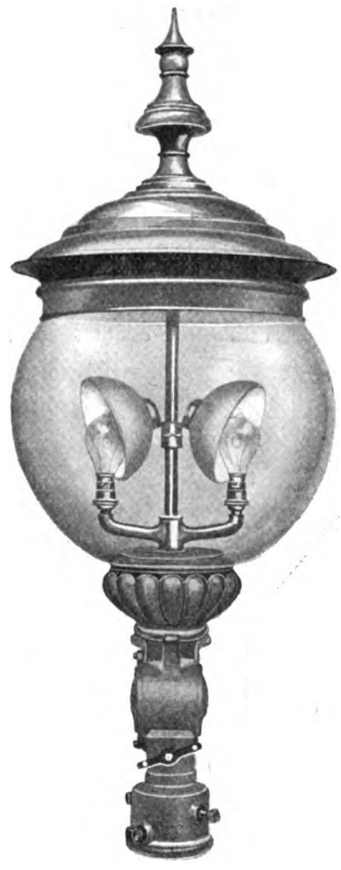

FIG. 2.—Reason Globe Type Lantern.

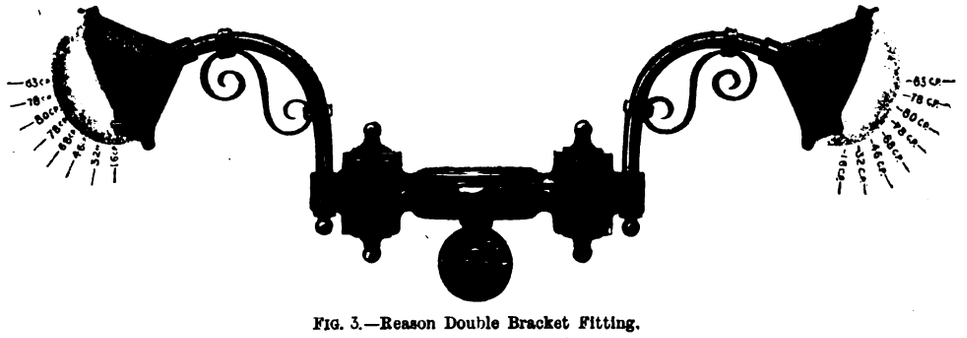

FIG. 3.—Reason Double Bracket Fitting.

New "Lundberg" Switches.

We illustrate herewith some new switches introduced by Mr. A. P. Lundberg, Pioneer Electrical Works, 477 to 487, Liverpool-road, Islington, N. The "pivot intermediate" switch (Fig. 1), Mr. Lundberg informs us, is the first switch of tumbler action, on a single base, ever produced for intermediate wiring—i.e., for controlling lamps from any desired positions in a circuit.

Digitized by Google

Previously, turn-type switches have been employed throughout the circuit, or tumbler-type switches have been used for the terminal positions and turn-type switches for the intermediate positions, so that no uniformity existed. Occasionally, when tumbler-type switches were specified for use throughout, it was necessary to couple two two-way switches together for the intermediate positions. This meant an ugly fitting being employed and more complicated circuit connections. The

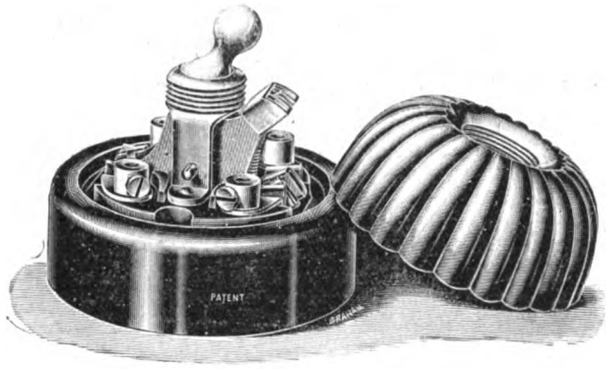

FIG. 1.

accompanying diagram of connections (Fig. 2) will show how simply the switches can be arranged. To Mr. W. H. Massey, M.I.C.E., are we indebted for the introduction in 1891 of this system, which ensures that all switches are on one pole, and consequently safe from short-circuiting faults. The method is found most useful for the lighting of corridors, staircases, or large rooms, allowing control from any door, floor, or position respectively. The "pivot intermediate," although a little higher, is of the same diameter as standard single and

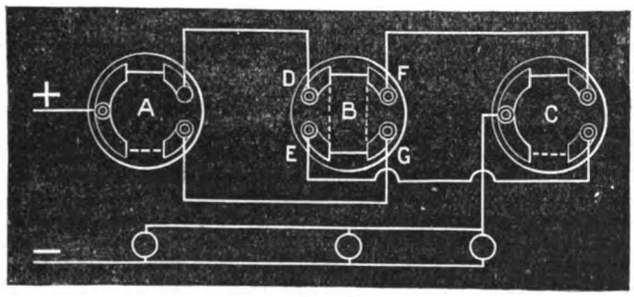

FIG 2.

two-way switches of the tumbler type, and all covers, etc., used with those switches are interchangeable with it. It has a patent variable leverage action, which is very definite. The patent *locked* type of cover can be fitted, and large size loop-in terminals are arranged, or it can be supplied for flush work, and all types of standard fronts, etc., are interchangeable. It may also be conveniently used as a reversing switch. Another application is its use as a parallel-series switch for hospital wards, nightlights in nurseries, etc., the removal of one of the copper contacts on the rocking contact arm being the only alteration necessary to convert it for this purpose. In the

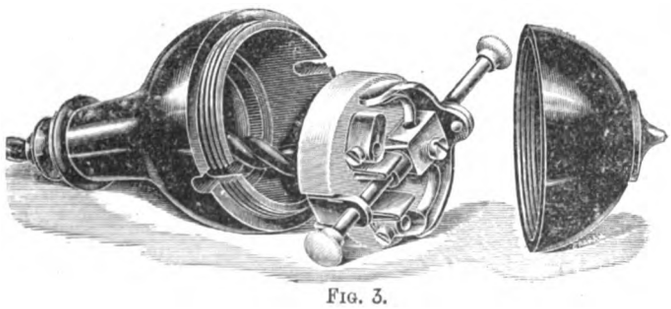

FIG. 3.

improved bowspring pear switch (Fig. 3) the current-carrying parts are mounted on a vitreous porcelain base. A wider break than in previous patterns is also arranged, in addition to improved terminals. The porcelain base is easily removable from its containing case, in order to facilitate wiring up. Samples of these switches submitted to us for inspection are of excellent finish.

Workshop Gauges.

A new catalogue recently issued by the Newall Engineering Company, Limited, Atherton's-quay, Warrington, deals with workshop gauges of the several types manufactured by the firm, who inform us they have now extended their well-known system to limit gauges, and make a number of new gauges. As an example of the latter, mention may be made of a very useful form of internal micrometer. This instrument has three measuring points, which are hardened and ground on the outside ends to a spherical form, the diameter of this sphere being somewhat below the smallest diameter the tool is intended to measure. These three measuring points are operated by means of a micrometer spindle contained in the body. The conical end of this spindle comes in contact with the inner ends of the three legs. As the spindle moves forward, so the three legs are thrust outwards until they come in contact with the sides of the hole that is to be measured. Fine springs keep the legs in contact with the conical end of the spindle. The thimble which operates the spindle is graduated to thousandths of an inch, and may be adjusted to take up wear. The legs are made interchangeable, so that one or two handles, with several sets of legs, will cover a range of sizes. The further contents of the catalogue include measuring machines, standard measuring rods, adjustable and fixed point external limit gauges, double setting and reference bars, standard snap gauges, surface plates, etc.

THE USE OF ELECTRICITY IN FACTORIES.

A circular letter has been issued to all occupiers of factories by the Home Office with regard to the use of electricity in factories, etc., accompanied by a draft of regulations which the Secretary of State proposes to make, in pursuance of Section 79 of the Factory and Workshop Act, 1901, for the use of electricity in factories and other places under that Act as follows:

FACTORY AND WORKSHOP ACT, 1901.

Draft Regulations for the Use of Electricity in Factories and other Places under the Factory and Workshop Act, 1901.

Whereas the generation, transformation, and use of electricity in electrical stations and in any factory, workshop, dock, wharf, quay, warehouse, or other place to which Section 79 of the Factory and Workshop Act, 1901, is applied by that Act has been certified in pursuance of the said Section 79 to be dangerous, I hereby in pursuance of the powers conferred upon me by that Act make the following regulations, and direct that they shall apply to all places named above, other than electrical stations, in respect of the distribution and use of electricity where the normal working pressure is greater than 250 volts and less than 650 volts between any two conductors:

1. All wires in connection with the supply shall, where practicable, be completely enclosed in strong metal casing, and where this is not practicable they shall be so arranged that there shall be no danger of any shock or of fire.

2. All main and branch circuits shall be protected by switches and by fuses or other automatic cut-outs.

3. The supply to every motor or arc lamp shall be controlled by means of an efficient switch, so placed as to be easily handled by the person in charge of the motor or arc lighting, and connected so that by its means all pressure can be cut off from the motor or arc lamp, and from any regulating switch resistance or other device in connection therewith. Provided, however, that where the arc lamps are connected in series across the outer conductors of a three-wire system and the pressure cannot exceed 250 volts from earth, it shall be sufficient if one such switch be provided for each series of arc lamps.

4. All switches and cut-outs shall be so enclosed and protected, or be in such positions or of such construction, that there shall be no danger of any shock being obtained in the ordinary handling thereof, or of any fire being caused by their normal or abnormal action.

5. All metal holders for incandescent lamps, the frames of all motors, and the metal casings of all wires, switches, fuses, and cut-outs shall be efficiently connected with earth.

6. Where the electricity is derived from a public supply, the following conditions shall be observed: (*a*) A suitable safety fuse or other automatic cut-out shall be inserted in each service line, as close as possible to the point of entry into the premises, and contained within a suitable locked or sealed receptacle of fireproof construction, except in cases where the service line is protected by fuses in a street box, but no fuse or cut-out shall be inserted in the intermediate conductor of a three-wire system. (*b*) All service lines and apparatus shall be highly insulated and thoroughly protected against injury to the insulation and against access of moisture, and any metal forming part of the electric circuit shall not, unless efficiently connected with earth, be exposed so that it can be touched. All electric conductors shall be so fixed and protected as to be free from risk of electrical discharge to any adjacent metallic substance. Provided that in regard to service lines and apparatus under the sole control of a person other than the occupier of the premises to which the supply is given, it shall be a sufficient compliance with Regulation 6 on the part of such occupier if he obtains from such person in the month of January in each year a certificate that the regulation is fully observed in regard to the said service lines and apparatus. Such certificate shall be produced at any time when required by H.M. inspectors of factories.

These regulations shall come into force on Jan. 1, 1905.

LEGAL INTELLIGENCE.

DISPUTE ABOUT AN ELECTRIC METER.

Midland Electrical Corporation v. Parsons and Sons.

This action was tried at the Wolverhampton County Court on Monday before Judge Roberts. The plaintiffs were the Midland Electrical Corporation for Power Distribution, represented by Mr. R. C. E. Plumptre (instructed by Mr. Hayward), and the defendants (for whom Mr. J. Clarke, of West Bromwich, appeared) were Messrs. David Parsons and Sons, ironfounders, The Leys, Brierley Hill.

The plaintiff company sought to recover £46. 19s. 3d. for electrical energy consumed by the defendants at their works between Sept. 28 and Dec. 31, 1903.

Mr. Plumptre, in stating the case for the plaintiff company, said the defendants were under a contract to receive electric power from his clients at the rate of 4½d. per unit. On Dec. 21 a man named Bray, in the employ of the plaintiff company, went to the defendants' works to take the reading of the meter. According to his reading the meter on that date registered a consumption of 770 units. Bray was a man of very little experience, and it was evident he had made a mistake, because on a further reading of the meter on Jan. 5 it was found to register a consumption of 1,770 units, although during the interval the works had not been in operation, and no electrical energy had passed through. There might have been a leakage owing to a defect in the installation, but the company were not responsible for that.

Counsel called several employés of the plaintiff company, who gave evidence as to the readings of the meter at different times. One of the witnesses stated that on his visit to the works he found a leakage in the installation, and he reported his discovery to a member of the defendants' firm. On March 10 last the meter was taken out and tested, and it was then found to register 2,772 units. It was also found to be 7 per cent. slow on a full load. This was rather against the plaintiff company and in favour of the defendants.

For the defence it was stated that Messrs. Parsons had not had the benefit of the number of units for which they had been charged by complainants.

The case was adjourned for independent expert evidence in regard to the meter.

TRAMCAR COLLISION.

An action arising out of a collision between a tramcar and a wherry was heard last week in the Leeds County Court, before his Honour Judge Greenhow. The plaintiff, Richard Atkinson, mineral water manufacturer, of 190, St. Ives-terrace, Armley, sued the Corporation of Leeds to recover £37 damages sustained by his wherry in the collision. The Corporation counter-claimed £4 damages done to the tramcar.

Mr. Arthur Willey appeared for the plaintiff, and Mr. Coutts Trotter, instructed by the town clerk, represented the Corporation.

The collision occurred on Feb. 27 of this year on the Stanningley-road, in a blinding snowstorm. The plaintiff's wherry was crossing the road, when it was run into by a tramcar coming from Leeds. Both the wherry and the car were damaged, and a quantity of boxes and bottles on the former were smashed, whilst the driver was seriously injured. On behalf of the Corporation, it was contended that the driver of the cart was on the wrong side of the road at the time, was driving at an excessive speed, and disregarded the warning given by the driver of the tramcar.

His Honour found for the plaintiff, holding that the wherry was run into whilst it was crossing the road, and that the driver of the tramcar did not give sufficient warning. He awarded £15 damages.

The claim of the driver of the cart for £50 damages for personal injuries was not contested by the Corporation, Mr. Trotter, on their behalf, consenting to judgment for the amount claimed, with costs.

TRAMWAY COLLISION.

At the Westminster County Court last week, before his Honour Judge Woodfall, Messrs. Wild and Robbins, market gardeners, of Sipson, Middlesex, sought to recover damages from the London United Tramways, Limited, in respect of an accident at Isleworth, whereby one of their vans was damaged.

From the plaintiffs' story it appeared that a market van drawn by a small traction engine was proceeding towards Hounslow, following another van heavily laden with manure, etc., when the driver had to pull out on to the up track to pass a steam-roller. A car approaching from Hounslow was then 30 yards away, and the car driver not making any effort to stop, collided with the van.

Wm. Connell, driver of the traction engine, gave evidence in support, and in cross-examination admitted he had had several collisions with tramcars, and that the collision was the second he had had that day.

For the defence the **Car Driver** stated that he rang his gong on seeing the manure van coming, and when he was passing the van the traction engine suddenly shot out from behind the market van on to the track. He at once applied his brake,, and was almost stopped when the collision occurred.

Cross-examined: He was quite unable to see anything behind the first market van, as it was loaded up so high. He did not consider it necessary to stop his car when approaching laden vans in case anything should drive out from behind.

His Honour, in giving judgment, said he could not see there was any negligence on the part of the car driver, and if he accepted the proposition of the plaintiffs' counsel that the car driver should have stopped when he saw the first van in case any other vehicle should come out from behind, it would be an utter impossibility to run trams at all. Judgment for the defendants, with costs.

OVERCROWDING.

A conductor of one of the West Ham Corporation electric trams was summoned for carrying 20 passengers in excess. The bulk of the passengers were going to the football match between West Ham and Tottenham Hotspur. A police-inspector said the conductor could have had 30 policemen to help to evict the excess passengers if he had wanted; while the defending solicitor pointed out that the Act under which the defendant was summoned was passed in 1842, long before electric cars were thought of. "A string of cars ought to be allowed to stand so as to take the people away," said the chairman (Mr. Berry). "I can't understand the police acting in this way. I am speaking my own mind now. The summons will be dismissed."

ACTION AGAINST LANARKSHIRE TRAMWAYS COMPANY.

In Hamilton Sheriff Court Mr. David Colville, ironmaster, of Motherwell, sued the Lanarkshire Tramways Company for £40, representing the damage done to his brougham by its being run into by one of the defenders' cars. The Sheriff found that the driver of the car was only learning his business under an experienced driver, and the accident was caused by his failure to keep a proper lookout, while no fault was proved on the part of the driver of the brougham. Judgment for pursuer for £30. 13s., with costs.

WESTINGHOUSE METER PATENT.

With regard to the report that the Westinghouse Company are commencing an action against Messrs. A. W. Tait and Arthur Whittaker, receivers and managers of Ferranti Limited, for infringement of meter patent, we are informed the firm are defending this action, also that they are giving indemnities to anybody thinking it necessary.

COMPANIES' MEETINGS AND REPORTS

EDISON AND SWAN ELECTRIC LIGHT.

The twenty-first ordinary general meeting of this Company was held at Winchester House, Mr. Henry Wolfenden presiding.

In moving the adoption of the report and accounts (of which we gave particulars last week) the **Chairman** said that the quality of the manufactures and the costs were alike favourable, and the financial position had continued to improve. They had still to contend against active competition, which they were fully prepared to meet, and the Board's confidence in the future was unabated. Their stocks had been priced in the usual conservative manner. After providing £18,760 for debenture interest, £5,000 had been appropriated to depreciation of freehold and leasehold property—a much larger sum than in previous years—and £5,000 had also been allocated to depreciation of plant, this being about 6½ per cent. of the sum at which it stood in the books. They had written off £1,000 from tool account, stocks had been written down by £1,442, and the usual £1,000 had been provided for future stock depreciation. The balance of the Altrincham debt had been reduced by £1,466. As to the auditors' reference to this debt in their report, he considered that the Board were acting in a perfectly correct manner. They had no reason to assume that the debt was not a good one. The resolution for reducing the capital of the Company was confirmed by the Court on July 26 last. The amount cancelled, however, fell short of the debit balance brought forward last year by £3,589. This amount, therefore, had to be deducted from the credit balance brought into the net revenue account, leaving £5,302 to be carried forward. The Board were advised that, whether they wished or not, this sum could not be dealt with in any other way this time, the sanction of the Court having only been given after the termination of their financial year.

The report was adopted.

UNDERGROUND ELECTRIC RAILWAYS COMPANY OF LONDON.

This Company has issued its second annual report, covering the year ending June 30 last, and we append the balance-sheet: Share capital, £2,500,000; 5 per cent. profit-sharing secured notes, £7,000,000; amounts received in respect of construction contracts, £636,276. 10s.; liabilities in respect of parliamentary deposits, £203,093. 18s. 11d.; sundry creditors, credit balances, and retentions, £576,600. 18s. 8d.—total, £10,915,971. 7s. 7d. Freehold land and buildings at Lots-road, Chelsea, including expenditure to date on construction of generating station and transmission line, £826,553. 4s. 11d.; investments in stocks and shares at cost, £2,501,124. 10s. 9d.; parliamentary deposits (£292,493. 11s. 9d. Consols) at cost, £277,256. 2s. 5d.; cost of railway construction and expenditure chargeable to various construction contracts after crediting income from investments, £6,022,313. 8s. 7d.; discount on issue of 5 per cent. profit-sharing secured notes (issued at 96), £280,000; sundry debtors, debit balances, loans, and deposits, £51,843. 4s. 1d.; cash at London and Westminster Bank, Limited, £1,556,157. 11s. 2d. (profit-sharing secured notes trustee account); cash at short call and on hand, £400,723. 5s. 8d.—total, £10,915,971. 7s. 7d.

The ordinary general meeting was held on Tuesday at Hamilton House, Mr. Charles T. Yerkes presiding.

The **Chairman** said that the power-house at Chelsea was nearly finished. The electrification of the District Railway had been kept

Digitized by Google

back somewhat by the manufacturers of materials and by the car builders, and while it was expected that electric trains would be on the railway by the first of the year, the whole of the line would not be running electrically at that time. The Baker-street and Waterloo Railway was progressing quite rapidly. The Company would be a little late there owing to the laying of the permanent way and the building of the street stations, but the delay would not amount to much. The Great Northern and Brompton and the Charing Cross, Euston, and Hampstead were going along as fast as could be expected.

Replying to a question, the **Chairman** stated that in all probability the first electric trains on the District Railway would be run from Ealing to the Mansion House.

The report was adopted.

The **Chairman** then moved a resolution to the effect that the directors be authorised to borrow a sum of money for the purposes of the Company not exceeding £850,000, and in doing so said that the present authorised amount would leave the Company a little short of the sum required, and the directors therefore asked for the authority to borrow the amount stated.

The resolution was carried.

NORWICH ELECTRIC TRAMWAYS.

The ordinary general meeting of this Company was held last week at the offices, 20, Bishopsgate-street Within, Baron E. B. d'Erlanger presiding. Particulars of the report for the year ended June 30 appeared in our issue of last week.

The **Chairman** said that satisfactory progress had been made during the year covered by the report, but the advance had not been quite so rapid as could have been desired. Taking into consideration, however, the bad state of trade throughout the country, and especially in the Eastern Counties, it was encouraging to find that the net income had exceeded that of the previous year, and was sufficient to allow the directors to recommend a dividend of 3 per cent. instead of 2½ per cent. In addition to paying the dividend, the directors proposed to place £1,200 to reserve, which would bring that fund up to £3,196. It would be the directors' policy to increase the reserve and to hold it as much as possible apart from the affairs of the Company. Of course, that object could be attained not only in buying trustee securities, but also by purchasing the Company's debentures, which yielded a better rate of interest than could be obtained on stocks specified in the Trustee Act.

The report was adopted.

ELECTROLYTIC ALKALI.

The report for the past year states that, after allowing for expenditure on maintenance of buildings, plant, and machinery, and for depreciation, the net profit amounts to £521; this, with £852 from previous year, is carried forward. The process is working well, but great depression exists in the market for bleaching powder.

NEW COMPANIES REGISTERED.

Scottish Electric Traction Company, Limited (Edinburgh).—Capital, £500. Objects: to promote, form, assist, and establish companies, syndicates, and associations for the purpose of carrying on any business or adventures of any description, whether relating to electrical enterprise or not, etc.

Amman Anthracite Collieries, Limited.—Capital, £3,000. Objects: to carry on the business of colliery proprietors, coke manufacturers, tin, terne, and black plate manufacturers, miners, smelters, engineers, electric light generators, steel converters, etc. Registered office: Brynamman, Glamorganshire.

Premier Light, Limited.—Capital, £3,000. Objects: to carry on the business of manufacturers, importers, and exporters of and wholesale and retail dealers in incandescent and other lamps, burners, mantles, and all apparatus and appliances used in connection with the employment, supply, generation, and distribution of gas and electricity, etc.

Hughes's Atlas Works, Limited.—Capital, £1,000. Objects: to adopt an agreement with the Industrial Bank, Limited, and to carry on the business of gas and electrical engineers and fitters, manufacturers of gasoliers, chandeliers, electroliers, and gas and electric fittings and appliances generally. Registered office: 9½, Union-court, Old Broad-street, E.C.

Muirhead and Co.—Capital, £50,000. Objects: to acquire the business carried on at Elmers End, Kent, under the style of Muirhead and Co., and to carry on the business of electrical, mechanical, and telegraph engineers and contractors, engine-builders, boilermakers, electricians, manufacturers of and dealers in dynamos, telegraphic instruments, wires, cables, insulators, and any apparatus and things required in connection with the generation, distribution, supply, regulation, accumulation, and employment of electricity, heat, steam, or other power.

APPOINTMENTS VACANT.

Draughtsman. See advertisement.

Improver, Mansfield. See advertisement.

Resident Agent or Manager for Singapore electric tramways.

Pupil, corporation lighting and power station. See advertisement.

Canvassing Engineer, Wolverhampton, Oct. 31. See advertisement.

Assistant Electrical Engineer, Erith Urban District Council. See advertisement.

Assistant to Canvasser, Woolwich, £2. 2s. per week, Oct. 22. See advertisement.

Engine-Driver, lighting and traction station in the Midlands, Oct. 31. See advertisement.

Assistant Electrical Engineer, Farnworth Urban District Council. Salary £120 per annum. Applications by 31st inst.

Lecturer and Demonstrator in Electrical Engineering, New Zealand Government. Salary £300; saloon passage. Oct. 29. See advertisement.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Melbourne.—The Federal Postmaster-General requires tenders for 6,000 yards of telegraph cable. Tenders by Nov. 15.

Crejour (Roumania).—The Municipality require tenders for construction and working of tramways for 50 years by Nov. 7.

Middleton.—The Corporation invite tenders for dust destructor, boilers, etc., at the electricity station. Tenders by 25th inst.

Porto Alegro (Brazil).—The term for receiving tenders for an electricity station, already announced, has been prolonged to Nov. 30.

Pretoria.—The Commanding Royal Engineer at Army Head quarters, Pretoria, is calling for tenders for the electric lighting of cantonments.

Guirgia (Roumania).—Tenders are required for the electric lighting of the town. Particulars from the town's secretary. Tenders by Jan. 28, 1905.

Ipswich.—The Corporation invite tenders for the supply of continuous-current meters for the ensuing 12 months. Tenders by 24th inst. See advertisement.

Mexico.—The Federal District Railway Company of Mexico require tenders for the electrification of six tramway lines in the town. Applications are to be made direct.

Richmond (Surrey).—The Guardians invite tenders for the installation of electric telephones at the workhouse, Grove-road. Tenders to the Guardians by 4 p.m. on 27th inst.

Pangbourne.—Tenders are required for lighting the village during the coming winter, for the Pangbourne Parish Council. Particulars may be obtained of Mr. C. West, jun., clerk.

Rugby.—The Urban District Council invite tenders for the supply of about 440 yards of ·15 three-core low-tension paper-insulated and lead-covered cable. Tenders by 25th inst. See advertisement.

Erith.—Tenders are invited for material and work in connection with the installation of electric light at the Education Committee's offices at Picardy, Belvedere. Tenders by Nov. 11. See advertisement.

Liege.—Tenders are required for the construction and working (concession) of three electric tramways. A deposit of £400 is required. Particulars from the Provincial Government, Liège. Tenders by Nov. 14.

Darlington.—The Darlington Co-operative and Industrial Society, Limited, invite tenders for installing the electric light in their offices in Priestgate, and their premises now in course of alteration in Corporation-road.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Cumberland and Westmoreland Lunatic Asylum, Carlisle.—Tenders are required for plant. Copies of tender may be inspected at the office of the Consulting Engineer, Electricity Works, Northallerton, Yorks. Tenders to the Clerk to the Committee of Visitors by Nov. 1.

Mexico.—A consular report states that there is at present a demand for the undermentioned classes of manufactures: electrical accessories for street railways, including traction, rolling-stock, rails, posts, cables, etc., electric conduits, electric motors and other accessories for motive power, irrigating machinery, steam and electric.

Rochdale.—The Tramways Committee require tenders for the wiring of car depôt. Applications, with £1. 1s. deposit, to Mr. C. C. Atchison, borough and tramways electrical engineer, Rochdale. Extra copies 5s. each. Tenders, endorsed "Car Depôt Wiring," to be addressed to the Town Clerk, Town Hall, Rochdale.

Sunderland.—The Corporation invite tenders for the supply of two 300-kw. three-phase generators, 5,500 volts, to be coupled to existing Belliss engines, and two 300-kw. synchronous three-phase motors, 5,000 volts, to be coupled to existing multipolar Silvertown dynamos. Tenders by 28th inst. See advertisement.

Liria (Spain).—The Alcalde requires tenders for the public lighting by electricity of the town, in accordance with conditions which can be seen at the office of the Secretary of the Municipality. The total amount of candle-power required will be 2,000, and the basis of the contract will be an annual payment of 6,000 pesetas (about £175).

Madrid.—An application has been received from Don José Xinxo for a concession for an electric tramway starting from the Plaza Rovira in Gracia and terminating at San Juan de Horta. The notice is published with a view to eliciting any applications for the same concession on more advantageous terms; such applications to be made by Nov. 10.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will

Digitized by Google

be supplied to applicants by the Council's agents, Messrs. John Peok and Co., 63, Leadenhall-street, London, E.C. Tenders by March 31.

Craiva (Roumania). — The *Moniteur des Intérêts Matériels* (Brussels) announces that the adjudication will take place at 4 p.m. on Oct. 25 (Nov. 7) at the Mayoralty of Craïova, of the concession for construction and working of a line of tramways (mechanical traction) in the town of Craïova. The duration of the concession is fixed at 50 years. A provisional deposit of £200 is required.

South Africa.—Orders for the supply of plant and material for the electric lighting of Vryheid will shortly be placed. Orders for 300 direct-current and 300 alternate-current meters, also for 600 fuse boxes, have just been placed by the Johannesburg Municipality. The directors of the Nourse Deep gold mine are arranging for an extension of their electrical plant.—*British South African Export Gazette.* We refer to the forthcoming contracts for Port Elizabeth (£90,000) and other South African towns in another column.

La Rochelle (France).—The Chamber of Commerce will shortly issue tenders for a crane with a lifting power for 30 tons. The beam, or the part which projects over the water or vessel alongside, should be long enough to unload from a point about 26ft. 6in. from the edge of the quay. The height of the distal end above the quay should be 15m. (49·21ft.); the vertical distance between the edge of the quay and that part of the crane directly over it, 8m. (26·4ft.). A locomobile is preferred, but should the conditions be unfavourable for installing such a machine, then a fixed crane would be adopted.

Switzerland.—The *Feuille Fédérale Suisse* of Oct. 5 contains the text of a decree of the Swiss Federal Assembly, granting a concession for the construction and working of a narrow-gauge electric railway from Sierre to Inden or Rumeling, to a syndicate formed by MM. O. Zen-Ruffinen and H. Gentinetta, of Louèche, and three other gentlemen. The capital to be raised for this purpose is fixed at 2,000,000fr. (about £80,000). The *Feuille* may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between the hours of 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

Brisbane.—Tenders are invited by the Deputy Postmaster-General for the supply and delivery at the Telegraph Office Yard, Thursday Island, of 109 tubular wrought-iron telegraph poles to Specification No. 11 and Schedule No. 51, and also for the supply and delivery at the cable tanks, Thursday Island, of three nauts of submarine cable to Commonwealth Specification No. 8 (Queensland, No. 22) and Schedule No. 50. Tenders by Dec. 12. They must state the time required for delivery; this time will be counted from the date of the notification of the acceptance of the tender. Specifications and forms of tender can be obtained at the General Post Offices, Sydney, Melbourne, Brisbane, and Adelaide. Neither the lowest nor any tender will necessarily be accepted. Tenderers are required to note that Customs' duties must be included in all charges, as per clause 2 of the general conditions. All tenders sent by post must be registered.

RESULTS OF TENDERS.

Watford.—The Urban District Council have accepted the tender of Messrs. Clifford and Gough, at £3,745, for additions to electricity works.

Foreign Contract.—Messrs. W. F. Jones and Co., of 50, Cannon-street, E.C., have secured a contract from the Brussels Corporation for 500 iron-clad three-wire house-service fuse boxes.

West Ham.—The Town Council have accepted the following tenders for material required in the electrification of the tram system in Romford-road and Leytonstone-road: 4,000 to 5,000 tons granite pitchers, Griffiths and Co.; 870 tons British steel rails, etc., P. and W. McLellan; points, etc., E. Allen and Co. (Askhams, Limited).

Johannesburg (South Africa).—The contract for lighting and tramway cables, amounting to £106,377, for the municipal scheme, has been awarded to W. T. Glover and Co., Manchester; and that for copper wire and cables, £10,789, to the British Insulated and Helsby Cables, Limited, Prescot.—*British and South African Export Gazette.*

Weymouth.—The Town Council have received the following tenders for the wiring of 12, Gloucester-row:

Ekless Bros. and A. W. Hine, Victoria-arcade (accepted)	£24	18	0
W. Gee, 28, Abbotsbury-road	33	15	0
W. Dickinson, Highfield, Bexleyheath, Kent	32	10	0
C. Jett, 7, Queen-street	30	16	0
W. D. Orchard, Market House	29	15	0
H. J. Rider and Co., 27, Chancery-lane, London, W.C.	48	0	0
R. J. Nicolson and Co., 26, Cannon-street, Manchester	48	6	6

London County Council.—The following tenders have been received for the first portion of the Greenwich generating station:

Steam, exhaust, and other piping, valves, etc.

J. Spencer, Limited, Wednesbury*	£9,785	2	0
Stirling Boiler Company, Limited, Motherwell	9,792	15	9
Mechan and Sons, Limited, Glasgow and London	9,884	5	0
S. Russell and Sons, Leicester	10,095	19	0
Foster Bros., Limited, Wednesbury	10,145	14	11
Aiton and Co., London	10,530	19	6
T. Piggott and Co., Limited, Birmingham	10,559	10	0
E. Le Bas and Co., London	10,592	15	0
Westwood and Wrights, Brierley Hill, Staffs	10,801	0	0
J. Musgrave and Sons, Limited, Bolton	11,242	7	4
T. Potter and Sons, London	11,247	2	3
Hefford and Shuttlewood, Limited, Leicester	11,513	3	6
J. G. Moore, Hartlepool	11,940	18	9
J. Fraser and Son, London	15,468	9	0

* Recommended for acceptance, with sub-contractors as follows: Holwell Iron Company, Melton Mowbray, cast-iron work; T. Piggott and Co., Birmingham, riveted pipes; Cape Asbestos Company, London, pipe covering.

Condenser and other piping, valves, etc.

J. Oakes and Co., Alfreton*	£6,418	13	1
Sir Hiram Maxim's Electrical Engineering Company, London	6,486	12	3
J. Spencer, Limited, Wednesbury	6,725	2	10
Aiton and Co., London	6,910	15	10
Holwell Iron Company, Limited, Melton Mowbray	6,974	12	5
J. Musgrave and Sons, Limited, London	7,365	0	0
E. Le Bas and Co., London	7,430	9	2
Sheepbridge Coal and Iron Company, Chesterfield	8,014	8	0
Westwood and Wrights, Brierley Hill, Staffordshire	8,473	0	0
Clayton, Goodfellow, and Co., Limited, Blackburn	11,668	0	0

* Recommended for acceptance.

Centrifugal and other pumps, motors, strainers, etc.

Electric Construction Company, Limited, Wolverhampton*	£8,083	0	0
J. Cochrane, Barrhead, Glasgow	8,500	0	0
Gwynnes, Limited, London	8,575	0	0

BUSINESS NOTES.

TRACTION.

Aberdeen.—A sum of £225,000 is to be borrowed for finishing the incomplete routes.

Bury, Rochdale, and Oldham.—The transfer of the company's undertaking was formally carried out last week.

Dover.—The Tramways Committee are to consider the question of constructing a light railway to join the tramways.

Blackpool.—Penny fares on the Promenade and Morton sections of the Corporation tramways have been decided upon by the General Purposes Committee.

Leith.—The sub-committee appointed by the Corporation to visit the tramways systems of other towns unanimously recommend the overhead principle. Preliminary arrangements are now being made for the work of conversion.

Lancashire and Yorkshire Railway.—It is reported that the company intend to erect a station in the near future between Marsh-lane and Seaforth on the electrified section of their railway.

Edinburgh.—The Lord Provost's Committee recommend that the application of the lessee company, referred to in our issue of the 7th inst., for a reduction of £50,000 in the capital sum, upon which rent is to be charged, be not entertained.

Huddersfield.—The receipts for the six months to the end of September total £37,371, and the total working expenses amount to £19,199. After allowing £12,390 for interest and redemption of debt, but making no allowance for depreciation, there is a net surplus of £5,781.

Digitized by Google

Proposed Electric Railway.—The old scheme of an electric railway between Dundee and Stanley is again attracting attention in Perthshire. It may be remembered that some time back futile attempts were made to induce one of the railway companies to undertake the scheme.

Beckenham.—The Urban District Council having received an enquiry from the British Electric Traction Company as to whether the Council would be able to supply energy for the working of the Penge tramways, and upon what terms, the Council desire the company to state when they are likely to require the current.

Keighley.—The tramways were opened last week. Major Pringle, R.E., who inspected the system on behalf of the Board of Trade, expressed his entire satisfaction with it. The service was promptly opened to the public, and is being well patronised.

Yarmouth.—The Council have confirmed the recommendation of the Tramways Committee that notice be served upon the Gorleston Tramways Company requiring them to sell, and a committee has been appointed to negotiate with the company. The Board of Trade have approved the extension from St. Peter's-road to Queen's-road.

Perth.—The Council have ultimately arrived at a decision in regard to the tramways, which are to be electrified. Mr. Lambert, the electrical engineer, states that a more powerful engine will be introduced at the generating station, and that the Corporation will be able to provide power for the tramways under highly economical conditions.

Derby.—We are pleased to learn that the question of delay in the execution of works between the Corporation and Messrs. J. G. White and Co., Limited, has been amicably settled. It is understood that the work actually carried out was largely in excess of the contract requirements and involved numerous changes in the specifications. This naturally caused the time for completion originally specified to be exceeded.

Halifax.—The new double line of tramway connecting Bailiffe Bridge and Brighouse has been opened. When the proposed Bradford extension from Wyke to Bailiffe Bridge is carried out—as is hoped to be done before 12 months have passed—it will be possible to travel from Bradford to Brighouse, a distance of seven miles, entirely by electric tramcar, at a cost of 4d. The Lancashire and Yorkshire Railway have forwarded to the Sowerby District Council a protest against the suggestion that, in consideration of the Corporation extending the tramways to Sowerby, that authority should remit the district rate on such property for five years.

Leeds.—The accounts for the half-year from March 26 to Sept. 29 show receipts totalling £161,089. 5s. 10d., as against £151,367. 15s. for the corresponding six months last year, an increase of £9,721. 10s. 10d. The advance is attributed to better weather and the introduction of the split-turn system of working. There was an increase in the working expenses of £2,865, the total being £83,500, as against £80,635. The estimated gross profit was £77,585, and after the deduction of charges for depreciation, interest, and sinking fund, it is expected there will be a net profit of £39,293. 15s. 5d. This is an increase of £2,403. 9s. 5d. over the net profit in the corresponding half-year.

Bury.—A deputation from the Ramsbottom District Council attended upon the Tramways Committee last week with a view to the extension of the Tottington section. The matter is receiving the attention of the committee. The Bolton Corporation have intimated their consent to the Bury Corporation obtaining powers to lay tramways to the borough boundary at Ainsworth. As a consequence of this the Bolton Corporation have rescinded a resolution arrived at by them some time ago to themselves apply for powers to extend their Bury-road tramways. Another conference has been held in reference to the Heywood tramways, and although a final decision has yet to be arrived at, it is understood that further progress with the negotiations was made.

Heywood.—At the meeting of the Town Council, a desultory discussion ensued as to the negotiations with Bury and Rochdale. The Chairman of the Electricity and Tramways Committee, replying to the criticisms that had appeared in the local Press to the effect that the dust destructor ought to be used for driving the tramways, stated that the refuse at Heywood was much inferior to that at some of the towns where the destructor was employed for this purpose, so that he did not think there would be any advantage in connecting the destructor with the electrical works. He mentioned that the borough electrical engineer had told him there were times when the heat generated by the destructor was so low that it would not work even a small mortar mill. The borough and electrical engineers have prepared a report on the matter, which agrees with the views expressed by the chairman.

Bournemouth.—The arbitration proceedings to determine the costs to be paid by the Corporation for the undertaking of the Poole and District Electric Traction Company were resumed last week. The amount claimed by the company is £420,589, and the following are the valuations of the experts. For the company: Mr. Sellon, £420,589; Mr. More, £458,525; Mr. Hammond, £483,778; Mr. Dickenson, £59,237; and Mr. Conachy, £377,732. For the Corporation: Mr. Waller, £70,400; Mr. E. M. Lacey, £66,174; Mr. F. W. Lacey, £55,379; and Mr. Baker, £58,947. Mr. J. B. Hamilton, tramway manager at Leeds, who was called on behalf of the Corporation, estimated the value at £70,659. The evidence on both sides having been concluded, Mr. Lloyd, K.C., addressed the arbitrators on behalf of the Corporation, and characterised the company's claim as "a grossly exaggerated and extravagant" one.

Leamington.—At the meeting of the Town Council the Tramways Committee reported that they had received a letter from the engineer of the British Electric Traction Company enclosing a set of plans in duplicate showing a single line of tramway, with occasional passing places, throughout the borough, proposed to be laid by the tramway company, and stating that such plans cancel those showing a double line submitted on Aug. 5, 1903. The committee recommended that such plans be disapproved for the following (amongst other) reasons: (1) that 4in. by 5in. sett paving was shown in certain streets, whereas the tramway company had agreed to lay wood paving throughout the borough; (2) that the type of pole approved by the Council for use in Victoria-terrace and The Parade could not be used if a single track were laid; and (3) that for an efficient electric tram service the proposed single track would be unsuitable. The report was adopted.

Croydon.—The Corporation have decided to include the following further extensions of the tramway system in their Bill: (*a*) an extension of the tramways system from Lower Addiscombe-road along Morland-road, Woodside, and Portland-road to near Norwood Junction Station. (*b*) An extension from Thornton Heath terminus to the Gloucester public-house, Whitehorse-road (agreed to by the Council on Oct. 27, 1902. This to be a single line with turn-outs. (*c*) An extension from High-street, South Norwood, along South Norwood-hill to its junction with Church-road. This to be a single line with turn-outs. The following provisions are also to be inserted: (*a*) borrowing powers for extending the Thornton Heath and Purley depôts, and for the provision of new cars; (*b*) power to run omnibuses. The Corporation have decided to oppose the application of the British Electric Traction Company for an extension of three years in which to complete the Mitcham Light Railway. A depôt is to be constructed in Morland-road.

Bradford.—The question of the trams passing under the railway bridge at Eccleshill was discussed at Monday's meeting of the Tramways Committee. The Board of Trade inspector objected to the limited distance between the upper deck of the cars and the bridge. It appears, however, that the Corporation have a number of cars, including those taken over from the Mid-Yorks Tramways Company, which allow of the necessary clearance, so these will be utilised for the Greengates route. At a meeting of the Tramways Committee on Monday a report on the year's working was adopted. We have already published particulars of the accounts. Reference is made to some minor extensions which have been made, and it is considered that practically every part of the city is well served, so far as tramways are concerned. In pursuance of the policy of undertaking the electrical equipment of sections without the aid of contractors, the committee are pleased to state that this work has again been executed by the department with very satisfactory results. The route length of the tramways worked by the Corporation now totals 53 miles. Roughly speaking, the committee maintain two-thirds of the surface of these streets with granite paving.

Belfast.—At Monday's meeting of the Tramways Committee it was reported that the London County Council had granted permission to Mr. A. Young to act as valuer, on the understanding that the Belfast Corporation would take up the minimum amount of his time and that he should receive no fee. The advisability of having the overhead telephone wires removed so that they might not interfere with the electric traction wires was discussed, and it was decided to give notice to the National Telephone Company in the terms of their agreement with the Corporation, this notice to expire in May next. It was also decided that an endeavour should be made to effect an arrangement on similar lines with the postal authorities. The tramways manager (Mr. A. Nance) intimated that he would require the assistance of an architect in making the necessary alterations at the car depôts, but he believed this work could be done for a less sum than had been anticipated. Alderman Wm. M'Cormick moved, and Councillor Thompson seconded, that Messrs. Graeme Watt and Tulloch should be appointed architects for this and other work. It was resolved that the work in connection with the tramway depôts should be carried out by the Corporation's own staff. A letter was received from the Belfast and County Down Railway Company, stating that their engineer was prepared to consult with the city surveyor in regard to the proposed raising of the bridge at Bridge End. It was agreed that Mr. Nance's office should be connected with the telephone exchange.

Cardiff.—The annual report of the tramways manager (Mr. Arthur Ellis) was before the committee last week. This shows that the total income from all sources amounted to £108 442. The working expenses totalled £68,474. 4s. 2d., leaving a gross profit on the undertaking of £39 964. 7s. 11d. The surplus income was dealt with as follows: interest on loans and repayment of principal, £33,601. 9s. 5d.; estimated profit allocated to relief of rates, £642; payment out of revenue for construction of Fair Oak-road loop, £403. 0s. 4d.; leaving a surplus balance for disposal amounting to £5,317. 18s. 2d. The expenditure on claims account amounted to £1,185. 10s. 3d., leaving a surplus of £1,361. 6s. 11d., which, added to the total amount brought forward last year, made a total insurance fund of £2,950. 10s. 9d. The actual net surplus balance for the year was really £7,724. 5s. 5d., and he recommended that £9,137. 0s. 4d. should go towards the creation of a reserve fund to meet the heavy payments that would come upon the department in future for the maintenance and renewals, particularly of the permanent way. Considerable discussion took place on this recommendation, Mr. Ellis pointing out that all repairs and renewals to the overhead wires and cars, etc., were paid for out of revenue, and there was practically no depreciation in those respects, but some years hence the permanent way would have to be renewed, and it was advisable to have a reserve fund for this purpose. Some of the members could not quite see how there could be no depreciation in the cars, overhead wires, etc., and Mr. Ellis explained that so far as the overhead equipment was concerned, as soon as a piece of wire was worn it was replaced by a new piece, and in the course of time all overhead wires would be renewed in that way out of revenue. In the same way the cars were renewed as each portion of them became worn out. Councillor Crossman thought Mr. Ellis's remarks constituted a strong argument in favour of the establishment of a works department. Mr. Ellis pointed out that the loan charges were increasing, and the revenue

Digitized by Google

was stationary as they were carrying as many passengers as they could expect to do, the whole of the population of Cardiff being carried in the cars nearly three times a week. The time had come, therefore, to consider the question of raising the fares on some of the routes. This matter, however, is to be considered at a special meeting to be held in November. Mr. Ellis's recommendation in regard to the creation of a reserve fund was adopted.

London County Council.—The Council have arranged with Messrs. J. G. White and Co., Limited, for a reduction by £1,569 of the contract price of £95,000 for the reconstruction of the Kennington-Streatham section, as after the contract had been prepared it was decided to suspend the tram traffic, thus saving the contractors from providing a temporary track. The Highways Committee of the Stoke Newington Borough Council recommend that the Council assent to the overhead system for the tramways on the Moorgate-street to Manor House route, having regard to the material difficulties and expense in connection with the conduit system. The same committee further reported that, pursuant to reference, they had reconsidered their recommendation with respect to the application of the County Council to the Board of Trade to sanction the use of a centre conduit slot, 1in. in width, in lieu of a slot ⅜in. in width on certain of the County Council tramways, including those in the Stoke Newington-road, High-street, and Stamford-hill. The committee instructed the borough surveyor to inspect the Bournemouth tramways constructed on the side or rail slot principle, and having heard his report, directed a communication to be addressed to the Board of Trade to the following effect: "That the Council was unable to approve of the proposal of the London County Council for a 1in. slot in the centre of the track in lieu of the ⅜in. slot previously proposed, and was, moreover, of opinion that it was desirable that one of the rails should be adapted for a slot for the plough in lieu of putting the same in the centre of the track as suggested. This system had been successfully worked in other places, and it must be apparent that the fewer rails there were in the road the less the public disadvantage. That the Council also desired to draw attention to the undesirability of putting the covers of the insulator boxes level with the surface of the road. It was proposed to place four of these covers across the track at every 15ft., but by placing the same under the paving a better surface to the road could be maintained. The Council have rejected as grandmotherly legislation a proposal that all cars, buses, etc., plying for hire should be compelled to exhibit a list of fares outside the vehicle; and on the ground that they had already made sufficient concessions, the Council also rejected the following proposition: "That it be referred to the Highways Committee to consider and report upon the practicability of granting to clerks and all women workers using the Council's tramcars before 9 a.m. the privilege of travelling at the reduced fare now enjoyed by all working-men up to 8 a.m."

LIGHTING AND GENERAL.

Bishop Stortford.—Application is to be made for an electric lighting provisional order.

Dudley.—The profit on the municipal electrical undertaking for the past year amounts to £650.

Bermondsey.—The treasurer's accounts of the electric undertaking shows a credit balance of £512.

Hornsey.—The Borough Council have decided to supply current to depôts and schools at a uniform charge of 4d. per unit.

Removal.—Mr. A. S. E. Ackermann, A.C.G.I., A.M.I.C.E., has moved into larger offices at 25, Victoria-street, Westminster.

Croydon.—An extension of mains in Melfort-road, suggested by the borough electrical engineer, is to be carried out at a cost of £560.

Leek.—The Urban District Council are raising £600 as part of a loan of £1,800 sanctioned in respect of the electricity department.

Wolverhampton.—The Town Council have approved extensions of lighting mains at an estimated cost of £220 and £645 respectively.

Leeds.—The Lighting Committee have decided to recommend the Council to extend the supply of current for lighting purposes to Kirkstall.

Whitby.—The Urban District Council proposes to promote a Bill which includes power to wire private premises for electric light and to let out electric apparatus.

Greenock.—The units of electricity generated during the month of September amounted to 139,856, as compared with 113,272 in the corresponding month of last year.

Cheshunt.—Consequent upon an enquiry by the Board of Trade, the Council have decided to inform that authority of the steps they are taking to carry out their electricity supply order.

Stamford.—A committee has been appointed to report upon the cost of electric lighting and heating at the union house. It is stated that at present the cost at the house is about 2d. per unit.

Sale of Plant.—Particulars of various sales of plant, including an electric lighting plant suitable for country residence, a 50-b.h.p. Tangye gas-engine, and 1-h.p. motor, appear in another column.

Ipswich.—The Council have entered into an agreement with the General Electric Company, Limited, to supply motor installations for use within the borough upon terms for a period of seven years from the 19th inst.

Margam.—The District Council on Monday, after discussing the draft agreement with the South Wales Electrical Power Company, resolved to eliminate clause 11 giving the company power to provide energy for collieries and works.

London County Council.—On Tuesday it was reported that the period for the repayment of the loan of £1,415,000 to St. Marylebone has been fixed at 38 years. The tramway offices of Camberwell are to be wired and fitted at a cost of £350.

Wireless Station.—The wireless telegraphy station at Ushant is now open for business, the charge being 7½d. per word in addition to the ordinary telegraphic rate. All telegrams must bear after the address the word "Radiotelegramme."

South London Electric Supply Corporation.—The company reports having sold during the first nine months of the current year 6,590,572 units, as against 2,788,400 units for the corresponding period of last year, showing a gross revenue of £51,009 as against £27,065.

Pembroke.—The new electric generating station at the dockyard is approaching completion. The present contract is for five miles of trenches, and in each trench two, three, or more ducts are laid. Each contains three cables, giving a total of 40 or 50 miles of electric cable.

Stratford.—The Town Council have resolved to enter into negotiations with the Birmingham Installation Company with a view to an arrangement with them, subject to the sanction of the Board of Trade, to transfer to them upon terms to be agreed upon the Council's powers under the electric lighting provisional order.

Dunfermline.—The Town Council have decided to engage Mr. William Brooks Sayers, M.I.E.E., Glasgow, to furnish an independent report as to the Council's position with regard to electric supply, and the best course to pursue, whether under agreement with the Fife Electric Power Company or independently of that company.

Holyhead.—The Urban District Council have referred back to committee a recommendation that £60 be expended on the electric works house to place it in a fit condition as residence for the electric engineer. The work of connecting Holyhead with the telephonic trunk is to be proceeded with at once, private persons having become guarantors for £101. 15s.

Marconi Wireless Telegraphy.—A contract has been awarded for the dismantling of the present Marconi wireless telegraphy station at Table Head, Cape Breton, and for the removal of the towers four miles inland. The construction work will be completed by Jan. 1 next. The station will be the most powerful yet erected by the Marconi Company.

Stock Exchange.—The Stock Exchange Committee have ordered Metropolitan Railway £3,611,558 3½ per cent. preference stock, £1,110,715 3½ per cent. "A" preference stock, £3,601,278 3½ per cent. debenture stock, and £335,214 3½ per cent. "A" debenture stock, in lieu of the preference and debenture stocks now quoted to be quoted in the official list.

Montrose.—At the last Town Council meeting a motion for the appointment of a committee to reconsider how the Corporation might acquire the whole of the electric lighting plant in the burgh found no seconder. It was contended that the negotiations would take some time, and it was in the ratepayers' interest to purchase the plant. The company had made £11,000 of profit.

Caversham.—The Urban District Council last week decided in favour of taking steps to obtain a provisional order authorising the Council to supply electricity for any public or private purposes within the district. No actual move has yet been made, because the attendance at the meeting was so small that the members would not take the responsibility of incurring the expense.

Eastern Telegraph Co.—After payment of interest on the debenture stock, dividend on the preference stock, and the interim dividend of £1. 5s. per cent. on the ordinary stock, there remains a balance available sufficient to pay a final dividend of £1. 5s. per cent. and a bonus of £2 per cent. (both tax free) on the ordinary stock, making a total distribution of 7 per cent. for the year ended March 31.

Willans and Robinson, Limited.—According to a statement by Mr. Mark Robinson at the recent general meeting, the above firm proposes to take up the manufacture on a large scale of the Diesel engine. We are informed that this move is being made under a manufacturing arrangement with the Diesel Engine Company, Limited, of London, with whom the selling rights remain and who will deal with all enquiries.

Geltsdale.—The Postmaster-General's offer to provide and maintain a double-wire circuit fitted with four telephones between the waterworks engineer's office, Fisher-street, Carlisle, and the attendants' cottages at Cumwhintom, Castlecarrock, and Binney Bank, for an annual rental payable in advance of £141 under an agreement for 10 years, has been accepted. Messrs. Mansergh are to have the work between Carlisle and Castlecarrock put in hand at once.

Callender's Cable and Construction Co.—The directors have decided to pay an interim dividend of 5s. per share, being at the rate of 10 per cent. per annum, on the ordinary shares of this company. The ordinary share register will be closed from the 20th to 31st inst., both days inclusive, for the purpose of preparation of such dividend, and the warrants will be payable on Nov. 1. Sir J. Fortescue Flannery, M.P., has been elected a director in place of Lieut.-Colonel G. A. Elliot, deceased.

Islington.—At to-night meeting it will be proposed (1) that the salary of Mr. Percy E. Rycroft, the assistant engineer and works manager at the electric lighting station, be increased to £250 per annum as from the 25th inst.; (2) that increased siding accommodation be obtained at the electric lighting station from the Great Northern Railway Company, the company having intimated that for an annual payment of £5 they will construct an additional siding; (3) that £368 be expended upon extension of mains.

Woolwich.—We understand that at a meeting of the Woolwich Non Political Ratepayers' Association last week the following resolution was carried: "That in the opinion of this association the immediate extension of the electric lighting and power works at Shooter's Hill, Eltham, and Lee Green is desirable both from a business and economic point of view, and this association trusts that the Borough Council will decide to adopt the scheme submitted by the Electricity Committee on Sept. 29, with a view of carrying on the same."

Digitized by Google

Perth.—The electric light has been introduced into St. Paul's Established Church. There are 113 16-c.p. lamps, the gallery being lighted by electric standards, and the body of the church by electroliers. Messrs. M'Leish, Morrison, and Co., Mill-street, Perth, were the contractors. The work was carried out according to specifications drawn up by Mr. Lambert, the electrical engineer, while the fittings have been supplied by the Ediswan Company.

Huddersfield.—The borough electrical engineer's last report shows that at the beginning of October there was a total of consumers amounting to 1,974, as against 1,954 in September, an increase of 20, whilst there were 135,468 lamps connected, being an increase of 1,255 over the number in September. The total length of mains on Oct. 1 was: primary, 88,485 yards; secondary, 63,864 yards. In connection with the proposed supply to Golcar, it has been decided to apply for sanction to borrow £4,300. Mr. A. V. Anderson has been appointed junior assistant at a salary of £78 per annum.

Oriental Telephone and Electric Co.—The directors have declared the following dividends: (1) an interim dividend of 3 per cent. on the 6 per cent cumulative preference shares for the current year (less income tax) payable to those shareholders whose names are on the share registers of the company at this date; (2) an interim dividend of 3 per cent. on the ordinary shares for the current year (free of income tax) payable to those shareholders whose names are on the share registers of the company at this date. The warrants in both cases will be posted on 31st inst. The share transfer books are closed until 31st inst., inclusive.

Electric Lighting Shares.—With the coming of the dark winter days and the consequent calling of the public's attention to electric lighting companies, the usual improvement in this class of investment may be regarded as probable. Moreover, the best class shares in this section return a 4½ to 5 percentage to their proprietors, and the management of electric lighting concerns has now reached such a pitch of excellence in so many instances that investors can confide their money safely to the shares. If the market is not particularly free, it is a very steady one, and dealings are at all times easy in a reasonable amount of shares.—*Westminster Gazette.*

Hydro-Electric Plant.—Don José Luis Gomez Navarro is to appropriate 10 cubic metres per second of water from the River Segura at the point called Rio Muerto, for the production of electric power, to be used for industrial purposes in Murcia and other towns. The *Gacetas* containing the foregoing notice may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between the hours of 10 a.m. and 5 p.m. (Saturdays 10 a.m. to 1 p.m.). Snr. Andres Lifebore has obtained from the Mexican Government permission to utilise the water of the Amacuzas, in the Tetecala district, State of Morelos. The maximum to be taken is 80 cubic metres per second.

Dartmouth.—At the end of 1903 the Urban Electric Supply Company, Limited, had connected to their mains 225 consumers with a total of 6,610 8-c.p. lamps. The corresponding figures on Sept. 30, 1904, were 366 and 9,473. The average of 318 8-c.p. lamps per month is 50 per cent. above the estimated number at the beginning of the year, while there are still 20 consumers waiting to be connected, equalling some 760 8-c.p. lamps, which will make over 10,000 at the end of the year. The works last year generated 112,192 units, out of which 73,650 were sold. This year up to Sept. 30 they have generated 109,470 units and sold 77,187. There being still three months to complete the year's working, it is hoped that over 150,000 units will have passed out of the dynamos.

Walsall.—The Electricity Committee in their last report give the total number of consumers supplied on Sept. 30 as 366. During the past month the total units generated at the station was 123,753. The total output from the main generators was 119,857 units. The total units from the transformers was 93,617 (estimated). The total units registered on the meters was 88,416. The machinery was run for 685 hours. The wages paid amounted to £123. An offer of the Reason Manufacturing Company, Limited, has been accepted, who will take back the old demand indicators, which, owing to the change in the method of charging consumers, will not now be required, and allow a credit of 10s. on the large size and 7s. 6d. on the small size, on the condition that the committee purchase some of their ordinary meters at 47s.

Tonbridge.—At the last meeting of the ratepayers' association Admiral Pattisson said he hoped the electric light was making a move in the right direction, and he thought they should do all they could to support the Council in carrying out that undertaking. He had seen that several members of the Council had run down certain lights and the undertaking generally. It was a mistake. It was their duty to support it all they could—the school had done so and they ought to do so. It would pay sooner or later, and it ought to have their help. Several members spoke in a similar strain, and a written question put by another member was read as follows: "Is it good form for some members of the District Council to continue to deprecate and hamper the progress of the electric light now that it is the property of the ratepayers?"

Salford.—The abstract of last year's accounts of the Electricity Committee show receipts for current, rent of meters, etc., of £67,287, out of a total revenue of £68,767. The expenditure amounted to £25,907, leaving a balance to credit of profit and loss amounting to £42,860. The generation of electricity cost £15,141. After liquidating a deficiency of £2,394 on last year's account, and paying £31,086 in interest and redemption of loans, etc., the committee placed £8,000 of the gross profit to credit of a depreciation and renewals fund, and the balance—£1,380—was transferred to the district fund in relief of the rates. The expenditure on capital account to March 31 last was £48,233, and the income £42,627, showing a debit balance of £5,606. The total liabilities amount to £521,537, and the assets to £563,693, showing a balance of assets over liabilities amounting to £42,155.

Hammersmith.—Application is to be made to the London County Council for a loan of £18,482 for electrical machinery. The probable expenditure of the additional plant which the Council has recently agreed to provide comprises the following items: Three boilers (including brickwork, feed-water heater, forced-draught apparatus, economiser, pumps, piping, etc.)—total estimated expenditure for completed extensions, £12,100; total amount of contracts accepted to date, £4 899; estimated value of contracts yet to be settled, £7,201; estimated payments on account of extensions to March 31, 1905, £3,600. Two 1,500-kw. turbo-alternators (including condensers, etc.)—£20,000 (£18,482; £1,517; £10,500). Ash conveyor, tank, battery, chimney, flues, extension of condensing main, buildings, etc.—£5,900 (£2,067; £3 832; £2,054). Clerk of works and sundries—£2,000 (—; £2,000; £500). Feed pump, superheater, etc., already installed (transferred to capital account from last year's revenue account)—(£1,828). Totals—£40,000 (£25,449; £14,551; £18,482).

King's Lynn.—The electrical engineer in his last report stated that since the last meeting applications had been received for a supply to 339 additional lamps of 8 c p. or equivalent, making a total of 19,686, and that there were now 480 connections to private consumers, being an increase of four. The following statement was submitted: Units generated—July, 1904, 25,436 (1903, 18,149); total units sold to private consumers (light and power), 21,484 (8,638); units sold at power rates, 15,643 (4,919); cost of fuel, stores, repairs, and wages at station, £116. 18s. 10d. (£100. 19s. 11d.); cost per unit generated, 1·1034d. (1·3355d.); wages of lamplighters and outside staff, £18. 16s. 9d. (£19. 15s. 5d.). Units generated, August, 1904, 29,974 (1903, 22,977); total units sold to private consumers (light and power), 15,998 (11,663); units sold at power rates, 9,729 (4,793); cost of fuel, stores, repairs, and wages at station, £120. 0s. 10d. (£93. 11s. 1d.); cost per unit generated, 0·9611d. (0·9771d.); wages of lamplighters and outside staff, £21. 3s. 5d. (£17. 16s. 5d.).

Liverpool.—On Wednesday the Electric Power and Lighting Committee passed a vote of thanks to Mr. Richard Dart for his services as chairman during the past municipal year. Mr. Dart, in responding, said, according to the *Liverpool Courier*, that the number of consumers of electricity in the city had increased from 4,790 to 5,345. The total amount of energy supplied for lighting and power showed an increase of 20 per cent. over last year, and 12½ per cent. increase on the electrical energy supplied for tramways, the increase on the total output being 15 per cent. The new power station at Lister-drive would commence work in the course of a few weeks, and additional plant was being provided for sub-stations. Consequent upon active building operations five miles of new streets had been lighted, and the work of lighting passages, commenced in 1896, had now been completed, 2,664 lamps having been fixed at a first cost of £1,300. The annual additional charge would be £4,500; 5,435 gas-meters had been tested, and 578 rejected; 2,936 electricity meters tested, and 1,079 rejected. The average illuminating power of the gas had been 20·83 candles, the parliamentary power being 20 candles. The city was at present lighted by 18,312 lamps—electric and gas.

Bedford.—An enquiry has been held into the Town Council's application for sanction to borrow £44,950 for purposes of electric lighting. Mr. Hedley Baxter, the town clerk, said the estimated population of the borough was 37,100, the last census showing a population of 35,144. The rateable value was £197,614, and the loans on the district fund £19,006. He understood there was to be no opposition to this application. In 1898 an application was made to the Local Government Board for sanction to a loan of £41,000, which was granted. At that time the number of consumers connected with the mains was 376, and the number on March 31 this year was 1,140, or an increase in six years of 773. The number of inhabited houses in the borough was 7,350. During the last two years there had been a profit on the electric works undertaking for the first time; they had now turned the corner. The profit for the year ending March 31, 1903, was £23. 11s. 8d., and for the year ending March 31, 1904, the profit was £744. 11s. 6d. The electrical engineer (Mr. W. R. Phillips) gave details of the proposed expenditure. He also stated that everybody had under-estimated the demand. It had been contemplated that there would be 150 increase in the consumers; but they had spent £7,730 on house connections alone, instead of £1,500.

Electrical Mining Plant.—Messrs. Scott and Mountain, Limited, of the Close Works, Newcastle-on-Tyne, have just secured a contract from the Alquife Mines and Railway Company for a complete electrical plant for their mines in the South of Spain, which installation is of considerable interest on account of water power being used. The Alquife Mining Company have secured the water rights of the Rio Alcazer, and from this river they are able to get, under the worst conditions, from 3,000 h.p. to 4,000 h.p. with a fall of 280ft. The electrical plant consists of a 300-h.p. double Pelton wheel, with a special form of governor, the turbine being fitted with a heavy flywheel and directly coupled to one of Messrs. Scott and Mountain's three-phase alternating-current generators of 250 kw. capacity. This generator delivers three-phase current at an E.M.F. of 500 volts to a transformer, where it is transformed to 5,500 volts, and conveyed from the power station to the mine, a distance of nearly 10,000 yards, by bare overhead wires. At the mine the current is again transformed down to 500 volts by means of step-down transformers for the power motors, and to 250 volts for the lighting of the private houses, workshops, and offices. At the mine there will be installed two motors of 100 h.p. each for driving the briquetting machinery, and six 15-h.p. motors for driving the elevators, etc.; also nine 5-h.p. motors for driving the feeding gear from the kilns, hoists, workshops, etc. About 275 incandescent lamps will also be installed throughout the workshops, offices, etc.

London Gazette.—The partnership between George Becker and Otto Böhndel, carrying on business as agents for electrical fittings at 29, Cock-lane, Snow-hill, London, under the style of Schoen Bros., has

Digitized by Google

been dissolved by mutual consent. The partnership between George Arthur Smith and George Herbert Huntsworth, carrying on business as electrical engineers at 180, Regent-road, Liverpool, under the style of Smith and Huntsworth, has been dissolved by mutual consent. The partnership which has for some time past been carried on by Albert Clulee Hands and George Hands under the firm of Hands Bros., at 30 and 34, Snow-hill, London, in the trade of electrical engineers, manufacturers of electrical fittings, etc., has been dissolved by mutual consent. A general meeting of the London Telegraph and Steam-Gauge Electric Company, Limited, will be held at 4, Romford-road, Stratford, Essex, on Nov. 21, 1904, at 4 p.m., for the purpose of having an account laid before them, showing the manner in which the winding-up has been conducted and the property of the company disposed of. The creditors of the Bath Electric Manufacturing Company, Limited, are required to send their names and addresses and particulars of their debts or claims to Mr. Augustus C. Comley, Albion-chambers, Bristol, liquidator. The Electrical Bleaching Company, Limited, has been wound up voluntarily, and Mr. William Barrett Winnicott. Queen-street, Nottingham, accountant, appointed liquidator. The first meeting in the estate of James Marsden, 39 and 40, Woodcock-street, Birmingham, electric fittings manufacturer, will be held on Oct. 26, at 11 a.m., at 174, Corporation-street, Birmingham. The last day for receiving proofs in the estate of Thomas Hyom, electric light fitter, etc., 139, Fawcett-road, Southsea, is Nov. 1, 1904.

Lichfield.—At the last City Council meeting a report was adopted giving the history of the Council's electric lighting order. In this report the Electric Lighting Committee said they had had before them several proposals for working the electric lighting order which the Council obtained in 1901. At first it had been considered that the best course to be adopted would be by arrangement with a company or firm whereby the Corporation should borrow to the extent of £10,000 to put down an electric lighting station with mains thereto, and then lease the undertaking to a company or firm for a term of years, upon conditions which should include under an ample guarantee and satisfactory security a provision that such company or firm should repay the principal and interest, including all sinking fund charges during the term, thereby preventing any burden on the rates, and at the end of such term the whole of the undertaking and works should become the property of the Corporation. The parliamentary agents, however, advised that in their opinion the Board of Trade would not consent to such a proposal, as they would regard it as being practically a transfer of the order, and that the only way to carry such an agreement into effect would be for the Corporation to apply at once for a further order extending the time for carrying out the original order and providing for its transfer to a company or firm which would have to be specifically named in the further order. The committee consequently resolved not to apply for the further order, but to await the future development of the matter, seeing that two notices had been served upon the Corporation by firms intimating their intention to apply for electric lighting powers in the city. Mr. Geo. Ashmall has been appointed the secretary to the Electric Lighting Committee at the annual salary of £25, exclusive of parliamentary, litigious, conveyancing, and other legal work, and out-of-pocket payments.

Dublin.—The adjourned enquiry was held on Tuesday into the applications made by the Corporation for sanction to borrow £21,000 in connection with the scheme for lighting the city by means of electricity. Mr. Ignatius O'Brien, K.C., and Mr. Philip White, who appeared in support of the application, said, as reported in the *Dublin Mail*, that the necessity for the loan arose from the absolutely unexpected success of the electric lighting scheme. The existing electric light plant at the Pigeon House consisted of a generating plant of four separate units. These units consisted of plant capable of producing two lots of 500 kw. and two of 1,000 kw.—a total of 3,000 kw. The estimate was 1,000 kw., but the works were so constructed that they could be increased fives upon demand. Mr. Hammond estimated that something more than 2,000 kw. could be safely produced without risk out of the existing works, but the margin which he estimated for was only 200 kw., or 10 per cent. The existing boilers were capable of producing 2,500 kw., placing no undue stress on the installation. That was a material figure. The capacity of the cables was 2,800 kw. But the demand had entirely exceeded the most sanguine hopes of the original projectors of the scheme, and as they were under obligation to supply electric light to every person occupying premises within the area in a street where a circuit ran who demanded it, under a penalty of £2 a day, it was clear that the works would have to be extended. It was not a question of speculation, but one of fact. There was an almost certain increase of demand to face, and it was absurd to say that they had either to run the existing installation, taking the risk of one of the units breaking down, or to ask sanction for the erection of a new 400-kw. set. It seemed to him that as a matter of business it was wise to go on with the extension. Mr. F. J. Allen, secretary to the Lighting Committee, was examined as to the progress made by electric lighting in the city since the committee began to enter into agreements for the supply of light to the citizens. He stated that the number of agreements in existence at March 31, 1903, was 322. Since then three had been cut off, leaving 319 still working. The new agreements entered into from March 31, 1903, to Oct. 13, 1904, were 580, of which two had been since cut off, and 35 of which were only extensions of alterations. The new agreements entered into showed a steady progress month by month. The total consumers connected to the system on Oct. 13, 1904, was 816, and consumers whose agreements were completed but who were awaiting connection were 45. The total 8-c.p. lamps on the system at March 31, 1903, were 33,000, and from that date to Oct. 13, 1904, after allowance of 58 which had been subsequently cut off, there had been 46,042 installed. The number at present on supply was 79,042, and awaiting connection 6,440. The total demand for 8-c.p. lamps for which the Corporation were liable was 85,482. Mr. Mark Ruddle, resident engineer at the Pigeon House, stated that from his experience he was of opinion that it was necessary to add to the generating plant for the purpose of immediately coping with the demand. The boilers had been immensely improved.

Port Elizabeth. — The *British and South African Gazette* authoritatively announces the settlement of the difference of opinion between Port Elizabeth's borough and consulting engineers as to the most suitable system of electricity supply for the municipality, and that commercial benefits will accrue within the next six or eight weeks. The whole difficulty has arisen out of the fact that insufficient data were originally placed before the consulting engineers in London—Messrs. Robert Hammond and Son. As we have previously announced, the plans of Mr. R. Pape, the borough electrical engineer, provided for direct current on the low-tension system. These plans, together with maps of the town and district, were submitted to Messrs. Hammond and Son for their approval, but were returned with a strong objection to the low-tension system, and an urgent expression of opinion in favour of a high-tension scheme, on the ground that the site of the generating station was not sufficiently central for the successful working of the former. After consultation with Mr. Pape, who arrived in England a week or two ago, Messrs. Hammond and Son have cancelled their objection to the low-tension scheme, and are now engaged with Mr. Pape in drawing up specifications, etc., preparatory to calling for tenders. The report continues as follows: Details of the plant which will be required, and on which an expenditure of £90,000 is at present authorised, are not yet public property, but we are fortunately able to give our readers some hitherto unpublished particulars. The earliest indents will be for three sets of 400-kw. steam-turbine generators, of about 1,800 h.p. total, delivery of which will be spread over a period of 12 months. The first will be required practically at once, and will meet the earliest demands for power. The second will be held in reserve, but it is calculated that the demand for current will double itself in 12 months, so that by the time the third set arrives the first two sets will be working to their full capacity. Even after the erection of these three generators is completed, considerable extensions are expected to prove necessary at an early date. In addition to this heavy plant, large orders are to be given out for cables, lamps, standards, switchboards, meters, fuse boxes, and the many other items of equipment required to complete the full municipal light and power scheme. Arc lamps will be erected in the main streets, but in the lesser thoroughfares the lately-introduced Nernst lamps will be utilised. Apart from the important and immediate orders which the municipal authorities are about to place, the installation of an electricity supply system at Port Elizabeth has a more general commercial significance. A considerable demand for current for industrial purposes is anticipated, and as the local price for gas is 8*s.* 9d. per 1,000 cubic feet, it is probable that electricity will quickly step into favour as a means of domestic lighting and heating. This means that a new trade in electrical fittings and supplies will be created at Port Elizabeth, and a new source of custom provided for manufacturers of lamps, ornamental brackets, insulated wire, etc. It is, by the way, an extraordinary fact that while makers of metal fittings and electric cables and wire are pushing their goods in the South African market, it is an extremely rare circumstance to find any evidence of a desire on the part of makers of electric lamps to secure Colonial trade. In the home market quite a variety of types of the ordinary incandescent lamp for domestic use are receiving constant and wide advertisement, yet brands which are almost household words in Europe and America are only heard of by accident in South Africa. Amongst other orders mentioned, we note that at Kimberley the burgesses have approved the agreement under which the De Beers Consolidated Mines Company will supply current within the municipality. In addition to the electrical works now in hand at Middelburg, Transvaal, the Town Council has before it a scheme for the electric lighting of the cantonments, which will involve the purchase of additional mains, fittings, lamps, etc. Orders consequent upon the decision of the King Electric Power Company, Limited, to extend the present lighting plant and system at Kingwilliamstown, have yet to be placed. At Vryheid the Local Board has two tenders for the electric lighting of the town under consideration. The Johannesburg telephone system is soon to be taken in hand, and when the new exchange is built about 10,000 connections will be available. The instrument to be employed is the Ericsson. Messrs. Harris, Lee, and Co. have secured the concession for the lighting of Bethlehem in the Orange River Colony. The installation involves orders for boilers, engines, dynamos, cables, etc., to a considerable value.

Leeds Hospitals.—The Seacroft and Killingbeck Hospitals were recently opened by the Lord Mayor, the ceremony marking the completion of an undertaking which has been carried out at a cost of £266,000. There are 42 acres of buildings, self-contained and independent as a little town, with generating station, administrative buildings, and school. Mr. E. T. Hall, F.R.I.B.A., was the architect, and Messrs. Arnold and Son were the contractors. The whole of the engineering works were included in the architect's general specification. Messrs. Shepherd and Courtney, Leeds, were the consulting and supervising engineers for the electric plant and installation, and Mr. E. G. Hillier, Manchester, for the boilers and steam-piping. Messrs. Clayton, Son, and Co., Limited, Leeds, were contractors for the engineering works, plant, etc., consisting of three high-pressure Lancashire boilers 28ft. by 7ft. 6in., and three low-pressure boilers 30ft. by 7ft., all complete with Messrs. Hopkinson's mountings, valves, etc. There is a Green's economiser, consisting of 144 pipes, six pipes wide, built in two groups. Messrs. Dargue, Griffiths, and Co., Limited, Liverpool and London, made the connections, etc., consisting of steam-pipes for boilers, electric light, pumps, kitchen, heating, hot-water supply, laundry, etc. The boiler steam mains and connections, consisting of duplicated 6in. cast-iron pipes jointed with Taylor's corrugated copper rings, are taken to two cast-iron steam-separators 15in. bore 3ft. deep below the 6in. branches fitted with inside diaphragm plate and reflex water gauges.

Digitized by Google

The separators are drained by means of a ⅜in. Sentinel steam-trap with valves and by-pass arrangements; duplicated 5in. cast mains are taken across the engine-house with 2½in. bore copper pipes from each main connected to the 2½in. engine stop valves. Cast-iron pipe connections are taken from three 6 × 4 × 6 Worthington pumps for economiser and boiler feed. The whole of the condense from the steam mains, electric and laundry engines, calorifiers, kitchens, laundry, etc., is taken to the cast-iron hot-well fitted at the suction end with three filtering grids so that no water can pass except through the towelling. The well provides hot boiler feed during the day load. The Electric Construction Company, Wolverhampton, were the contractors for the generating sets, consisting of three 50-kw. and one 13k-w. Belliss-Morcom-E.C.C. sets. The dynamos are compounded. The main switchboard contains four dynamo panels, one meter panel, two feeder panels. Each dynamo panel is fitted with ampere and voltmeter, two-way voltmeter switch, shunt resistance switch, two single-pole fuses, one double-pole 200-ampere switch, one circuit breaker, and automatic reverse-current release switch. The meter panel contains two wattmeters for 450 and 150 amperes. The feeder panel contains four ampere-meters reading to 150 amperes, four single-pole fuses, four single-pole switches, four circuit breakers, with automatic overload release, for 150 amperes normal maximum. Messrs. J. H. Taylor and Co., Huddersfield, were the contractors for the feeder distributors, wiring, telephones, fire-alarms, etc. The feeders and distributors, amounting to upwards of 3½ miles of British Insulated and Helsby concentric, lead-sheathed and armoured cables, have been run partly in stone troughing filled in solid with pitch, and partly on multi-step cast-iron brackets in the subways. The feeder, distributor, junction, and service boxes, amounting to upwards of 100, are cast-iron boxes filled in solid with pitch, designed specially by the consulting engineers, and supplied by the British Insulated and Helsby Cables. The wiring is carried out on the double-pole distributing fuse-board system for 2,800 lights, on 2,400 switches. The wires are laid in American whitewood casings of the architect's special rounded section, and looped from terminal to terminal. The casings are multi-grooved—one groove, one circuit. The fittings in the wards are steel-bronzed, plain tube pendants, with loose non-rotating joints. The telephone exchange is arranged for 100 lines. The cables and wires are insulated with pure and vulcanised rubber, enclosed in lead sheathing, partly run underground in wood troughing filled in solid with pitch, and partly in the subways, the connections being made by means of about three dozen connecting cast-iron watertight boxes. The fire-alarm installations, consisting of about 30 bells, are fixed in the various buildings occupied by the staff. The bells are rung simultaneously by means of switches in the gate porter's lodge. The wires are vulcanised rubber, lead-sheathed, and run in wood troughing filled solid with pitch, and laid underground, local batteries being supplied for ringing the bells, the circuit being closed by means of relays. The electric goods lift was supplied and erected by the Leeds Hydraulic and Engineering Company, Limited. Amongst the minor electrical plants we note a 12-h.p. motor in the laundry by Messrs. Dargue, Griffiths, and Co., Limited, electrically-driven bakery plant by Messrs. Morley and Co., Halifax, and a number of electrically-driven labour-saving appliances in the kitchen. Other contractors were: (1) Laundry, 16-h.p. engines by John Fowler and Co., Limited, Leeds, and other machinery by Messrs. Bradfords and W. Summerscales and Sons, Limited; (2) kitchens, the latter firm and Messrs. W. Moorwood and Son and Co.; (3) sanitary engineering and plumbing, H. Braithwaite and Co., Leeds; (4) pipe covering, the non-conductor amounting to 61,000ft. super, supplied by Messrs. J. S. Miller and Co., Leeds, asbestos for high-pressure work and the special covering "Unradium" for low-pressure work. There are eight miles of drains, 26 miles of steam, water, and other pipes, and 46½ miles of electric light and telephone wires, and 80,000ft. of electric light wood casings, etc. It is said that there will not be a penny extra on the contract.

PROVISIONAL PATENTS, 1904.

OCT. 10.

21684. Improvements in alternating-current electric motors. Union Elektricitäts-Ges., 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Oct. 9, 1903, being date of application in Germany.) (Complete specification.)

21694. Improvements in or in connection with electric motor controllers. Henry Vincent James, 3, Brown-street, Market-street, Manchester.

21722. Improvements in rail joints and electrical bonds connected therewith. Richard Heber Radford, 15, St. James-row, Sheffield.

21726. An improved system of suspending conductor wires for the distribution of electrical energy. Albert Enoch Cooper, 118, Abbey-street, Rugby.

21729. Improved swivelling coupling for electric cables. Edwin Burbidge Phillips and Thomas Creswell Parkin, 22, Southampton-buildings, Chancery-lane, London.

21780. Improvements in automatic thermal and magnetic circuit breakers. Robert Starke, 195, Upper Thames-street, London.

21784. Improvements in the method of and apparatus for automatically opening or breaking at predetermined times an electric circuit or circuits. Percy F. Corkhill, 6, Lord-street, Liverpool.

21795. An improved dynamic-electric clutch. Robert von Lieben and Eugen Reisz, 46, Lincoln's-inn-fields, London. (Complete specification.)

21796. Improvements in and relating to controllers for electric motors. Alexander Churchward, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Oct. 10, 1903, being date of application in United States.) (Complete specification.)

OCT. 11.

21819. Improvements in automatically-operated telephonic exchanges for a small number of lines. Albert Morrison Bullard, 55, Chancery-lane, London. (Complete specification.)

21846. Improvements in electric switches. Thomas Ames Cameron, 615, F. St., North-West, Washington, D.C., United States. (Complete specification.)

21848. Telegraph recorder. Willis Joseph Roussel and Alphonse King, 615, F. St., North-West, Washington, D.C., United States. (Complete specification.)

21889. Electric alternating-current machines. Karl Arvid Lindström, 65, Chancery-lane, London. (Date applied for under Patents Act, 1901, Oct. 16, 1903, being date of application in Sweden. (Complete specification.)

21892. Improvements in electric arc lamps. Frank Michael Lewis, Norfolk House, Norfolk-street, Strand, London.

21894. Improvements in regenerative dry batteries. William Hackett Gregory, 53, Chancery-lane, London. (Complete specification.)

21895. Improvements in electric telegraphs. Siemens Bros. and Co., Limited, and George Sylvester Grimston, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

21902. Improvements in and relating to dynamo-electric machines. The British Thomson-Houston Company, Limited, and Reginald Charles Clinker, 83, Cannon-street, London.

21903. Improvements in electricity meters. The British Thomson-Houston Company, Limited, and William John Lloyd, 83, Cannon-street, London.

21911. Improvements relating to electric batteries, electrolytic apparatus, or the like. Pascal Marino, 7, Southampton-buildings, Chancery-lane, London.

21913. Improvements in the manufacture of galvanic cells. Rudolf Ziegenberg, 18, Buckingham-street, Strand, London. (Complete specification.)

OCT. 12.

21966. Improvements in electric heat alarms. Robert William Bill and Sidney Bill, 9, Headingley-road, Handsworth.

21995. Improvements in and relating to intercommunication telephone systems. Isidore Bernard Birnbaum and Herbert George White, 322, High Holborn, London.

22000. Improvements in electric motors. Paul Jigouzo, 40, Chancery-lane, London. (Date applied for under Patents Act, 1901, Oct. 21, 1903, being date of application in France.) (Complete specification.)

22003. Improvements in conduits for electric cables or conductors. Thomas Easton Devonshire, 47, Lincoln's-inn-fields, London.

OCT. 13.

22022. Improvements in the means of operating switches or points of tramways and overhead cables in connection therewith. Philip Reader, 2, Church-gate, Nottingham.

OCT. 14.

22085. A wireless telegraphy receiver capable of recording or printing only waves of a given strength. Francis Patrick Reid, 37, West Nile-street, Glasgow.

22100. Improvements in or relating to certain parts of electrical circuit breakers and automatic switches. The Electric and Ordnance Accessories Company, Limited, and Robert Frederick Hall, 24, Temple-row, Birmingham.

22113. Improvements in apparatus for automatically operating the points of electric tramways. William Redfern Evans, 55, Market-street, Manchester.

22156. Improvements in commutators for dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22157. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22164. Improvements in or relating to apparatus for use in the distribution of alternating electric current. Arthur Francis Berry, 46, Lincoln's-inn-fields, London.

22171. Improvements in connection with electric switchboards to protect persons from injury. The Elektrizitäts Akt.-Ges. vormals W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Dec. 31, 1903, being date of application in Germany.) (Complete specification.)

22173. Improvements relating to electric heating. Francis Edward Spon, 22, Southampton-buildings, Chancery-lane, London.

OCT. 15.

22236. Improvements in electric lamp fittings. Albert John Bonnella, 9, Warwick-court, Gray's-inn, London.

Digitized by Google

22206. Electromagnetic press. Sir Benjamin Scott (Knight), Edwin Herbert Quarrington, and Tom Hill Hodgkinson, James-street, Carlisle.

22210. An improvement in or in connection with dry voltaic cells and primary batteries. Clarence Metcalfe Stead, 30, Park-row, Leeds.

22213. An improved electric wire terminal clip. George Robinson Cartmel, Palatine-chambers, Market-street, Halifax.

22246. Improvements in and relating to the distribution of electricity for electric traction. Charles Gibbs, 70, Chancery-lane, London.

22247. Improvements relating to electric lamps. Armistead Keith Baylor, 83, Cannon-street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Nov. 3, 1904.

1903.

15077. Automatic switchboards for telephone and like exchanges. Hanson. (Date applied for under International Convention, July 7, 1902.)

22953. Dynamo-electric machines. Martin, Lowson, and Sayers.

22440. Telephone systems. Fairweather. (Kellogg Switchboard and Supply Company.)

23110. Electric potential governors. Boyden.

23478. Electrical transmissions of energy through space. Artom. (Date applied for under International Convention, Aug. 23, 1903.)

25525. Electric starting switches for electric motors and the like. British Thomson-Houston Company, Limited. (General Electric Company.)

25663. Telephone systems. Falk, Stadelmann, and Co., Limited, and Thurnauer.

26488. Electrical ignition apparatus for internal-combustion engines and the like. Napier.

26533. Electric heaters. Krause.

26553. Apparatus for electrically igniting miners' safety lamps. Best, Best, and Best.

26557. Electric arc lamps. Crompton and Co., Limited, and Hodgson.

27350. Electric gas or vapour lamps. Le Tall. (Potter.)

28748. Trolley wheels or collectors for electric currents. Estler and Jack.

1904.

653. Casings for dynamo-electric machines. Saarbrücker Elektricitäts Akt.-Ges. and Emmerich.

2899. Electric signalling systems for railways. Struble. (Date applied for under International Convention, Feb. 13, 1903.)

3540. Alternating-current integrating and indicating watt-meters. Conrad. (Date applied for under International Convention, Feb. 20, 1903.)

3365. Storage batteries or accumulators. Fairweather. (Vesta Storage Battery Company.)

15226. Method of selecting electrical impulses. Troy. (Date applied for under International Convention, July 11, 1903.)

16396. Method of producing zinc from sulphate solutions by electrolysis. Abel. (Siemens und Halske Akt.-Ges.)

17236. Post for electric conductors, lamps, trolley lines, and the like. Weller.

17483. Receiving system for wireless communications. Harrison. (Date applied for under International Convention, Aug. 27, 1903.)

17792. Manufacture of incandescent electric lamps. Canello. (Date applied for under International Convention, Sept. 12, 1903.)

18949. Safety guard for conductor or live rails of electric railways. Sale.

19245. Automatic signalling for electric railways or tramways. Wilson and Marshall.

19611. Controlling apparatus for electric motors. Klinkenberg.

NOTES.

The Royal Sanitary Institute.—His Majesty has been graciously pleased to confer the title "Royal" upon the Sanitary Institute, and to signify his pleasure that the institute be known as the Royal Sanitary Institute.

Rontgen Society.—This institution will open its session on the 3rd prox., when the presidential address will be delivered. The following dates for general meetings have been provisionally arranged: Dec. 1, Jan. 6, Feb. 3, March 2, April 6, May 4 (exhibition evening), June 1, and July 6 (annual meeting).

Faraday House.—Judgment was given in the action Eason *versus* the Syndicate of Electrical Engineers, Limited, on Tuesday, in favour of the defendants, with costs. This was an action in reference to ancient lights at the back of the new Faraday House in Southampton-row, and we are glad to note that the Electrical Standardising Institution has been successful in resisting it.

Electrolysis of Water-Mains.—The report of the Metropolitan Water and Sewerage Board of Boston, U.S.A., after commenting upon the large degree of electrolysis sustained by the water and drainage mains, observes that an insulating joint with a connection made of rubber gasket ½in. thick, placed between two flanges, has been found useful in preventing the flow of electricity from adjoining pipes.

High-Voltage Experiments.—Some time ago a considerable sum was contributed in America to enable Mr. R. W. Mershon to take up certain high-voltage experimental work, the results of which he will describe in a paper. The preparations for this work, which will be carried out on the American side of the Niagara Falls, are practically completed, and the tests will be commenced very shortly. It is proposed to take measurements on an experimental line up to at least 100,000 volts, and possibly as high as 200,000 volts.

Electric Fire-Alarms for Theatres.—We are pleased to see that the May-Oatway fire-alarms recently installed in the Theatre Royal, Edinburgh, have already proved of service. There was a fire in the theatre on Tuesday last during a rehearsal, and the Edinburgh fire brigade was called automatically to the spot by the electric fire-alarm. In the meantime the theatre staff had succeeded in extinguishing the fire, but the prompt call to the brigade would have been of inestimable service had the fire proved too much for the theatre staff. We understand that this is the first fire in a theatre of the United Kingdom which has been so reported, but there are four Scotch theatres which have this safeguard. Owing to the refusal of the London fire brigade to have this automatic signalling in their stations, this form of protection is not used in any London theatre. We think, however, it is time that the County Council reconsidered their decision on this point.

Brighton Telephone Service.—The municipal telephone service was opened on Oct. 5 of last year, when the number of instruments connected was 12. On the anniversary of that date 1,448 instruments were working, in addition to which there were 21 junction lines. The construction of over 1,400 stations in 12 months compares favourably with any similar undertaking in the country, especially as the Council thought at one time that a 1,000-line exchange would suffice. All the subscribers in Brighton, Hove, Preston, and Kemp Town are connected directly with the central exchange, ensuring a quicker service than with a number of sub-stations. In another column we publish an approximate revenue account for the six months ending Sept. 30. From this it will be seen that after charging all working expenses, interest, and sinking fund, a balance of £98 remains. The revenue during this period averaged £411 per month. It is anticipated that the account for the year on March 31 next will show that the revenue has been sufficient to cover all expenses, including capital charges, and show a substantial balance. The committee and the engineer are to be congratulated upon such an excellent result.

London Traffic.—The chairman of the Highways Committee of the London County Council has returned from the United States, whither he proceeded a few months ago to study the traffic problem, a confirmed believer in the conduit system for the tramways of the Metropolis. He was greatly impressed with the conduit trams of New York, which run the entire length and breadth of Manhattan Island, and would have the arrangement duplicated here by a line from Shepherd's Bush to Stratford, running right through the City, and another from Highgate to Streatham. To this, and a shallow underground railway with similar ramifications, Mr. Baker looks for a solution of the traffic problem. Few, however, will expect to find the former included when the London Traffic Commission issues its recommendations. Two features in the New York tramway service attracted Mr. Baker's attention. Higher speeds prevail than in London, and there are no restrictions on overcrowding. Mr. Baker thinks that some revision in the latter respect may be necessary here. There would probably be little harm in allowing a certain degree of latitude, as is done in some of the provincial towns, but the desirability of unlimited overcrowding may well be questioned.

Tram Accident.—As one of the Brighton Corporation's cars was ascending Elm-grove the other day some leaves from the adjacent trees were crushed under one of the wheels, causing insulation. The car began to travel backwards, but an application of the slipper brake promptly checked the speed, with the result that at the foot of Elm-grove the car turned a curve without accident. Having reached level ground, the car was brought to a standstill. Meanwhile the passengers had taken alarm, and a number of them crowded on to the platforms. Apparently none of them attempted to jump off, but owing to the pressure of those behind five were thrust off, and in falling two of them were rather badly hurt. The moral of the accident is the same as can be drawn from practically every tram accident—*i.e.*, that it is safest for the passengers to remain in their seats. Our readers will perhaps remember an accident of a similar character a year or two ago at Glasgow, in which the injuries were considerably more than at Brighton. In this case the tram, after running down a hill backwards, finally broke into a shop. The construction of the car was so substantial, however, that not even the windows were broken. The passengers who sat still were also uninjured; but it is a difficult matter to educate the public in this respect.

The Tubes and Hygiene.—The *Lancet* considers that the tube railways adopted a mistaken policy in having one class of train only. Further, it charges the companies with providing inadequate ventilation. When the compartments, remarks our contemporary, are full, the characteristic sickening smell of human exhalation is most revolting to the passenger entering fresh from the outside air. This leads the *Lancet* to ask, Why, if the tunnels are well ventilated, as stated, cannot the train partake of this ventilation, instead of the doors being closed as soon as the train leaves the station? This question seems a reasonable one, and worthy of attention on the part of the companies. On the question of classes, our contemporary

Digitized by Google

observes that in a one class compartment the cleanly-disposed are compelled to be wedged in amongst the indifferent, and it believes that many passengers, especially ladies, would willingly pay a higher fare to travel in a distinct compartment, not from social considerations, but in order to secure greater comfort and a better sanitary environment. Such an arrangement would, our contemporary predicts, amply pay the companies. This does not seem to quite accord with the experience of the steam lines. Probably the provision of, at any rate, one distinct car in each train would meet with considerable appreciation. It would, however, lengthen the period of stopping in each station, and thus delay everyone.

Salaries of American Locturers.—At the farewell banquet given in his honour by the physical science departments of the Brooklyn Institute of Arts and Sciences at New York, Sir William Ramsay had something to say upon the remuneration of those engaged in teaching science in America. In the course of his remarks Sir William stated that during his sojourn in the States he had been greatly impressed by the high power of organisation displayed by leading manufacturers and commercial men, but had also learned that men employed in a scientific capacity, especially those engaged in teaching the science, were receiving less than they would earn if they were engaged in industrial pursuits. "This condition of affairs," said Sir William, "unless remedied, and remedied soon, before long will lead to the lowering of the whole educational status, for it will inevitably react upon the training of professional and scientific men in this country. If trained by third-rate teachers—as they must be—it is unlikely that they will take the rank which they would have taken if their teachers had been men of first-rate ability." It was not necessary, Sir William added, that every professor should receive high emoluments, but he considered that those who filled the most important positions in the leading universities of the country should be well paid. He recommended that some of the donations from public benefactors, instead of being devoted to the erection of new buildings, should be used to increase the emoluments of existing chairs.

Association of Technical Teachers.—Meetings of teachers engaged in London polytechnics, technical institutes, and kindred foundations were held in the summer, at which the formation of an association of technical teachers was discussed, and the principal aims and objects agreed upon. The main objects comprise the advancement of technical education generally, the interchange of ideas or methods of teaching, and the safeguarding of professional interests. At a further meeting held at the Birkbeck College on Saturday, Mr. W. J. Lineham (Goldsmiths' Institute), who presided, remarked that the distinct interests of technical teachers rendered such an association necessary. It was proposed, he said, that the association should, in the first instance, be formed for the county of London, but ultimately it might become a national institution. Similar societies in Manchester and the West Riding of Yorkshire had, in fact, intimated their willingness to join a national movement. There are already organisations of teachers in elementary and secondary schools, and the promoters consider that a federated committee of the various associations would be of considerable assistance to the Board of Education. The following resolution was carried: "That this meeting hereby decides to form an association of science, technology, and art teachers engaged in the London polytechnics, technical institutes, and schools of art, such association to comprise both permanent staffs and evening teachers, other than those engaged in purely secondary work." An executive has been appointed to formulate the constitution, and to report to a general meeting in January.

Seats for Tramway Employes.—The report of the Highways Committee presented to the London County Council on Tuesday dealt with the question of providing seats for drivers and conductors. With reference to the former the committee have come to the conclusion that, having regard to the operations which a motorman has to perform in dealing with the controller, the electric and hand brakes, the foot-gong, and the sand pedal, it would be quite incompatible, either with the efficient working of the tramways or the safety of the public, that the motormen should be allowed to sit down while at their work. With reference to the provision of seats for conductors, the committee consider that, having regard to the large carrying capacity of the cars, to the number of short ½d. stages which are so extensively used by the public, and to the importance of the conductor being in a position to attend to intending passengers, and to assist persons in mounting and alighting from the cars, it would be very undesirable that this practice should be adopted. The committee point out that the men have already serious difficulty in collecting all the fares between the different stages. As an experiment the committee gave instructions some time ago that conductors should be allowed to rest against the end of the cars when not engaged. This was found to be unsatisfactory, as the conductors failed to notice many people who were waiting for cars at stopping-points. In the course of the discussion that ensued, Sir William Collins, speaking as a hospital surgeon, stated that the provision of seats would make an immense difference to the health as well as the comfort of the men. No decision has yet been arrived at.

Inspection of Electrical Equipment.—A paper on "Maintenance and Inspection of Electrical Equipment" was presented by Mr. J. Lindall, of the Boston Elevated Railway, to a meeting of the American Street Railway Association at St. Louis. An abstract of the paper appears in the *Electrical Review* of New York. After suggesting that the practice of supplying railroad literature to motormen and conductors should be extended to inspectors and repair men, the author emphasies the necessity of inspection of electrical equipment being systematic. Mr. Lindall remarks that the question of how often to inspect depends entirely upon the equipment and conditions of operation, but as the primary object is to prevent failure, the cost of inspection should be weighed against the direct loss in wages of trainmen while handling crippled cars, and the loss of patronage due to interrupted service. Under the system employed by the Boston Elevated Railway, surface lines, trolleys, switches, controllers, and motors are inspected after three days' service. Some of the cars which operate under particularly heavy work are inspected daily. In addition to this inspection, there is a monthly inspection which consists of opening up motors and cleaning and lubricating all the parts. Controllers are taken apart yearly, and thoroughly cleaned and painted. The wires are also inspected yearly for insulation weakness. The system employed on the elevated roads does not differ materially from that used on the surface roads. The equipment is inspected twice a week, and the controlling mechanism is tested. The best system of inspection, concludes the author, is one that is frequent enough to take care of the equipment properly with the least inconvenience to the service.

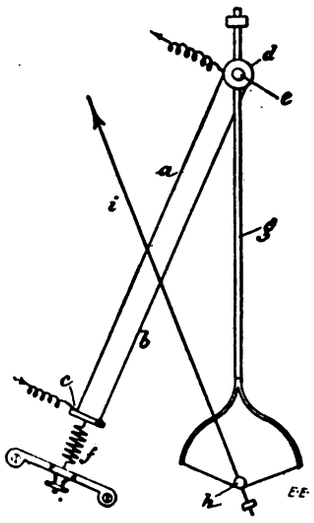
Electro-Therapeutics.—An animated discussion on the treatment of cancer occurred at the recent Dermatological Congress at Berlin. Prof. von. Petersen

Digitized by Google

spoke on the subject of non-surgical treatment, and came to the following conclusions: (1) that epithelioma is curable without operation only in its initial stage; (2) that the best results are obtainable by "Finsenlicht," inasmuch as this treatment has no deleterious effects, though, unfortunately, it is very expensive; (3) that Röntgen rays are often productive of good results, but they must be employed with great caution; (4) radium rays give positive results, but are accompanied by dangers still greater than those arising from the use of Röntgen rays; (5) small surface epithelioma can be healed by continued bandaging with a solution of from 5 to 15 per cent. of soda. Prof. von Bergmann maintained that every kind of epithelioma can be permanently healed by means of surgery, whereas only a portion of the cases are healed by treatment by light. He admitted that when severe complications already existed the surgeon could not cure the patient. But in those cases the Röntgen rays also failed. Hitherto, he said, no cancer which has proved impossible to operate for had been healed by the Röntgen rays. It was true that in perfectly hopeless cases the pain of the patients could be alleviated by Röntgen and radium rays, but this simply meant the prolongation of the life of the patient and not his cure. Dr. Leredde, of Paris, stated that a clever doctor could always avoid causing harmful effects when using radium in cases of cancer. He had obtained good results from the use of radium. The president of the congress pointed out that a careful distinction must be drawn between the different kinds of epithelioma. Deep-rooted cancer, he thought ought to be operated upon immediately if an operation were possible, but superficial epithelioma should be treated by Röntgen rays.

Shoreditch Electrical Exhibition. — To commemorate the exhibition undertaken by the Shoreditch Borough Council, the exhibitors gave a dinner and smoking concert to a large assembly of guests on Monday at the Great Eastern Hotel, the Mayor, Councillor H. B. Bird, J.P., being in the chair. From all indications this exhibition has been a decided success. No fewer than 24,000 visitors inspected it, and Mr. C. Newton Russell, the borough electrical engineer, expressed his belief that the seed thus sown would fall on fruitful ground. In the course of his excellent speech in reply to the toast in his honour, he specially associated his staff with his own efforts in organising the exhibition, and predicted that its benefits would be particularly apparent in a great accession to the number of small power users. Monday's pleasant function demonstrated that Mr. Russell's talents are not confined to matters electrical, his rendering of "The Bandeleiro" being much appreciated. In regard to the excellent dinner provided, the novel menu seems to merit preservation as a memento of the compiler's genius: "Crême à la Russell; anti-sulphuric; boiled cable in bitumen sauce; cut-outs on shorts; contractor cutlets with earths; exhibitor's delight; L.C.C. regulations; hot bearings; hashed specifications; armature salad; welded joints; boiled shear-legs; baked field coils; casual enquiry; units; balancers." After this the company were regaled with an entertaining vocal and instrumental programme, and conviviality was the order, notwithstanding the efforts of one gentleman with bellicose tendencies to introduce Mars. When the organising secretary, Mr. C. S. Syer, gave "The Death of Nelson," this gentleman sighed for the resuscitation of the naval hero for the edification of the Russian Baltic Fleet. This in no wise detracted from the harmony, which reigned supreme throughout the evening. Messrs. H. F. Joel, Marryatt, and A. W. Penrose were responsible for some felicitous remarks in proposing the various toasts.

Hot-Wire Measuring Instruments.—A description appears in the *Electrical World* of New York of the Whitney Electrical Instrument Company's new design of voltmeters and ammeters of the hot-wire type. The principle on which these instruments operate is novel, and it is claimed that they constitute a distinct advance in the art of measuring apparatus of this class. The underlying principle is illustrated in the accompanying diagram. A wire, *a-b*, of high resistance, low temperature coefficient, and non-oxidisable metal, is secured at one end to a plate, *c*, passed around a pulley, *d*, secured to a shaft, *e*, and its free end brought back again and mechanically, though not electrically, attached to the same plate, *c*. Plate *c* is kept under stress by the spring, *f*, which constantly tends to pull it in a direction at right angles with the axis of the shaft, *e*, and is so guided that it can be moved in that one direction only. To the shaft, *e*, is likewise an arm, *g*, bifurcated at one end and counterweighted at the other. Between the extremities of the bifurcated ends of the arm, *g*, is another shaft, *h*, on which there is a small pulley, and to which is attached the needle, *i*, that gives the desired indications. A fine silk fibre is attached at one end to one of the arms of *g*, then passes around the pulley and the shaft *h*, and finally has its other extremity secured to the other arm. The arms are springy, and serve to keep the silk fibre



taut. The current to be measured flows through the wire *a*, only, entering and leaving as indicated by the arrows. Evidently, when *a* is heated by the passage of current, it expands, which, as *a* and *b* were originally under the same tension, makes *a*'s tension relatively less than that of *b*, and equilibrium can be restored only when the pulley, *d*, rotates sufficiently to again equalise the strain. The rotation of *d*, of course, carries *g* with it, and *g*, in moving, causes the silk fibre to rotate the shaft which carries the needle. If the temperature of the air surrounding the instrument changes, *a* and *b* are affected alike, and their resulting equal expansion simply results in a movement of the plate, *c*, back or forth in its path without any tendency to rotate the pulley. The advantages claimed for this design include perfect compensation and very limited tension on the wire. The new instruments being normally worked at a lower temperature than former types, there is a margin of safety such that an overload sufficient to cause the indicating needle to swing over 120deg. beyond the extreme normal limit of the scale when the cap is removed may be carried continuously without even affecting the calibration. The zero adjustment used is also novel. The entire moving system, shown in the diagram, is mounted on a single base plate free to rotate over a small angle around a heavy shaft

Digitized by Google

secured to it immediately below and in line with shaft *h*, around which the needle swings. By means of a lever secured to this base plate and projecting slightly beyond the cap that covers the mechanism, the position of the needle relative to the scale may be altered at will without interfering with the wire in any way. While already nearly dead-beat in their action the instruments are provided with an auxiliary damping device, consisting of an aluminium disc secured to the shaft to which the needle is attached and swinging between the jaws of a small permanent magnet.

Electrolytic Oxidation of Hydrocarbons.—At a meeting of the Faraday Society on Tuesday, Messrs. H. D. Law and F. M. Perkin presented a paper on the electrolytic oxidation of hydrocarbons of the benzene series. The paper dealt with the methyl group, comprising toluene, ortho-xylene, meta-xylene, and para-xylene, mesitylene, and pseudo-cumene. The authors had repeated Renard's experiment in regard to toluene with somewhat different results, particulars of which will be communicated in a future paper. The oxidation of the xylenes brought out points of considerable interest. It was found that with ordinary oxidising agents the three xylenes behave very differently. Thus ortho-xylene, when subjected to the oxidising action of chromic acid, is completely decomposed with carbonic acid and water, whereas both meta- and para-xylene yield the corresponding dicarboxylic acids. Dilute nitric acid converts ortho-xylene into ortho-toluic acid, and para-xylene into para-toluic acid, but has no effect upon meta-xylene. Potassium permanganate, on the other hand, yields the corresponding dicarboxylic acids. The electrolysis was carried out in a rectangular glass battery jar of about 1,200 cubic centimetres capacity, which was placed in a vessel through which cold water was caused to slowly flow. The cathode compartments consisted of two narrow porous cells, which were placed against opposite sides of the battery jar, and contained cathodes of sheet lead. The electrolyte in the cathode compartment is either acid of the same concentration as that employed in the anode cell, or a 15 per cent. solution of sodium sulphate. When sulphuric acid is employed, it is necessary to refill the cells every 24 hours or so, owing to the depletion of the electrolyte through the migration of the SO_4'' ions. In the centre of the anode cell is placed a glass stirrer, worked by a water-turbine or electromotor, and on either side of it two platinum gauze or sheet platinum electrodes, each having half a square decimetre of surface; or two gauze electrodes of one square decimetre surface are fixed about 1 cm. from each of the porous cells, this latter arrangement having the advantage of lowering the E.M.F. A current density of from one to two amperes per square decimetre is usually employed. A great difference of action is exhibited by slight modifications in the mode of conducting the electrolysis.

Electrical Extraction of Nitrogen from the Air.—A paper on this subject, of which an abstract appears in *Electrochemical Industry*, was presented by Mr. J. S. Edstrom to Section C of the International Electrical Congress. The author, having indicated the necessity of making provision against the exhaustion of the Chili saltpetre mines, deals with other means of producing compounds of nitrogen. The nitrogen in the air is the source which has most naturally been turned to in seeking to produce a commercially useful article. Having reviewed the work of other experimenters, the author describes the process of Messrs. C. Birkeland and S. Eyde, of Christiania, which is based on a compound with oxygen. This process is founded on the fact that the current in the arc, and with it the arc itself, can be deflected by a magnetic field, the deflection being at a right angle to the lines of force. If the horizontal electrodes are connected to a generator in series with a suitable inductance coil, and a strong magnetic field is applied near the electrodes in horizontal direction and at a right angle to the direction of the electrodes, the arc between the electrodes will momentarily be carried upward or downward. It will then be broken, while simultaneously a new straight arc is formed between the electrodes, which is

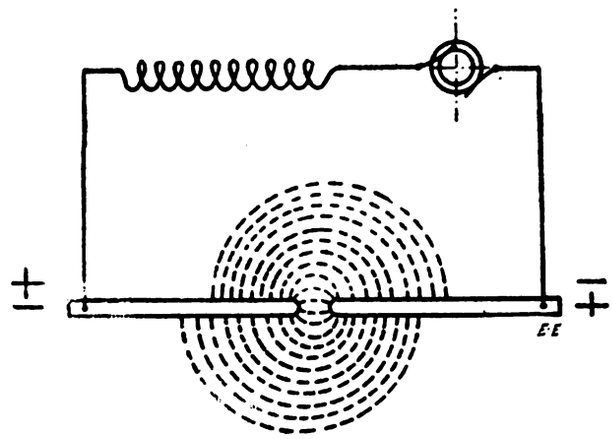


FIG. 1.

again carried outwards, etc. The speed of the formation, motion, and breaking of the arcs is so rapid that the arc can be formed several thousand times a second. In the practical form of the ovens only some hundred arcs per second are used. If the magnetic field is excited by a direct current, and the generator delivers direct current for the arc, a continual series of arcs will be formed moving radially with a speed corresponding to the strength of the magnetic field. The striking points of the arc along the surface of the electrodes are also moving away from the points at

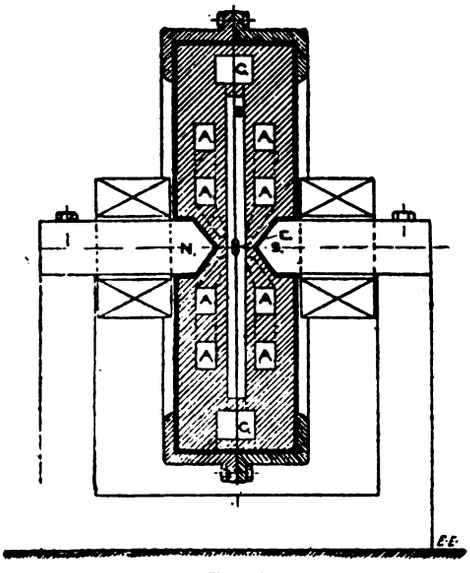

FIG. 2.

the same speed. Thus, the phenomena appear to the eye like a disc of arcs in the shape of almost a complete semi-circuit. The movement of the arc near the electrodes is usually more rapid at the negative than at the positive electrodes, shifting the centre of the circular disc somewhat to one side of a line joining the electrodes. If the magnetic field is excited by alternating current, and the arc is fed by direct current, the arcs will vibrate between opposite sides of the electrodes. This will also be the case if the arc is fed by alternating current and the magnetic field by direct current, in which

Digitized by Google

case the phenomena will appear as indicated in Fig. 1. In Fig. 2 is shown the electric oven complete in a vertical section at right angles to the electrodes. The air that is to pass the oven is forced through the channels, A, and thence into the arc chambers of the oven, B, around and in the neighbourhood of the electrodes, E. Having passed this space from the centre, and coming into intimate contact with the disc of arcs, the air passes out into the channel, C, leaving the oven mixed with a certain percentage of oxidised nitrogen. The advantage of this apparatus is that the economical efficiency increases with the amount of energy employed at the electrodes. In spite of the relatively large current which can be employed in this type of oven, the electrodes exhibit marked durability.

Tests on a Transformer having High Electrostatic Capacity.—In a contribution to the *Elektrotechnische Zeitschrift*, L. Lichtenstein deals with some tests carried out on a high-tension alternate-current transformer built by the Siemens-Schuckert Company, and having a primary consisting of 2 × 30 turns of ·066 square inch section copper strip with a resistance of ·0096 ohm per limb, and a secondary winding of 2 × 30,000 turns of ·01in. diameter copper wire giving a resistance of about 12,150 ohms per limb. The low-tension primary coils were permanently coupled in parallel, whilst the high-tension secondary ones could be coupled either in parallel

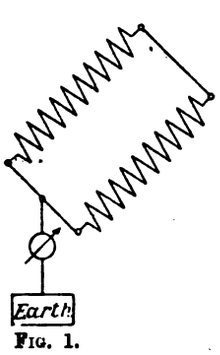

Fig. 1.

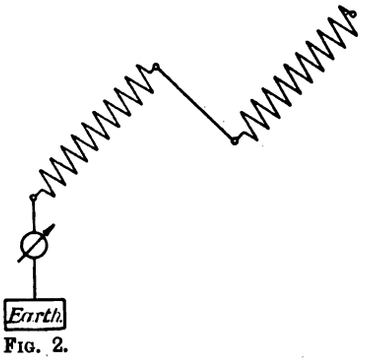

Fig. 2.

or in series. In this way the ratio of transformation could be made either 1 : 1,000 or 1 : 2,000, and as the primary was designed for about 100 volts at 50 ⁓, a secondary voltage of 200,000 could be attained. The secondary current with the limbs in series was ·05 ampere, so that the normal output of the transformer was 10 kw. It was noticed that on test with open secondary circuit, the primary current, at constant primary voltage, reached a different value according to whether the high-tension secondary limbs were connected in parallel or in series. A series of further tests was therefore carried out, and showed that there were also differences of primary current according to whether one pole of the secondary was earthed or both poles were insulated. The following table shows the results of the various tests :

Primary voltage.	Primary current.	Secondary voltage.	Secondary current.	Primary power factor.	Arrangement of the secondary as in
45·2	8·78	45,200	·00844	·858	Fig. 1*
45	13·38	90,000	·0133	·686	Fig. 2†
45	8·65	90,000	·00496	·852	Fig. 3*
45·2	10·4	45,200	—	·614	Figs. 4A and 4B*

* Primary coil lagging. † Primary coil leading.

It will be seen that merely changing the secondary coupling affected the primary current to the extent of about 50 per cent. The explanation is to be found in the fact that the great number of turns in the secondary gives the latter an appreciable capacity. This causes a charging current to be set up whose value depends on the coupling up, and these currents react on the primary current as shown in the table. The correctness of this explanation was confirmed by direct measurement of the charging current by means of a standard voltmeter (dynamometer) calibrated as a milliampere-meter, and having an internal resistance of 10,000 ohms. Since the charging current, as in the case of a cable on open circuit, is different at different points, the milliampere-meter had to be inserted at the point of maximum current. This point, when the two limbs are in series and both poles insulated, is in the middle of the winding—*i.e.*, midway between the two limbs (Fig. 3). When one pole is earthed the point of maximum current is in this earth connection (Fig. 2). This is also the case when the two limbs are in

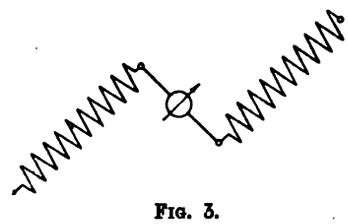

Fig. 3.

parallel with one pole earthed (Fig. 1). With the limbs in parallel but insulated at both poles the point of maximum current occurs midway along the winding of each limb, but in this case it was not possible to obtain direct measurements of the secondary currents. The primary current was, however, found to be the same whether the secondary limbs were connected or not (Figs. 4A and 4B). The various current measurements obtained are shown in the fourth column of the table. The seventh column shows that the primary current is a leading one in the case of the Fig. 2 connection, so that the capacity of the winding was sufficient to actually reverse the phase relation of the primary current. This question of the leading or lagging nature of the primary current was determined by successive measurements of the current at constant primary volts : (1) with a choking coil in parallel with the primary, (2) with the choking coil alone, and (3) with the transformer alone. By applying the vector diagram for the three currents it was easy to determine definitely whether the primary current was a leading or a lagging one. In conclusion, the writer proceeds to compare the test results with calculated results on the assumption of uniformly distributed capacity per unit length of secondary winding and for a sine wave of E.M.F. He shows that the maximum secondary currents measured by the ammeters in the arrangements indicated by Figs. 1, 2, 3, and 4 respectively should be in the ratio of 2 : 4 : 1 : ·5, whilst the actual measurements for Figs. 1, 2, and 3 gave currents in the

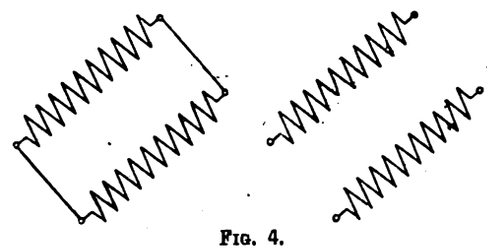

Fig. 4.

ratio of 1·7 : 2·68 : 1. This is as good an arrangement as could be expected considering that the assumptions made do not accurately represent the conditions. The whole capacity of the winding calculated from the currents and voltage measured with the Fig. 2 arrangement is about ·001 microfarad. It is clear that such a transformer might easily lead to resonance effects, for even with open secondary circuit all the components of a resonant circuit are present, the secondary leakage flux forming the self-induction and the capacity being the capacity of the winding itself. The comparatively frequent occurrence of voltage rises when making insulation tests may perhaps be explained in this way.

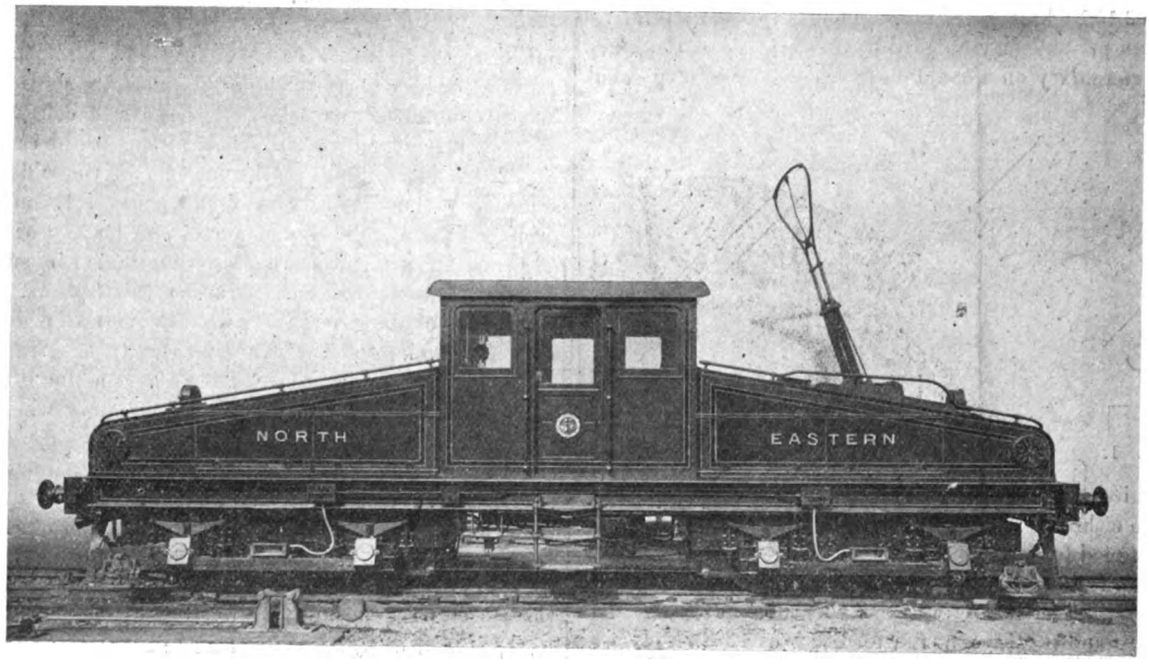
ELECTRIC GOODS LOCOMOTIVES FOR THE NORTH-EASTERN RAILWAY COMPANY.

Through the courtesy of the British Thomson-Houston Company, we are able to give the following details of the heavy electric goods locomotives they have supplied to the North-Eastern Railway Company. These locomotives are for use on the electrified sections of the company's lines round Newcastle-on-Tyne, and are constructed to haul heavy loads. For instance, according to the specification of the consulting engineer to the railway, Mr. C. H. Merz, each locomotive is capable of handling a 300-ton train on the level and of hauling it at a speed of 14 miles per hour. When working on grades under all conditions of weather, the locomotives are also capable of starting a 150-ton train up a grade of 1 in 27, and of running up this grade at a speed of nine to ten miles per hour. From this it will be seen that these locomotives, which weigh about 50 tons, are quite capable of handling the heavy goods traffic such as is found on the lines round Newcastle-on-Tyne. We are pleased to state that the whole of these locomotives were made in England. Thus the trucks and cabs were built by the Brush Electrical Engineering Company at Loughborough, and the electrical apparatus, with the Sprague Thomson-Houston multiple-unit system of control, were supplied by the British Thomson-Houston Company from Rugby. From actual trials we understand that the locomotives are able to exceed considerably the demands of the specification.



Side View of the N.E.R. Electric 50-ton Goods Locomotive made by the British Thomson-Houston Company.

As will be seen from the two illustrations given herewith, the locomotives are of the double-bogie type with a central cab and sloping ends. The four motors are of the G.E.-55 type with two-turn armatures and 3 28 to 1 gear ratio, one being mounted on each of the four axles. The control adopted is the Sprague-Thomson-Houston multiple-unit system, and is similar to that used on the passenger trains. The following are the leading dimensions: gauge, 4ft. 8½in.; length over central cab, 9ft. 0½in.; length over headstocks, 35ft.; length over buffers, 37ft. 11in.; pivotal centres of trucks, 20ft. 6in.; wheel base of each truck, 6ft. 6in.; width over cab, 7ft. 6½in.; width over side soles, 7ft. 10⅝in.; width over all, 8ft. 8in; height from rails to top of cab, 11ft. 9in; height from rails to top of floor, 4ft. 3¾in.; diameter of wheels, 3ft.; diameter of axles at centre, 6⅜in.; diameter of axles at wheel seats, 7 28; diameter of axles at journals, 6in.; length of journals, 10in.

The trucks are of the steel-plate frame type, in accordance with English railway practice, strengthened with steel angles and gussets with swinging bolster built up with steel sections and steel castings. The bolster is supported on two nests of coil springs of circular section, and is provided with cast-steel wearing plates, cast-steel centre, and side bearing plates. The side frames are supported on the axle boxes by laminated springs of heavy design. The axle boxes are of cast steel, machined to work in the horn plates, which are also of steel and machined, being riveted to the side frames, which are cut out to receive them. The axle boxes are provided with wings to take the shoe beams, and are fitted with heavy brasses babbitted. Ample provision is made for lubrication and exclusion of dust. The brake gear is of specially heavy design, as it plays an important part in the work that the locomotive has to handle, which is chiefly on heavy grades. Blocks are fitted to each side of each wheel, and all gear is heavy enough to stand operation by air pressure. The wheels are of the cast-steel disc type, balanced, and fitted with rolled-steel tyres 5½in. wide by 2½in. deep on tread, held in place by retaining rings and also by eight set screws. The motors are carried on the transoms by means of cast-steel brackets, in which the nose on the motor rests, being held there by a forged strap. The shoe beams are of oak, and bolted to the axle boxes, the shoes being hung outside the wheel base as shown on the drawings. All holes are drilled, edges of plates planed, and rivets hand riveted.

The underframe is constructed of steel sections, and ballasted with cast-iron blocks to bring up the weight desired. Each side sole is formed by a girder 12in. by 6in. by 54lb., and of I section. There are two centre longitudinals, each 8in. by 3½in. by ⅝in., of channel section, these four longitudinals being connected at their ends by headstocks 15in. by 4in. by ½in., of channel section. To the front of these is bolted oak headstocks 15¾in by 8in. The whole frame is firmly riveted together with steel angles and gussets, all holes being drilled and edges of plates machined. The underframe bolster is formed by two girders, each 6in. by 5in. by ½in., of I section, held together on the top by a plate 3ft. wide and ⅜in. thick, on the lower side being a plate 17in. wide by ⅜in. thick. Between the bolsters evenly spaced there are five cross girders, each 8in. by 3½in. by ⅝in, of channel section, backed with a plate 15in. wide by ⅜in. thick. On the top of the frame is a floor of fireproof wood 1⅞in. thick, fixed transversely, with a top or lining floor of ⅞in. thickness laid longitudinally. The draw gear, side couplings, and buffers are of the standard English pattern.

The centre cab is constructed of ⅛in. steel plate and angles, and is separate to the sloping ends, which are also constructed in a similar manner, all three portions being bolted to the underframe. The cab is provided with two side windows on each side, the one at the driving corners being arranged to lower. A sliding door is fitted on each

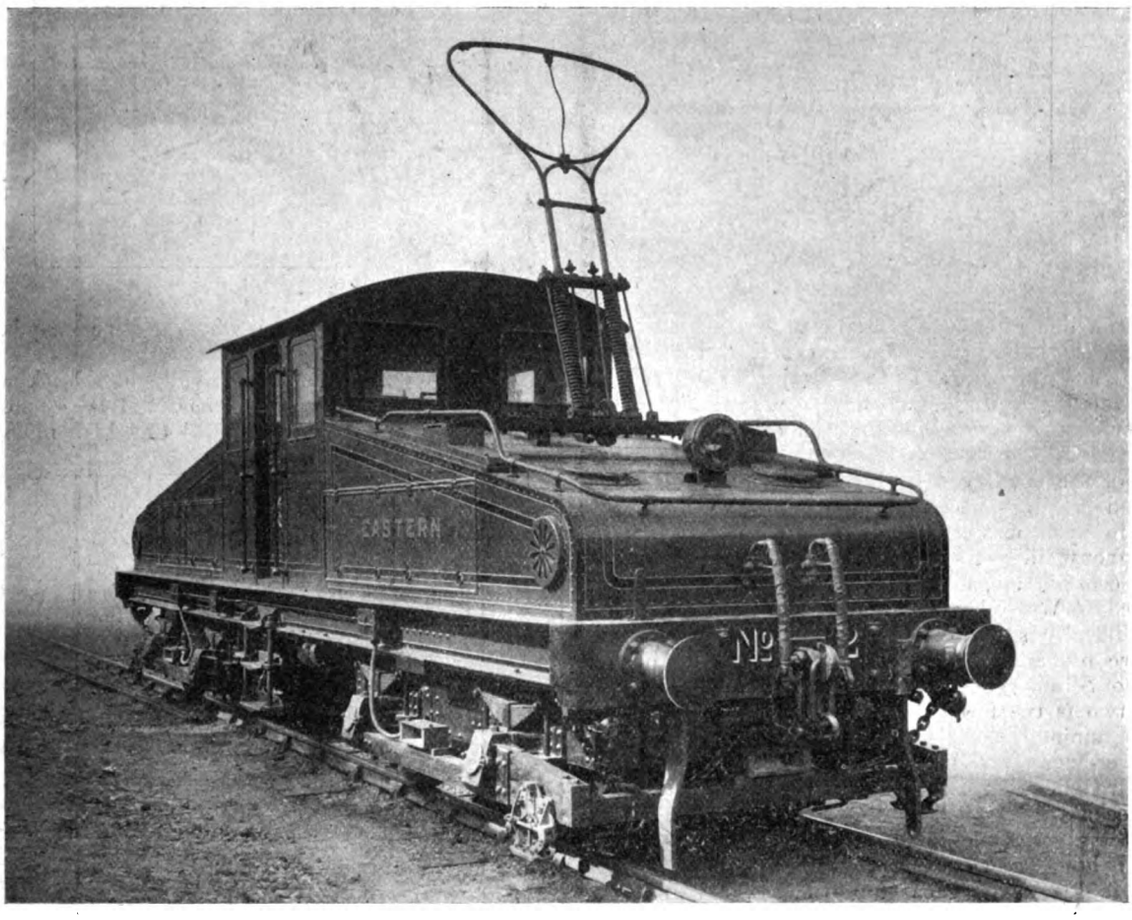
Digitized by Google

side, of ash, glazed at the top and panelled at the bottom, bearing on the outside the arms of the company in transfer. The doorways are 2ft. 4in. wide and 6ft. in the clear. At the ends of the cab are two windows arranged to slide transversely. Arrangements are made for driving the locomotive from each end of the cab, and it is therefore fitted complete in duplicate with master controller, air brake, sand and whistle valves. In the centre of the cab is fitted a cast-iron column to carry the hand brake gear; on each side is a panel for the control and pump circuit accessories, with a main panel at one end for main and control switches, etc. Air gauges and ammeters are also fixed in each driving position. Under the sloping ends are fixed the contactors, reversers, and rheostats; the apparatus for each two-motor equipment being fitted in its own end of the cab, the four-motor equipment being thus split up into two equipments as far as possible as regards location. The contactors are supported from an angle-iron framing built on the floor of the cab, the reversers and resistances being bolted to the floor, but raised above it so that the cable runways may run underneath them. The air brake is of the quick-acting pattern, air being supplied by a B.T.H. electrically-driven compressor of the C P. 14 type, which is hung underneath the frame. This compressor will compress against a pressure of 90lb. per square inch with a cylinder displacement of 20 cubic feet per minute. The air reservoirs are fixed in the ends of the sloping cabs, as also are the sand hoppers, the sand being carried by flexible tubes to the fixed pipes on the trucks, the air operating pipes being connected to the same at the base of the hoppers.

The lighting is effected by a shaded lamp fixed in each driving corner, with three lights in each of the sloping ends and a headlight on each end. All lamps are of 32 c.p., and are arranged for working six in series on a 600-volt circuit. Two portable lights are also provided.

As the locomotives have to operate over sections fitted both with overhead line and third rail, a sliding bow trolley has been provided of special design, automatically reversing itself according to the direction of travel of the locomotive, and also capable of being reversed and lowered when not in use from the cab by a hand-wheel actuating a worm and wheel device. All the cables used are asbestos-covered, and are run either in wood troughing lined with uralite or in steel tubing. Besides being fitted with the nine-wire coupler at each end for the control circuit, 'bus or main-line and pump-line couplers are also provided, so that two locomotives can be coupled together if necessary, and operated by one man for dealing with heavier loads.

The more extended trials in daily work of these locomotives will afford most valuable information to other railway companies contemplating the electrification of their lines.



End View of the Locomotive, showing the Slippers for Collecting Current from the Third Rails, and also the Bow Trolley.

THE LACKAWANNA AND WYOMING VALLEY RAILWAY.

At the present time, when schemes for railway electrification are rife all over the country, the doings of others in this respect become of more than ordinary interest, particularly when they are surrounded by adverse conditions such as are not usually met with. The recently completed third-rail line of the Lackawanna and Wyoming Valley Rapid Transit Company is one that has been carried out under conditions of competition that are certainly above the average. No less than five steam lines are in operation between the cities of Scranton and Wilkesbarre, the termini of the new electric line, and yet so immensely superior has electric passenger and goods traction proved itself that, although the opening of the main section only took place in December, 1903, results have already been obtained that fully justify what would appear at first sight a decidedly risky project.

The two cities of Scranton and Wilkesbarre are situated in a thickly-populated mining district of Pennsylvania, about 20 miles apart, and their population is respectively 150,000 and 75,000, suburbs included. In the immediate territory are several thriving cities, town, and villages, varying in size from Pittston, with 25,000, and Carbondale, with 15,500 inhabitants, down to some with a popu'ation

Digitized by Google

of from 7,000 to 1,000, all more or less dependent upon the two larger cities for commerce and pleasure. The steam main lines running between Scranton and Wilkesbarre had given little attention to the commercial needs of these intervening places, excepting so far as the mining interests were concerned, and did not touch at them; so for this reason an electric line intersecting all the mining towns of any importance and passing through the centre of Pittston, the principal city, became a feasible project. The essential idea of the line is to provide a high-speed service, and as it was evident that more than the usual amount of difficulty would have to be encountered consequent upon the rugged nature of the country and the great number of railway and road crossings necessary, owing to their large experience in such matters, arrangements were made with Westinghouse interests to carry on the work, and the design, construction, and equipment of the property was entrusted to Westinghouse, Church, Kerr, and Co. With much difficulty suitable rights-of-way were obtained, and extensive properties secured for termini in the business centres of Scranton and Wilkesbarre. The more important of the two is the former, which covers about 98 acres of land, containing the passenger station, the goods station, the power-house, and the car-sheds and repair shop, all built of red brick with sills, lintels, etc., of moulded concrete blocks.

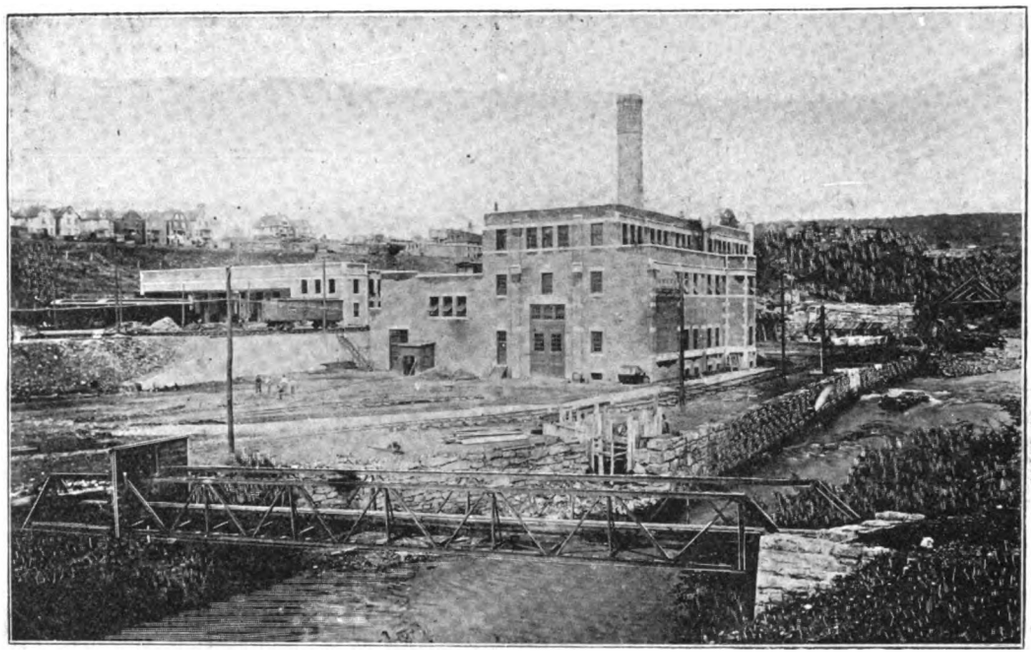


FIG. 1.—Power House, Lackawanna and Wyoming Valley Railway.

The passenger station is E-shaped, 83ft. long and 27ft. deep. It has a basement and two storeys, and is arranged with 11ft. loggias on each side, which provide covered passage-ways from the street to the platform in the rear. The waiting-rooms are well found, with mosaic floors and dark oak panelling, and the whole building is amply lighted electrically. The goods station, placed about 30ft. away from the passenger station, is one storey high and of rectangular shape, measuring 100ft. by 50ft., with an office extension at one end. The whole construction is upon the lines of heavy mill work, and is so designed as to afford every facility for the rapid handling of freight of all descriptions.

The car-house, situated at one extreme end of the yard, has a frontage of 146ft., a depth of 177ft. and a height of 28ft. 6in. clear. It is divided into three bays by brick walls running the entire length of the building; and each bay contains three tracks, each of which can accommodate three cars. While all can be used for the storage of cars, two are designed for that purpose exclusively, and the third is provided with all arrangements to facilitate repairs, which are accomplished in a specially-equipped extension. This latter bay is provided with two 15-ton travelling cranes and a compressed-air supply for operating pneumatic tools and for cleaning purposes. The repair shop runs the full length of the building, and is divided into a blacksmiths' shop, a machine shop, an armature repair room, and oil, sand, salt, and tool rooms. Contiguous are sundry offices, waiting-rooms, and lavatories, and the whole building, which is thoroughly fireproof, is lighted by electricity and heated by hot water, both furnished from the adjacent power-house. Close by in a private street are six small houses for motormen or other employés whose presence may be needed promptly in case of emergency.

The power-house (Fig. 1) is divided by a brick wall into separate boiler and engine rooms, and is rectangular in shape, 90ft. wide, 133ft. deep, and 42ft. high in the clear.

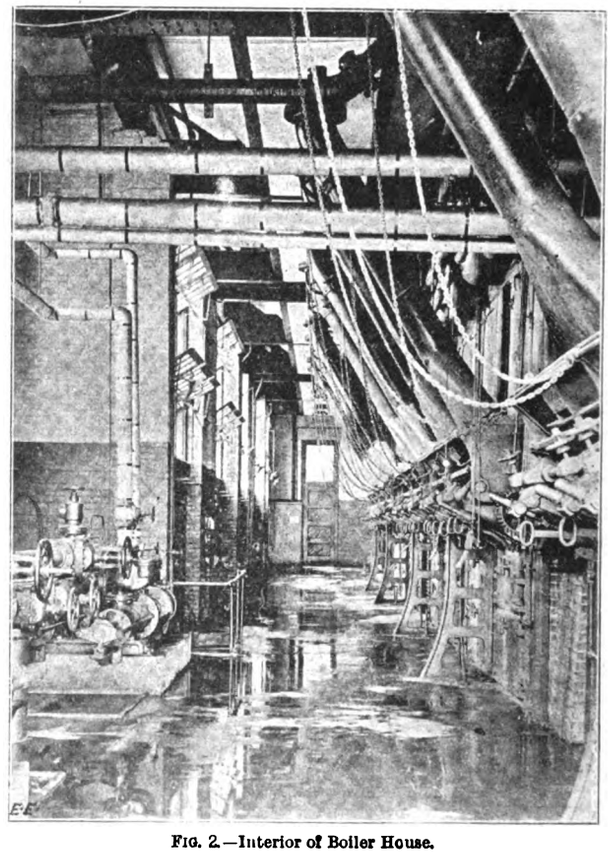

FIG. 2.—Interior of Boiler House.

It has been designed in every detail to allow of easy and cheap extension. The boiler-room (Fig. 2) is arranged to accommodate seven 400-h.p. water-tube boilers of the Babcock and Wilcox type, five of which are already installed. Each is equipped with a Roney mechanical stoker, specially adapted to burn with minimum labour the

Digitized by Google

various grades of coal which the locality provides. Coaling is effected by trucks running on a trestle-supported track at the side of the building, and falling through chutes into a conveyor, the coal is automatically distributed into the bunkers above the boilers. From here it falls, as usual, by gravity into the stoker hoppers, the quantity being controlled by gates. The ashes are collected by a truck running on a track underneath the boilers, being directed into it by hoppers.

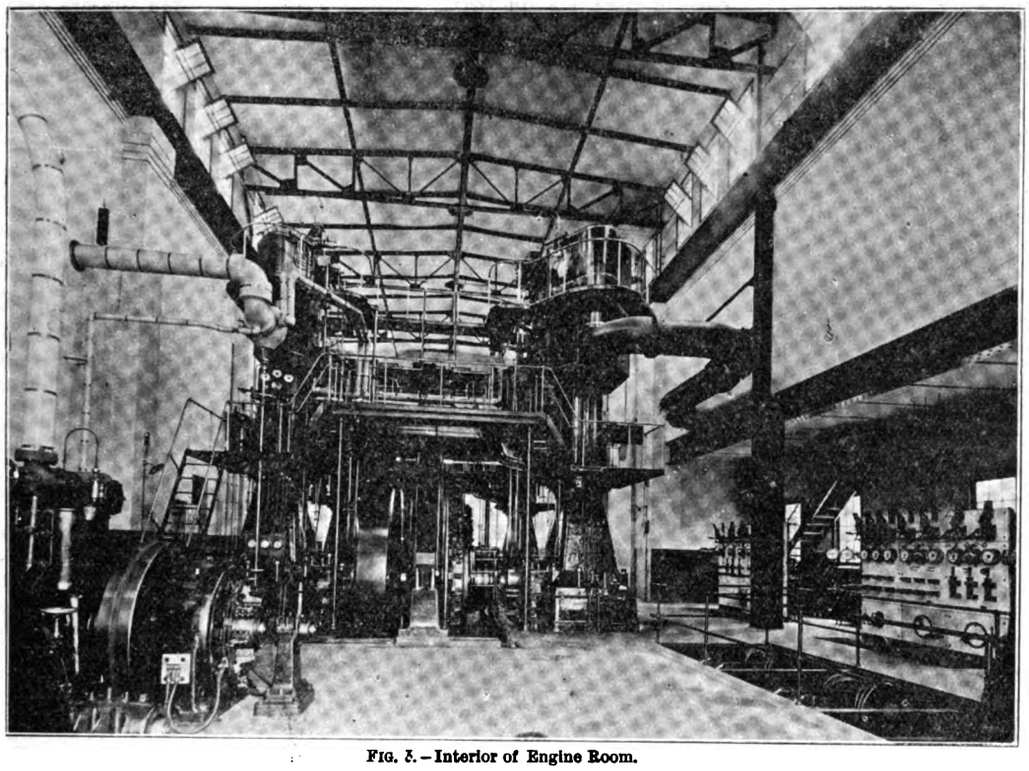

FIG. 3.—Interior of Engine Room.

by the blast from two blowers installed in the basement. The boiler-room auxiliary plant consists of two Worthington compound pumps connected in duplicate to several sources besides the hot-well. From whichever of these the feed is taken, it is passed through a specially designed horizontal, closed feed-water heater, where it attains a suitable temperature.

The steam-piping throughout is of standard full weight wrought-iron pipe fitted with extra heavy flanges, standard gate valves with outside yoke and screw, and covered with the best magnesia compound. It is arranged in a system of interconnected manifolds, with valves so placed as to make isolation of any part for repairs possible without interfering with the running of the plant. Draining is automatically effected by the Holly gravity return system,

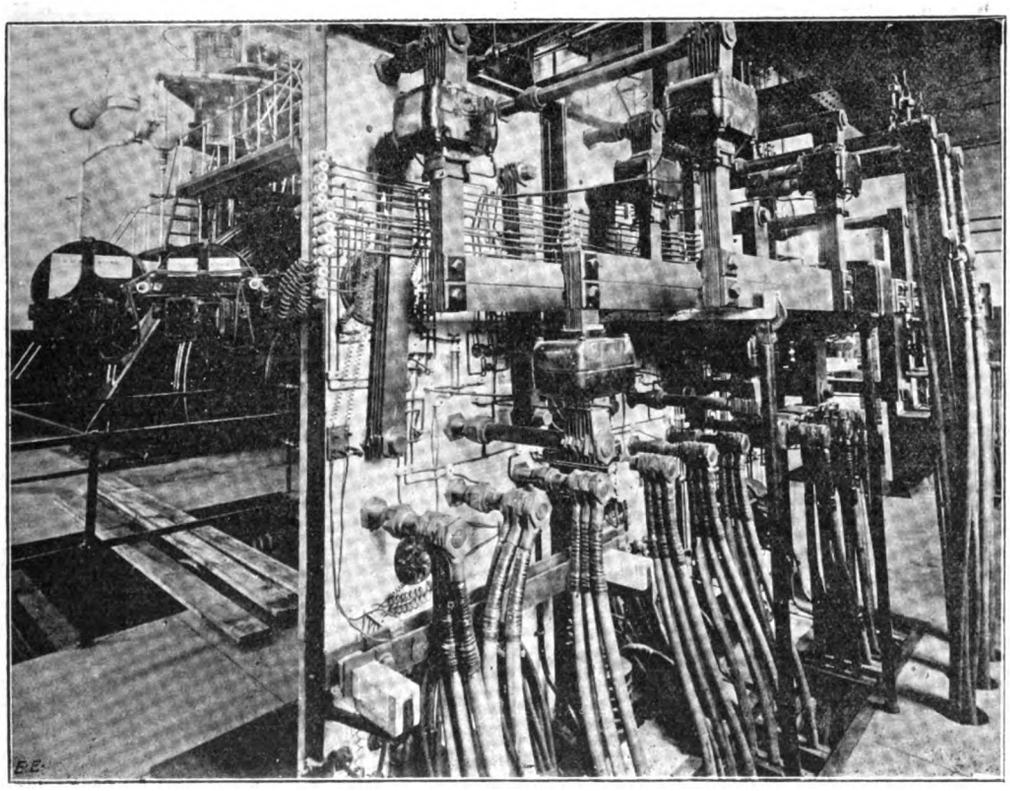

FIG. 4.—Back of Alternating-Current Switchboard.

The chimney is of the well-known Alphons Custodis construction, and is 118ft. high, 9ft. 10in. internal diameter, and rests on a concrete foundation. Access to its interior is possible through a door in its base, and an iron ladder runs from the ground to the top, both inside and out. Its draught may be supplemented, if necessary,

Digitized by Google

and the wastefulness of steam-traps and their accompanying pipework thus avoided.

Coming now to the engine-room, an interior view of which is shown in Fig. 3, the two main engines already installed will, when occasion arises, be supplemented by a third, the bed for which is already in. Each of the present engines is of the Westinghouse vertical cross-compound type, with Corliss valve gear, and when supplied with 160lb. pressure steam and condensing will indicate 2,000 h.p., with a capacity for 60 per cent. overload at higher pressures. The oiling system is entirely automatic, and provides for the collection, filtering, and distribution of the oil. Each engine is coupled to a Westinghouse double-current generator of 1,250 kw. capacity supplying three-phase alternating current with a pressure of 390 volts and direct current at 650 volts. The exciter is at 125 volts pressure, and is derived from independently driven dynamos. A switchboard is provided for each side of the system, the one containing the controlling and measuring gear for the direct-current supply, which is used locally, and the other for the alternating current before its connection with the step-up transformers, where it is raised to a pressure of 22,000 volts and sent out to the line. There is no wood-work in connection with these switchboards, the whole being of marble, 3in. thick, set in steel. Fig. 4 shows the arrangement at the back of the alternating-current switch-board.

The high-tension transmission line is carried on 30ft. to 35ft. cedar poles spaced 100ft. apart, and consists of three No. 4 B. & S. hard-drawn bare copper wires arranged in a triangular manner and supported on umbrella type glass insulators. It is 14 miles in length, the far end being taken to the sub-station at Hancock, where the current is transformed and converted into direct. This is carried out in a fireproof room and tower separate from the main buildings, which are equipped for passenger and goods service along very similar lines as the main stations.

Between Scranton and Wilkesbarre the permanent way is double tracked, with cross-overs, and is carried out in the heaviest class of construction. The rails are of 90lb. A.S.C.E. section, fixed to 7ft. by 8in. long leaf yellow-pine sleepers, spaced 2,640 to the mile, which in turn are bedded on ballast and broken stone of a minimum depth of 10in. Under the fishplates two 4/0 protected bonds are placed, and every 500ft. the track is cross-connected by bonds of 250,000cm. The third rail, of 75lb. A.S.C.E. section, is placed in the centre of the track, and is bonded with two 400,000cm. foot bonds. It is broken at the stations, approach blocks being provided to make and break the circuit, and continuity is maintained by the aid of two 300,000cm. cables run underground on the solid system. The whole right-of-way, which varies from 60ft. to 150ft. in width, is protected by a wire fence. Speed being the primary consideration, much trouble has been taken to make the line as straight and level as possible with the result that there is only one 12-degree curve, and one grade greater than 1½ in 100. The natural and artificial difficulties of the country, as stated, have been very great, in places necessitating long cuttings through hard material, largely solid rock. One case that occurred at Pittston, where there is a 1,000ft. cutting, 25ft. deep, through rock and hard pan, is typical of these difficulties; and here, in addition, the Erie Railway had to be maintained in operation on one side, and a road carried across by means of a temporary bridge, while the water from two collieries and one washery, and the surface drainage from a very large area, had to be diverted by means of timber flumes. Such difficulties have almost proved the rule more than the exception, and might be extended into a formidable list. Roads, railways, and houses have been moved, in some cases considerable distances, and bridges and viaducts have been necessitated in great numbers. Of these, the one at the approach to Wilkesbarre, a viaduct 554ft. in length, has embraced the greatest engineering difficulties, as at this point the line is carried over the road, the Wilkesbarre Traction Company's

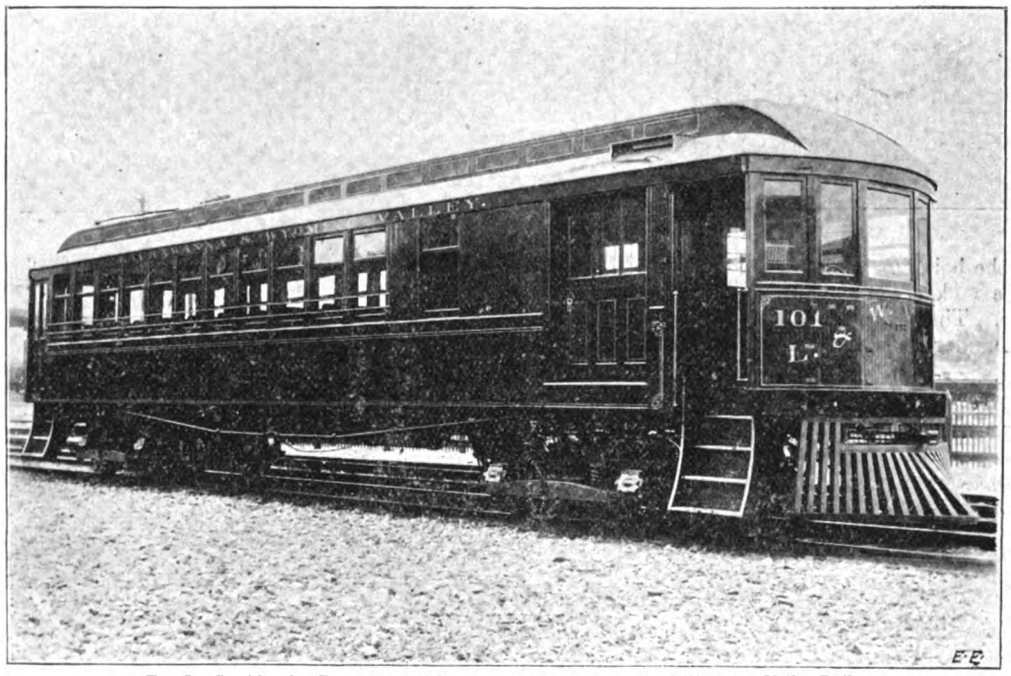

FIG. 5.—Combination Passenger and Baggage Car. Lackawanna and Wyoming Valley Railway.

trolley line, several tracks of the Lehigh Valley Railway, and the Central Railroad of New Jersey. The road and the tramcar line have been moved 30ft., and an embankment has been built across the old highway to bring the line to the viaduct. The Wilkesbarre terminus is the southern extremity of the line, and, as in the case of Scranton, provides ample accommodation for both passenger and goods traffic.

The rolling-stock comprises 10 regular passenger cars, three combination passenger and luggage cars (Fig. 5), four freight cars, and one for construction and repair work. They are all of the same dimensions, 42ft. long over end panels and 52ft. over platform, and were built by the American Car and Foundry Company to special designs. The trucks were made at the Baldwin Locomotive Works, and are of the M.C.B. swing-motion equalised bolster type; the motors are 150 h.p. of the single-reduction Westinghouse make, being attached to the rear truck by the aid of Gibbs cradle suspension. The passenger cars contain seating accommodation for 59, and are divided up into two compartments, one being for smokers. As the cars traverse loops at each terminus there is only one motorman's cab, and the backs of the seats are stationary. The construction and repair car has movable sides, and is equipped with two single-reduction 75-h.p. Westinghouse motors, which will enable it to make fast runs in emergency and perform

Digitized by Google

snow-plough and other heavy work. In addition to this there is a 50-ton steam locomotive, that is looked upon as a stand-by in the event of a serious failure of the current. All cars are fitted with trolley poles for use in the yards, and Westinghouse automatic air-brakes are installed, as well as vertical hand-wheel brakes. The wheels are in all cases cast steel, with steel tyres and axles, except the construction car, which has chilled cast-iron wheels. At present a 20-minute schedule of running trains is inaugurated, which will be shortened as rapidly as the passenger traffic may demand.

We are indebted to the Westinghouse Company for the above particulars.

NOTES ON MOTOR-STARTING SWITCHES.

[CONTRIBUTED.]

(Continued from page 593.)

The solenoid-control switch is an extension of this pattern, but with more perfect automatic action. This type of switch is shown in Fig. 4. This figure shows a slate on which are mounted a large solenoid switch, above this the ordinary multiple-step switch, the lever of which is connected at one end to a plunger which works in a dash-pot, while the centre is connected to a plunger of a second solenoid. Down the right-hand side are also shown a number of subsidiary solenoid switches. The method of working this switch is very simple, and the whole arrangements are carried out so as to attain a perfectly automatic reliable switch. The main solenoid is wound with many turns of fine wire, and this is energised by a current taken from the mains and controlled by a small tumbler switch capable of dealing, say, with one ampere. As soon as the circuit is made through the main solenoid switch by closing the tumbler switch, the switch is closed and the current is supplied to the shunt of the motor, and also to the armature through the whole of the external armature resistance, which is mounted at the back of the slate, the main solenoid switch acting as the main switch for the motor, although in the complete equipment a double-pole main switch ought also to be included. Upon closing this main switch a small current is supplied to the upper solenoid, and the plunger is attracted and so rises slowly upwards. The speed at which the plunger, and consequently the contact lever, moves is regulated by the dash-pot in two ways; in the first place, the viscosity of the fluid in the dash-pot can be varied, and, in the second, the end of the plunger forms a small piston, in which there is an opening to allow the fluid to escape from one side of the piston to the other. The size of this opening can be altered at will, and, of course, the speed of the lever will increase as the opening is made larger. For each individual switch the correct speed is found, and is usually set once for all; but if it is necessary to alter this, it can be done, only as the dashpot has to be opened out and the piston removed, there is little fear of the switch being tampered with by any than authorised persons. When the lever has risen to the second contact, the top smaller solenoid is energised, and its switch closed. This acts in exactly the same manner as the switches in the starter just described, and opens a path to the armature through a shorter length of resistance. The contact lever now moves on to the third contact, and the second auxiliary solenoid is energised, and the connected switch closes, a further amount of resistance being cut out. There is no difference between this solenoid switch and the previous one, except that whereas in the former case, when all the switches were closed, all the various lengths of resistance were connected with the armature circuit through any switch. In this case, as soon as the second solenoid is closed, the circuit is opened through the first auxiliary solenoid, and this becomes demagnetised, and the switch it controls at once opens, so that the only path through the armature is that offered by the last closed solenoid switch. When the final auxiliary solenoid switch, generally known as the master switch, is closed, the armature is directly connected across the mains.

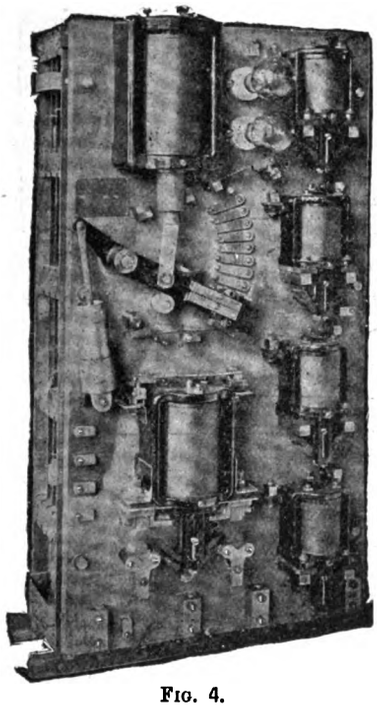

FIG. 4.

The Sturtevant Engineering Company, Limited, who are the makers of this switch, have fully considered all the possible points of improvements; it will be noted that only a small shunted current sufficient to energise the various solenoids is dealt with at the contacts, so that very little arcing or burning will occur here. Again, during the operation of starting the motor this current has to energise the various solenoids, and therefore has work to do, but when the motor is under weigh all that the shunted current has to do is to keep the main and master solenoidal switches closed, and for this a smaller current will suffice. This result is attained by arranging two or three lamps in series in such a manner that the circuit is only closed through them when the master switch is closed. Again, the makers acknowledge the importance of dealing with the current due to the self-induction of the shunt, and consequently additional lamps are inserted so as to be in circuit at the periods of make and break. In starting the motor through this switch the lamps are seen to incandesce, and the main switch closes, then the lever gradually moves upwards the various auxiliary solenoidal switches, closing and opening again in rotation. When the motor is stopped the lever gradually drops down to the off position, and as it leaves the last contact breaking the shunt connection the lamps will be seen to momentarily incandesce to a great degree, showing the high value of the induced E.M.F. The auxiliary small switch required to energise the main solenoid need not be placed on the switch base, but can, and is generally, placed some distance away near the machine driven by the motor. In the case of the failure of the current, the main and master solenoids will become de-energised, and their switches will then open. It is impossible to then again start the motor until the contact lever has descended to its off position, so that the solenoids themselves act as a most efficient no-volt release. It is not customary to make this piece of apparatus complete with an overload preventer. If this is required, it should be in the form of a secondary piece of apparatus—viz., a maximum type circuit breaker.

The switch described above is for larger sizes of motors. For the smaller sizes the switch consists of the main solenoidal-controlled switch and the solenoidal-controlled contact lever fitted with the necessary steps. All the auxiliary solenoids are then omitted, and the main current is dealt with at the multiple-step switch in the more ordinary manner. For large sizes it is better to deal here only with the shunted current necessary to energise the auxiliary solenoids.

A simple form of switch is shown in Fig. 5 This switch was designed by Mr. Gibbings when chief electrical engineer at Bradford. This town is one where there are a very large number of motors let out by the Corporation on hire, and Mr. Gibbings found that a very large percentage

Digitized by Google

of the breakdowns to motors which occurred in the town were due solely to defective starting switches, and he therefore set to work to design a switch which should answer ordinary requirements, be simple in its action, and low in cost. The switch is now made by Mr. Bertram Thomas, of Manchester, and consists of the ordinary movable lever and multiple steps, but the lever is moved by compressed air. The lever is connected to a plunger which works in an air-cylinder. The operator presses the handle inwards, and turns it so as to lock it on to the lever. This also releases a spring, which causes the lever to move over the contacts at a fixed speed, the actual rate being controlled by the amount of air which is allowed to escape. The air opening being adjustable, when the opening is completely closed the lever will retain its position for long periods, thus showing the good fit which the piston makes in the cylinder. The switch is also fitted with a no-volt release and automatic overload preventer. Recently the makers have further improved the switch by arranging for quick break between the different contacts, and they thus minimise to a great extent all sparking and burning.

There are several good makes of ratchet-type switches, and in Fig. 6 is shown the ratchet attachment of the switch made by Bray, Markham, and Reiss. This attachment is mounted at the back of the slate, the corresponding position at the front being occupied by the ordinary multiple switch. The action of starting the motor by this switch is as follows: The operating handle is first moved in one direction, carrying with it a single-pole switch which is held in the on position by means of a trigger which engages with the keeper of the no-load magnet. At the moment of making contact the ratchet wheel and the contact arm will have turned into such a position that the lever is on the first contact. The handle is now turned in the opposite direction until the pawl comes into contact with a tooth; it is impossible to take more than one tooth at a time, as the ratchet wheel is shrouded for a great proportion of its circumference. Stops are shown on the face between which only the handle must be moved; if the operator moves the handle beyond these limits, or should he desire to leave some resistance in circuit with the armature, and so leave loose of the handle before all the resistance is cut out, the handle will come back to the off position and a projection on the pawl lever will cause the single-pole switch to open. This is an important point, as it prevents most effectually any portion of the resistance being left in circuit under any circumstance. The switch is fitted with overload and no-volt releases, and also with a magnetic blow-out. As the break always occurs at one point, the single-pole switch, the point of sparking is localised, and the addition of the magnetic blow-out prevents any serious burning occurring.

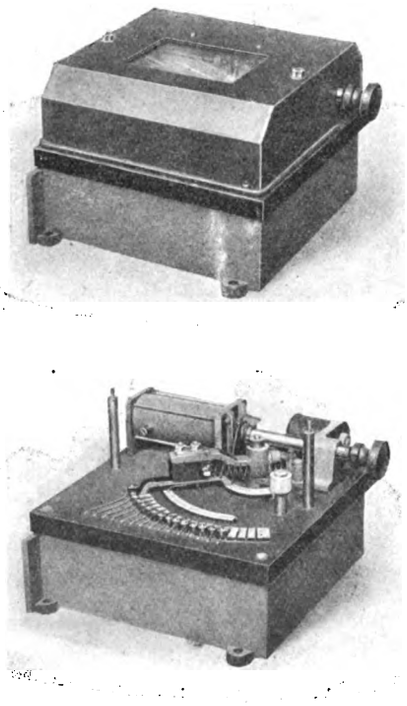

FIG. 5.

Liquid resistance starting switches are of great benefit in many classes of works, especially where the motors and controlling apparatus are exposed to the action of the atmosphere, but with shunt-wound direct-current motors they have the disadvantage that there is yet no good switch on the market which will fulfil all the requirements of the metallic resistance switch. The usual liquid starting switch consists essentially of an iron tank filled partially with an electrolyte, and into which an iron or copper plate is lowered when the motor is started, the resistance being decreased as more and more of the movable plate is immersed; the final contact should be between metal and metal. The one great disadvantage is that the solution cannot be plain water, owing to its low conductivity, and, therefore, an acid or alakaline solution must be used; generally a weak acid solution is chosen. The passage of the current sets up electrolysis, and acid fumes are given off which attack any metal work. The majority of the metal work can be painted with acid-resisting paint, but the points of contact cannot be, and hence there is liability of undue wear here. In the best forms of liquid switches no contacts are made directly over the tank, but rather at the side, and the movable plate is operated by means of worm gear to permit of the motion of the plate being slow.

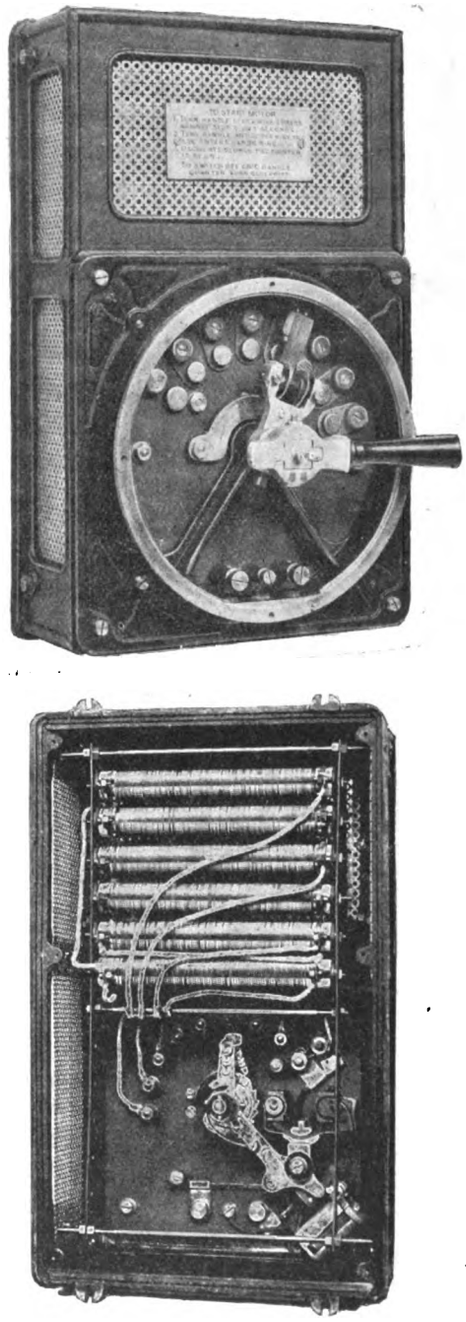

FIG. 6.

Digitized by Google

Owing to the rough treatment which liquid starters will stand, they are of great service, and as they are subjected to usage that the metallic switches could not survive for any length of time, the corrosive action of the acid fumes is only a minor matter. When this type of starting switch is used, it should be in conjunction with the maximum and no-volt circuit breakers before mentioned. These circuit breakers, though of delicate construction, can be mounted in iron boxes and made perfectly watertight, the handle for setting them should they open coming through the sides of the cases, and they will, therefore, be protected against much rough usage; in addition to which these necessary parts of the equipment need not be fixed in such exposed positions as the starting switches themselves, but may be placed some little distance from the motor under cover. The writer lately examined some electrical plant at one of the large shipyards where liquid starters were used, each motor being further supplied with maximum and no-volt circuit breakers mounted in iron cases, and he found that the arrangement worked very satisfactorily, and that there had not been the slightest trouble with any of the plant since erection, although at a neighbouring yard, where only liquid switches were used without circuit breakers, the fields being directly connected across the mains in the more ordinary manner, the breakdowns to the motors are far from being uncommon.

(To be continued.)

NOTE ON A SUGGESTED NEW SOURCE OF ALUMINIUM.*

BY BUENA POOL, B.SC.

In bringing the following results before British electrochemists, I should like at once to point out that they are to be found in full detail in the *Geological Magazine* for 1903 in the work of Mr. Holland and Messrs. Warth. The suggestion particularly to be brought out by this paper is the practical utilisation of the results. As is well known, practically all the aluminium produced at the present day is made from bauxite, of which the British Isles possesses but scanty deposits. It appears, however, that in India we possess a vast treasure-house and store of aluminium in a formation which is spread over the surface of thousands of square miles of country waiting for the spade of the prospector. The laterite deposits of India have long been a puzzle to geologists. They occur spread over vast areas as a purely superficial deposit of depths varying from a few feet to a few hundreds of feet, chiefly over the Deccan trap area of Central India. Until recently laterite, in consequence of its appearance and consistency, was loosely classed as a clay; recent careful investigations and analyses seem to show, however, that it is much more closely analogous to bauxite, the aluminium being present in the hydrated form and not as silicate.

Laterites vary pretty considerably in composition; they fall naturally into two groups—the "high-level" and the "low-level" laterites High-level laterites, as the name indicates, are found at higher elevations on the Deccan traps of Central India; the low-level laterites, on the other hand, are found along the coasts. The western coast-line of India, from Ratnigiri southwards, consists of a laterite formation up to the thickness of 200ft., and on the eastern coast-line laterite occurs everywhere. But this is a much less massive formation than the rock of the western coast, being at most only about 20ft. thick. Low-level laterites differ from the high-level laterites of the interior in structure and composition; they are less hydrous and more concretionary; they contain more silica in rounded grains and less alumina. They are apparently detrital in origin, being formed by water action from the high-level laterites Drs. H. and F. J. Warth† have made a series of analyses of Indian laterites. They find that in chemical composition Indian laterites fall into four distinct classes:

I. The deposit found at Kodikanal, which stands alone. It is a pure gibbsite ($Al_2O_3 + 3H_2O$); after ignition it contains nearly 95 per cent. of aluminium oxide. It forms a deposit of 1ft. in thickness, consisting of loose crusts and plates, over an area of at least several acres, lying between the surface soil and the charnockite rocks. Kodikanal is a small summer resort on the Palni Hills in the Madura district of the Madras Presidency (lat. 10° 13′ 21″; long. 77° 31′ 38″ E).

II. Laterites (from districts which are not specified) with pisolitic structure; they are bauxites, very rich in alumina, and with very little iron, closely resembling wocheinite. Analyses of four specimens are given in Table A.

TABLE A.

—	2·23	2·11	2·75	2·67

They contain little iron, very little silica, and a rather large amount of titanium dioxide, probably as ilmenite.

III. The third group includes specimens such as have usually been called high-level laterites. These are practically bauxites which have been formed from highly ferruginous igneous rocks; they belong mostly to the area of the Deccan traps. It is found that the amount of iron in the laterite bears a close relationship to the amount in the underlying rock. This bears out the theory that they are derived from them. Analyses of six such specimens are given in Table B; with the exception of two specimens with admixed quartz sand they show very little silica. The resemblance of these analyses to those of ordinary bauxite is obvious and striking. A general property of these high-level laterites is their infusibility before the blow-pipe. This serves to distinguish them from the low-level or detrital laterites forming the next group.

IV. Low-level laterites. Free silica, and probably an even larger amount of clay, is present in all cases. Analyses of eight specimens from different localities are given in Table C. These analyses show that the amount of alumina in low-level laterites may vary from about 30 per cent. down to zero. The amount of free quartz also varies irregularly from about 40 per cent. to 4 or 5 per cent., depending on the locality, and clay (as kaolin) from 17·16 to 50·26 per cent. These laterites, as a rule, contain more iron than the high-level deposits; in places the iron content is so great that the laterite has been used by the natives as a source of iron. This effect is probably due to the sorting action of running water, which has floated away the lighter scales of gibbsite from the original high-level laterite, and so caused a relative increase of the heavier iron ore.

Mr. T. H. Holland,* director of the Geological Survey of India, has pointed out that this deposit only occurs in countries with tropical climate and an abundance of running

water. (The latter suggests the possibility of water power for the generation of the electricity necessary to work the ore.) Where precipitation is low, although the climate may be moist, a material known as "kunkar," is found, which, though otherwise similar to laterite, contains a great deal of lime. Laterite is apparently "kunkar" out of which the lime has been abstracted by the solvent action of running water. The colour of laterite varies according to the particular iron hydrate present; its consistency *in situ* is like putty. On exposure to the air, however, it hardens, owing to spontaneous dehydration, and becomes darker in colour as the ferric hydrate loses water. It is a very porous rock, being frequently traversed by cracks and small irregular tortuous tubes; in consequence of this it makes very poor and barren soil. Low-level laterites show no structure, but the high-level ones have a marked tendency towards a concretionary structure, while higher still the soft material often retains a perfect cast of the igneous rock from which it is formed. The junction of the laterite with the unchanged rock is sharp, sudden, and complete. Arguing from this and from its distribution and other characteristics Mr. Holland suggests that laterite may owe its origin to some bacterial agency which forms it *in situ* by attacking the silicates in igneous rocks. It would thus, by absorbing the silica and rendering it soluble, leave the iron and aluminium, which would become hydrated and left as the bauxite-like deposit which we find. This bauxite has all the characteristics to render it commercially valuable; its pureness, ready accessibility, widespread occurrence at all elevations, and association with flowing water point it out as an almost perfect source of aluminium.

VOLTAGE RISES ON THREE-PHASE CIRCUITS.*

It is well known that in single-phase installations employing concentric cables, incorrect switching in or out, or even the blowing of fuses, often causes a breakdown between the outer conductor and the lead covering. From tests made in connection with this matter, the rule "outer conductor to be switched in first and inner conductor to be switched out first" has resulted. In the case of three-phase installations also excessive voltage rises and the consequent breakdown of cables or machines may result if one phase, in a circuit consisting of the generator, the cable, and transformers on open circuit, is opened at the generator end and one of the other two phases at the transformer end. This arrangement is shown diagrammatically in Fig. 1. The generator with its terminals I., II., and III. is shown on the left, and the open-circuit transformer terminals, 1, 2, and 3, on the right. The cable lying between the two may be represented by the three capacities, C_1, C_2, and C_3. The switches or fuses are shown at *a*, *b*, *c*, *d*, *e*, *f*, and *b* is assumed to be open at the generator end, and *d* at the transformer end. The opening of *b* and *d* may in practice occur either through carelessness or through the blowing of fuses. With the conditions stated, the following circuit exists: from I., through *a*, the capacity C_2, *e*, the open-circuit transformer, 3—2, *f* and *c*, back to the generator terminal II. At the same time, the capacity C_3 is connected in parallel with the generator, and the capacity C_1 in parallel with the transformer. The arrangement is shown more simply in Fig. 2, and it will be seen that all the conditions for a resonance effect are present.

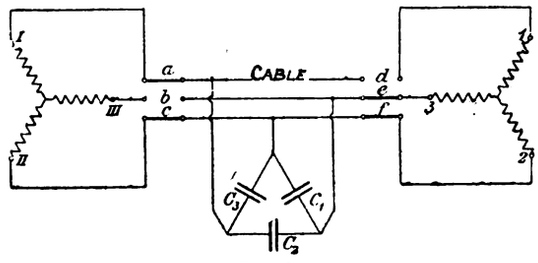

FIG 1.

Experiments were made in the laboratory of Messrs Felten and Guilleaume on an artificial circuit of this sort, composed of three mica condensers, $C_1 = C_2 = C_3 = 1$ microfarad, and an iron-cored choking coil having an ohmic

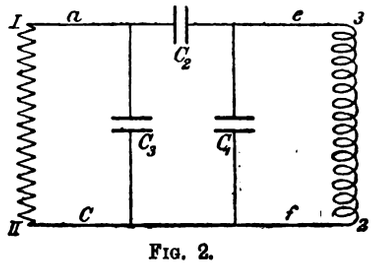

FIG. 2.

resistance of 164 ohms and an impedance of 1,310 ohms at 61 ∼ (coefficient of self-induction = 3·4 henrys), as determined by current, voltage, and watt measurements with a sine wave of E.M.F. With a generator voltage of 14 volts at 61 ∼ the following voltages across the several condensers were measured:

Across condenser $C_1 = 120$ volts.
" " $C_2 = 126$ volts.
" " $C_3 = 14$ volts.

These voltages were measured on an electrostatic voltmeter having negligible capacity compared with one microfarad. The self-induction of the generator was also negligible. It will be seen that condenser C_2 (or the cable) was subjected to a pressure nine times as great as that at

* Abridged translation of an article by P. Humann in *Elektrotechnische Zeitschrift*, Oct. 13, 1904.

Digitized by Google

the generator terminals, which in practice might lead to disastrous results. The calculated capacity for complete resonance with the above self-induction at 61 ⁓ is two microfarads. An actual measurement was made with the choking coil connected simply in series with a condenser of two microfarads, and complete resonance was obtained, the voltage across the condenser being 126 again with 14 volts at the generator terminals.

At the first glance it is not quite clear why the connection of a one-microfarad condenser in series with a combination consisting of a choking coil of 3·4 henry and a condenser of one microfard, as shown in Fig. 2, should give resonance, when by calculation a condenser of one microfarad corresponds to a self-induction of 6·8 henrys for complete resonance at 61 ⁓. Considering the above combination of self-induction and capacity as simply an equivalent self-induction, however, its value works out at

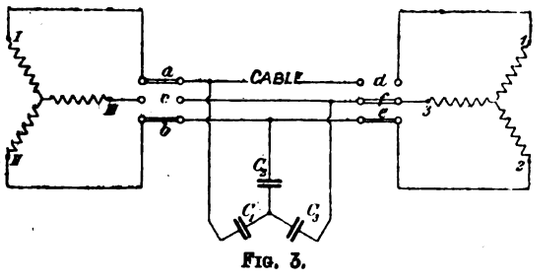

FIG. 3.

7·1 henrys from current voltage and watt measurements, which showed that impedance = 2,760 ohms, resistance = 438 ohms. Allowing for experimental errors, this value of 7·1 is a good check on the calculated value of 6·8. The impedance of 2,760 ohms also checks fairly with the value 2,600 calculated from the expression for the impedance of a parallel-connected choking coil and condenser—viz :

$$\text{Impedance} = \frac{\sqrt{R^2 + w^2 L^2}}{\sqrt{(1 - w^2 L C)^2 + w^2 C^2 R^2}}$$

where R = ohmic resistance;
L = self-induction;
C = capacity;
$w = 2\pi$ ⁓.

The impedance of such a combination, in fact, at first increases as the capacity is increased until the capacity reaches the correct value for current resonance; after that the impedance of the combination falls off as the capacity is further increased.

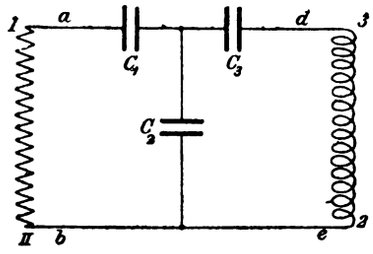

FIG. 4.

The substitution in the above experiment of three mesh-connected condensers for the three cables is not quite allowable, so a second experiment was made with the same three condensers, C_1, C_2, and C_3, of one microfarad each, star connected as shown in Fig. 3 and Fig. 4. The current path in this case is from I. through *a*, C_1, C_3, *f*, 3, 2, *e*, *b*, and back to II. In this way condenser C_3, with the self-induction 2—3, is connected in parallel with the condenser C_2. The self-induction was varied until decided resonance occurred—*i.e.*, until a large voltage increase above the generator voltage occurred across one or the other condenser. The following results were obtained with a generator voltage of 15 :

Voltage across C_1 = 35 volts
" " C_2 = 40 "
" " C_3 = 84 "
" " 3—2 = 128 "

showing nearly a six-fold voltage increase across C_3.

From a test made on the self-induction used above coupled in series with an adjustable condenser, the capacity C which gave complete resonance was obtained, and from this and the fact that for complete resonance $L = \frac{1}{w^2 C}$ the value of L was found to be 10·2 henrys. This value was also confirmed by means of direct measurement of volts and amperes in the self-induction alone at 61 ⁓. The writer shows by the ordinary rules for capacities and inductances in combination, neglecting ohmic resistance, that with L = 10·2 and $C_3 = 1$ the effective self-induction of the branch in Fig. 4 containing C_3 and 3—2 is 3·38 henrys. This branch is in parallel with $C_2 = 1$, and the effective self-induction of the whole is 6·72 henrys. This combination can now be considered as a simple self-induction of 6·72 henrys in series with a condenser C_1 of one microfarad. The theoretical value of the inductance to give resonance in series with a one-microfarad condenser at 61 ⁓ is $L = \frac{1}{w^2 C} = \frac{10^6}{w^2 \times 1}$ = about 6·8 henrys, which is a very good check on the above value of 6·72 calculated from the measured self-induction and capacities.

The above results show clearly that with either method of representing the capacities of three-phase cables, very considerable voltage rises may occur if one phase is opened at the generator end and another phase at the transformer end. As a safeguard high-voltage safety devices should always be installed, but care must be taken that they do not operate with too great a current, as otherwise the safety device itself may produce an excessive voltage rise. A resistance should be connected in series with the spark-gap. Further, it would perhaps be advisable to avoid fuses altogether in high-tension installations, and to replace them by automatic oil switches which cut all the phases in or out at the same instant.

BITUMEN: ITS CONSUMPTION IN THE UNITED KINGDOM AND ITS PRODUCTION IN TRINIDAD.

BY W. POLLARD DIGBY, F.S.S.

Of the properties of bitumen, either when laid by any paving company for the man in the street to walk on, or buried under the side walk forming an integral part of the insulation of electric light cables, and walked over by the man in the street, it is not necessary to write here. The *Proceedings* of the Faraday Society (*Electro-Chemist and Metallurgist*, vol. iii., pp. 322-335 and 398-401) contain Mr. D. A. Sutherland's paper on "Bitumen in Insulating Compositions," wherein the chemical properties of this singular natural product are discussed. It is now the object of the writer to show the volume and source of the United Kingdom's import of bitumen for the last 15 years.

At the onset one is faced by the question of what constitutes bitumen. Our imports of this nature are classed as "Asphalt or Bitumen." Mr. Sutherland's definition may again be quoted : "Natural bitumen is composed, as far as we have been able to learn, of saturated and unsaturated dicyclic, policyclic, or alicyclic hydro-carbons and their sulphur derivatives, with a small amount of nitrogenous constituents. Bitumen is a natural substance composed of such hydro-carbons and their derivatives, which melts on the application of heat to a viscous liquid; soft bitumen consisting of alicyclic hydro-carbons, which by heating or other natural causes becomes converted into hard bitumen. The line between the classes cannot be sharply drawn." Small wonder that the Board of Trade says, "Oh, asphalt or bitumen! It doesn't matter which you call it. Call it both if you like so far as Customs declarations are concerned."

Natural bitumen actually occurs in commercial quantities in Palestine, Venezula, California, Trinidad, Cuba, Barbadoes, Utah, Wyoming, Montana, Mexico, Peru, Columbia, Canada, and in smaller quantities in France, Italy, and Germany. Also in limestone (asphalt) at several places in Europe—chiefly at Val de Travers in Switzerland, and Limmer in Germany, as well as in the siliceous limestone, in sandstone, and in the shale formations.

But so far as the detailed trade returns of the United Kingdom are concerned, the sources known until 1894 were Germany, Holland, France, Italy, "other foreign countries,"

Digitized by Google

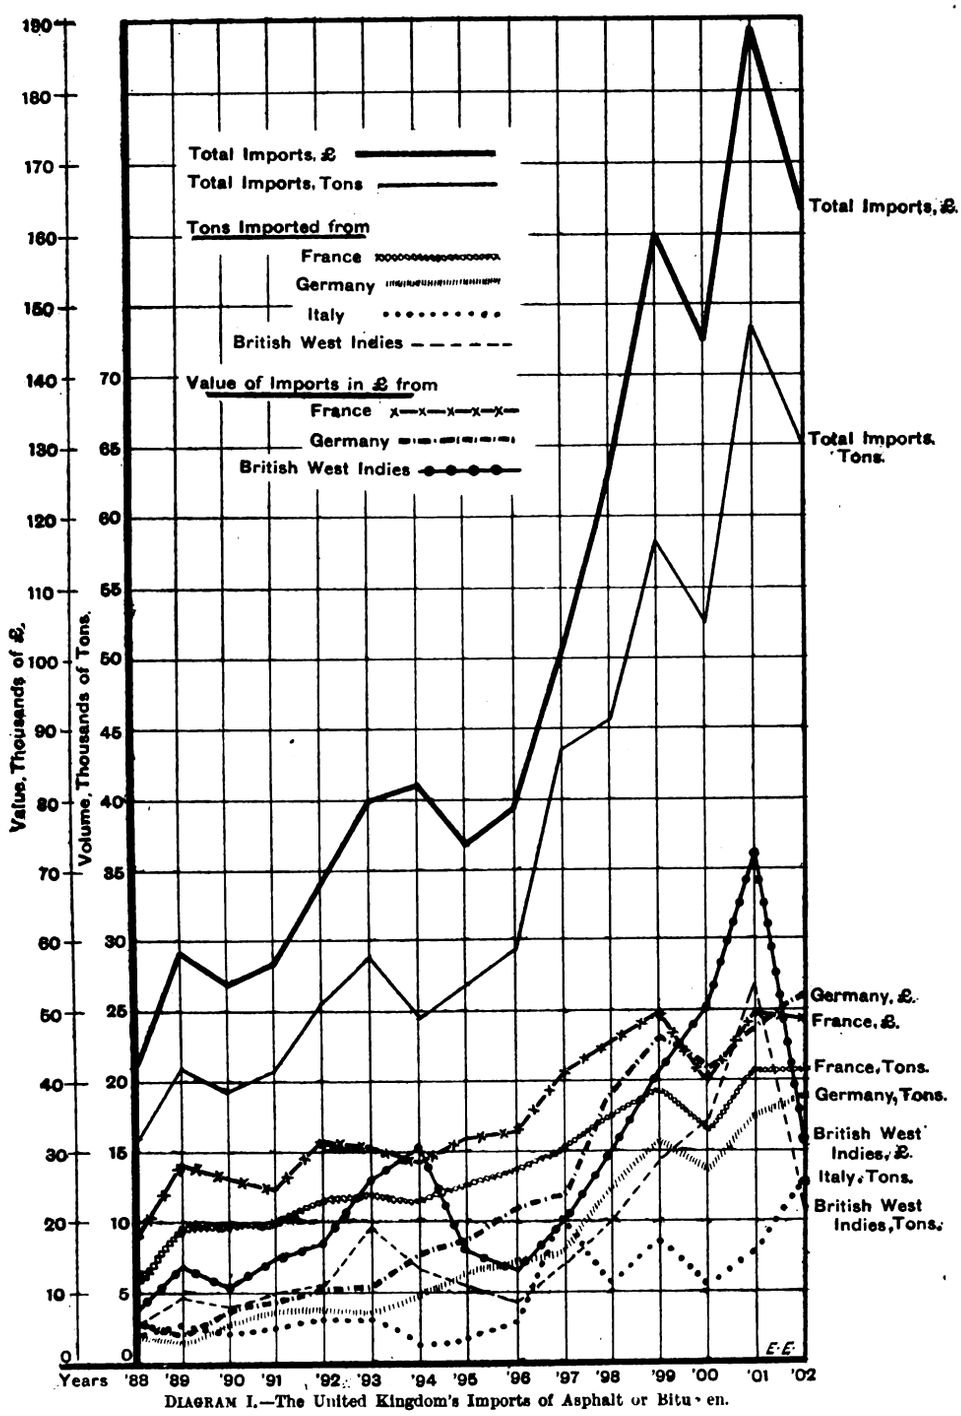

DIAGRAM I.—The United Kingdom's Imports of Asphalt or Bitumen.

and the British West Indies, when Holland disappeared from separate enumeration to reappear later. As the records of the imports from Holland are not continuous, the writer has reckoned it among the "other foreign countries. In Diagram No. 1 the total value and tonnage of the imports in any one of the 15 years enumerated may be seen, as also the tonnage respectively obtained from France, Germany, Italy, and the British West Indies. The value of the imports from France, Germany, and the British West Indies in each year is also shown. The fourfold rise in total tonnage and in total value from 1888 to 1902 is very striking. Of the individual countries, France is still ahead of Germany in tonnage, but since 1900 the respective values have been about equal. The relation between the two totals and the two British West Indies curves is interesting. In 1889 and 1893 a fall in the total values was accompanied by a reduction in the West Indian imports. In 1899 this was not the case, but the fall in the totals of 1901 is entirely due to the falling off in the imports of Colonial produce. As comparisons of individual years are apt to be fallacious, the writer has prepared the accompanying Table A.

The table shows the marked growth of the purchases of "asphalt or bitumen" by the United Kingdom from all sources. Relatively the greatest advance has been from

TABLE A.—Imports of Asphalt or Bitumen into the United Kingdom.

	Annual average for five years ending 1892.		Annual average for five years ending 1897.		Annual average for five years ending 1902.	
	Tons.	£.	Tons.	£.	Tons.	£.

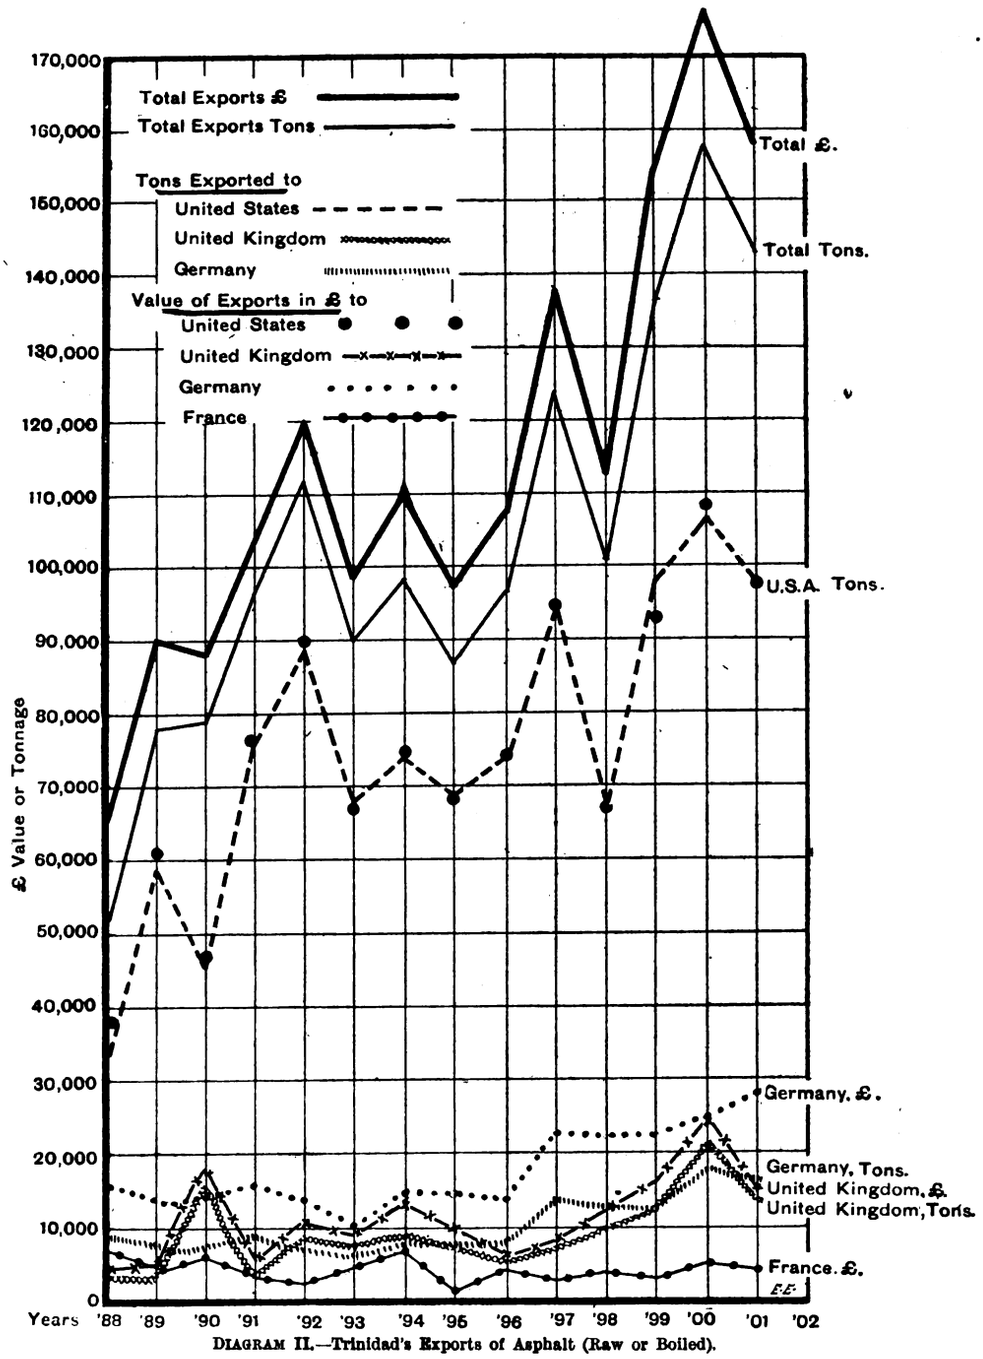

DIAGRAM II.—Trinidad's Exports of Asphalt (Raw or Boiled).

industries using this commodity. Architects for damp-courses, municipal engineers for street paving, and electrical engineers for cable insulation, are all interested in its supply. To the last-named bitumen spells "Trinidad bitumen," and it will therefore be of interest to examine how the output of this, the largest source of natural bitumen in the world, is distributed.

The yearly fluctuations of the Trinidad export trade in "asphalt, raw or boiled," are depicted in Diagram II., wherein the two upper curves denote respectively the value and tonnage. The chief purchaser is the United States, which accounts for about 60 per cent. of the output. In this case the price paid per ton has been practically £1 sterling for the 15 years under consideration, on which account only one curve representing the tonnage is shown in its entirety, while the various points on the value scale are denoted by small circles not connected by a separate curve, giving the values in each year. Separate curves are given for the value and volume of the exports to Germany. The margin between the two curves is probably due to Teutonic buying of high-grade or boiled—*i.e.*, partially refined—bitumen. Probably the resultant saving in freights is in its turn accountable for this. In the case of the United Kingdom the curves move in closer sympathy than the German curves, suggesting that this country purchases an intermediate grade, more expensive than the American while rather cheaper than the German. Only one curve is shown for France, whose purchases are relatively small and stationary both for value and volume. It will be noticed that Germany, which bulks so largely in the sources of British imports of "asphalt or bitumen," is the second largest purchaser of Trinidad asphalt.

TABLE B.—Exports of Asphalt (Raw or Boiled) from Trinidad.

	Annual average for five years ending 1892.		Annual average for five years ending 1897.		Annual average for four years ending 1901.	
	Tons.	£.	Tons.	£.	Tons.	£.
United Kingdom	7 374	9 339	7,293	9,849	14,630	17,047
United States.....	60,666	62,354	76,439	76,549	90,719	92,181
France.....	4,441	5,565	3,579	4,077	4,002	4,273
Germany.....	8,590	14,515	9,047	15,820	15,804	24,890
Other countries ...	2,166	2,957	2,967	4,506	7,408	10,401
Average annual export volume..	83,237	—	99,325	—	132,763	—
Average annual export value ...	—	94,730	—	110,801	—	128,792

The growth of exports to the United Kingdom, the United States, and Germany are evidences of the growing repute of the Trinidad product. Those who are concerned in the coal tax on British coal exports will be interested to learn that a revenue is raised by means of an export duty on the bitumen exported from Trinidad. The extent of the revenue so obtained and its proportion to the selling price are not stated in the detailed returns of the Colonial trade issued by the Colonial Office.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

TECHNICAL EDUCATION.

A great deal has been written and spoken against the educational systems of this country. We regret to say that the great majority of those who decry the education which is now given have not taken the trouble either to acquire a real knowledge of the same or of the education which is given in Germany and the States, and which they recommend as superior. It is the usual practice of such speakers and writers to judge of the value of education by the expense incurred in the erection and the maintenance of the institutions for providing the same. The fact is ignored that an undue expenditure may be even destructive to the very purpose for which the institutions or colleges were intended, as it tends to divorce theory from practice. An educational department to do valuable work needs as careful organisation and supervision as a business house. In this respect the Department of Technology organised and maintained by the City and Guilds of London Institute is a typical example of what can be done by business men. An advanced copy of the report of this department for the session 1903-4 has just been forwarded to us by Sir Philip Magnus, and is worthy of the most careful perusal by all interested in the advancement of technical education. The aid given by the City and Guilds of London Institute has led to the formation of numerous classes throughout the length and breadth of the United Kingdom, and also in India and the Colonies. Thus in 1904 there were no less than 419 centres in which instruction on some of the sixty-six subjects of examination were given. The number of classes was 2,708, and there were 41,089 students in attendance. It is of further interest to note that of these hardly one-half sat in the examinations, and 11,293 passed with the required percentage of marks. This may seem to the uninitiated a small percentage of the total number of students, but it is a good indication of the fact that the examiners of the institute require an intelligent grasp of the subject from the students. Special stress is laid in the general report now before us on the change in the form of grants given by the Board of Education. A few years ago these grants were made on the results of examinations only, and the chief aim of a teacher was to give just sufficient information to the largest number of students possible to enable them to pass the examinations. Under the new regulations, grants are given for attendance of students at approved courses of instruction on subjects in which the teaching of science is closely associated with the application to particular trades and industries. This radical departure has already improved the strained financial conditions of many centres for giving technical education, and it enables the teacher to instruct with profit to his employers that class of student to whom an examination is distasteful. In other words, it enables instruction to be given for the sake of imparting knowledge, the ultimate end of which is not the passing of an examination. This encouragement offered by the Board of Education has already resulted in a large increase in the number of students attending registered classes of the City and Guilds of London Institute. We are pleased to note also that the number of candidates for examination from India and the Colonies is also regularly increasing. The report now before us is too long to reproduce verbatim in our columns; we are therefore compelled to give our readers the impressions which we gather from the same rather than the actual text. The report clearly shows to us that the council is under the control of business men, and is conducted on the same lines which a business man would adopt in the extension of a commercial undertaking. In the first place, every

Digitized by Google

care is taken to secure the co-operation of the trade organisations associated with the various subjects taught. Again, the report shows that the selection of teachers is a matter on which the council have bestowed considerable forethought. Not only must these teachers be properly qualified before they can be registered, but they are also required to show proficiency in the art of teaching as well as in the subject to be taught. This is most important, as too many teachers are inclined to devote their energies rather to the acquisition of advanced knowledge than to the art of clearly instructing their students in the first principles of their subject. The encouragements offered to the students themselves are good, and it is gratifying to know that most of the private scholarships and exhibitions which are awarded are offered by the City guilds, who are thus fulfilling the obligations which have been handed down to them for centuries. Of the examiners' reports on the various subjects we propose to say little. They show, however, that the examiners are critical in their requirements, and that they give useful hints to the teachers as to the points on which students' replies give evidence of defects in the instruction given. In conclusion, we would add that the work of the department is a credit to all concerned, and of inestimable service to the country.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

XIII.—On Wasters.

My Dear Young 'Un,—You have completely explained the presence of the milk in the interior of the cocoanut in your reply to my last letter. You say, "I believe the reason that the foreman wouldn't put me on the marking-off table is because he bears a grudge against me for making a waster of a shaft I was cutting a key-way in." Just so. Your foreman evidently went home to tea that day down in the mouth, slapped all his children because they were noisy, and sent them to bed, because he knew that next day he would get a dressing down from the boss about that shaft. Did this occur to your imagination, my young friend? Apparently not, for you go on to say in bitterness, "They only expect an efficiency of 98 per cent. from an up-to-date dynamo, but a workman has to be absolutely perfect before they stop grumbling at him."

Now, what I am going to say to you may seem like kicking a man in the ribs when he is down. But as I am going to do it for your good, as the parent says when he spanks, I go into the matter with a light heart and a lusty muscle.

You practically state the proposition that of every 50 pieces of work you turn out, you are entitled to make a mess of one. Let us reduce that to absurdity. Of every 50 people you meet in conversation, you are entitled to smack one in the eye. Of every 50 meals you consume, you must be expected to take potassium ferrocyanide in one. There are certain functions in human life which, to be successful at all, must be perfect every time, and engineering shopwork is one of them. I suppose it must needs be that mistakes occur, but woe to that man by whom the mistake is perpetrated. He is strongly recommended to stick his head through the central aperture of a millstone and jump into the nearest canal.

An engineering firm is run upon a close-cut profit-and-loss system nowadays Just put yourself in the place of a managing director. He is competing with a dozen other firms for an order. He quotes a price less the usual something-or-other trade discount and so much more off for cash within the month. Out of that net price he pays wages, rent, insurance, depreciation, perhaps buys a necessary tool for the job, certainly has to purchase more or less raw material, and keeps himself in clothes and tobacco. If he doesn't collar the job he gets nothing, however carefully he estimates. If he doesn't quote lowest, he probably doesn't get a look-in. Now, how is that man to be expected to estimate for 2 per cent. of silly mistakes? And if he gets trapped and finds his profits swamped by some bungling fool of a workman, how can you expect him to maintain a calm seraphic smile? When you make a waster you rob him of a certain amount of jam from his bread, and he doesn't like it.

This sort of thing reacts on you. If you make a waster, you will probably not get the sack unless you become too rampantly uneconomical. This is because the average employer has a very poor idea of the average operative. He may hoof Box out, but Cox comes in and plays the goat more giddily than ever. You will simply be written down an ass—an atom of that great unreasoning mass of come-day go-day labour that can never be trusted, must be always watched, and requires to be bullied or coaxed like an overgrown lumpish baby. In the good old happy-go-lucky days, when British manufacturers could afford to make faces at foreign competitors, they were much more imperfect and much more comfortable. But certain Yanks and Germans have shown us that to take our ease, eat, drink, and be merry is only a 50-per-cent. affair. We are fighting a deadly war game in the West of Europe—though we aren't making as much noise about it as in the Far East—and military precision is the order of the day in those of our workshops which are going to pull through.

Of course, there are some fellows who couldn't help making wasters if they were chopping firewood. Out of nothing, nothing comes. They are not always idiotic. They are very often of the most polished order of beings—an ornament to any society. Only the trouble is, they are merely ornamental. Unfortunately, this is a world of much scrapping and scuffling; engineers were never noted for over-politeness, and our ideas are grossly materialistic. The best advice that can be offered to those jack-a-dandies who are too languid to do the amount of thinking requisite to avoid disaster, is to take up the profession of book-canvassing or flunkeying, where an oleaginous form of rhetoric and a *distingué* appearance may be used with some commercial benefit to themselves. As for those poor uncouth beggars who hover between insanity and unconsciousness, they had better take up a less dangerous form of existence than engineering. They would be safer in the middle of a large field digging up potatoes with a spud.

About the finest specimen of a human waster I ever came across was a gilded youth, who was catalogued as an "improver" at a works with which I was connected. I should not have mentioned him here—there was nothing about him to mention—but for one fact. He got a splendid testimonial from the firm, and the manner thereof was this. He had crowned a series of ingenious blunders by delaying the delivery of a machine for a fortnight owing to the thorough way in which he had wrecked an important casting. To have sacked him would have involved regrettable incidents with a big shareholder. Providentially he came across an alluring job and asked for a reference. The shop foreman was asked what sort of a testimonial he would suggest. The answer was instructive. "For Heaven's sake, sir, give him the condemndest good character that can be put on paper. Say he's the best man in the shops bar none. Lay it on thicker than sugar on a wedding cake. *Get rid of him by all means!*"

The waster with influence will get the very best testimonials. But the ordinary type merely gets the sack.—Yours,

The Old 'Un.

ASSOCIATION OF TRAMWAY AND LIGHT RAILWAY OFFICIALS.

The eighth general meeting of this association will be held at the Town Hall, Wakefield, on the 2nd and 3rd prox., when there will be a reception by the Mayor and the directors of the Wakefield and District Light Railways Company at 2.30. The executive committee will present their report, and Mr. H. England will deliver his presidential address. The following papers will be read and discussed: "Speed Allowance on Tramways and Light Railways," Mr. A. R. Fearnley, Sheffield; "Cost and Maintenance of Tramway Car Wheels and Rails," Mr. A. N. Banister, Norwich; "Systems of Ticket Checking," Mr. F. Coutts, Ayr; "Mr. Raworth's System of

Digitized by Google

Regenerative Control," Mr. J. T. Hall, Devonport. The meeting will be adjourned at six o'clock precisely, and at 6.30 p.m. the members and friends will meet at the small banqueting hall of the town hall, where they will be entertained to dinner by the directors of the Wakefield and District Light Railways Company. On the following day, at two o'clock, the Wakefield tramways system will be inspected. For the convenience of those members who prefer staying in Leeds on the evening of the 2nd, the president has kindly promised to run a special car from Wakefield to Leeds on the evening of that day, and from Leeds to Wakefield on the morning of the 3rd.

THE ELECTRICAL CONTRACTORS' ASSOCIATION (INCORPORATED).

[COMMUNICATED]

The first annual general meeting of the association was held at Frascati's Restaurant, 32, Oxford-street, London, W., on Tuesday, Oct. 18, 1904, at 5 p m., for the purpose of considering the report of the Central Board, and the transaction of the ordinary general business of the association required to be dealt with at such meeting. There were present Mr. W. R. Rawlings, supported by Messrs. Hogan, Marryat, Berry, McDermott, Cross, Martin, Woodward, Usher, Wallis, Steinthal, Joseph, and a number of other gentlemen.

Mr. RAWLINGS, in opening the meeting, welcomed the representatives from Ireland, Scotland, and the provinces to London. The SECRETARY then read the minutes and notice of meeting, which were confirmed.

The PRESIDENT in his report recounted the earlier history of the association, the negotiation and agreement with the manufacturing houses, and urged members to act loyally to the agreement. He eulogised the work of the Joint Committee, and incidentally mentioned the establishment of a branch and the opposition to the Sheffield Corporation. He dwelt at some length on the reconstitution and the incorporation, together with the aspirations of the association, and explained the composition of the Central Board, sectional Boards, and local branches, and the responsibility of members in making the association a success.

The TREASURER then presented his financial statement, showing the deficit of £165. 10s 6d. This, he explained, was more apparent than real, as the subscriptions due on May 1 last had not been called in yet, and when they came to hand would pay all outstanding accounts and leave a balance in hand of about £100. The PRESIDENT spoke confirming this statement. Mr. MARTIN, of Glasgow, of Glasgow, moved the adoption of the balance-sheet as presented, and Mr. WALLIS, of Leeds, seconded it, motion being carried unanimously.

Mr. STEINTHAL then proposed that the subscriptions for members of all classes should be two guineas per annum, and that the entrance fee for members and fellows be two guineas, and the entrance fee for associates be one guinea. These to be fixed amounts. Mr. WOODWARD suggested the probability of there being a big balance in hand at the end of the year, and proposed, with the idea of introducing new blood, that the entrance fee be one guinea to all classes, and that subscriptions for all members, fellows, or associates be one guinea also. The PRESIDENT replied, pointing out the expenses to be met, such as the salary of the permanent secretary and other outgoings. Mr. Steinthal's motion was carried, with two dissentients

Mr. MCDERMOT then moved, "That this meeting accept the recommendation of the Central Board, and confirm the purchase of the *Electrical Contractor* for the sum of £200." Mr. BERRY seconded it, and the motion was carried unanimously.

Mr. BERRY proposed that the following gentlemen, Messrs. Cross, Steinthal, Hogan, and Marryatt, be elected honorary fellows. Mr. NOBLE seconded, and the motion was carried by acclamation. Mr. SHAW then moved that Messrs. Rawlings, Berry, and McDermot be elected honorary fellows. Mr. MARTIN seconded. Mr. JOSEPH moved an amendment to the effect that the three gentlemen be elected simply fellows. There was no seconding. The HON. SOLICITOR (Mr. R. Tweedie Smith) then explained the difference between fellow and honorary fellow and the difference in other grades. At this point there was some little misunderstanding on the part of Messrs. Woodward and Joseph, so Mr. MARTIN proposed, and Mr. STEINTHAL seconded, that Mr. R. Tweedie Smith be elected to the chair for the time being. The HON. SOLICITOR then explained at great length, and in exceedingly good temper, the position as explained by the articles of association. Mr. MARTIN then proposed that Messrs. Rawlings, Berry, McDermot, and Wright be elected honorary fellows. Mr. SHAW seconded it. The motion was put to the meeting, but as it was not unanimous, Messrs. Rawlings, Berry, and McDermot refused to accept the honour. With regard to Mr. Wright, Mr. Martin undertook to inform him of the motion, and no doubt he would signify his acceptance or not. Mr. BERRY then proposed that Mr. Woodward be elected a fellow, Mr. RAWLINGS seconded it, and Mr. CROSS supported. The motion was carried unanimously.

The following reports from the sectional Boards was then taken. For London, Mr. HOGAN spoke on the excellent progress of the association; and Mr. BERRY, continuing the same subject, eulogised the work of his predecessors, and gave a glowing description of the future prospects. For Manchester, Mr. MCDERMOT reported progress, gave details of the large fire in Manchester, and produced Press reports thereon stating that a large number of fires attributed to fusing did not arise from that cause at all, and that it behoved all branches of the association to investigate all fires attributed to electricity, to take strong and immediate action, and to see that the Press reports were correct, as sufficient harm to the industry had already been accomplished by false reports. For Glasgow, Mr. MARTIN reported, and expressed his gratification at the spirit he had seen displayed, and mentioned the association's opposition to the Glasgow Corporation, and to their conference with the consulting engineers of Glasgow and the favourable result thereof.

Mr. R. TWEEDIE SMITH then gave a very interesting address on the subject of municipal trading, defining the sphere thereof which concerned the public welfare, that no corporation should enter into competition with private enterprise where the latter was sufficient for the purposes concerned. He referred to the Stoke Corporation and to the stopping of the contracting department, and to the necessity of contractors co-operating by canvass. He referred to the efforts with respect to Newport and Ayr. He pointed out that the municipalities were indebted to the extent of £146,000,000, which had been devoted by them for purposes of municipal trading. He dwelt at some length on the Leeds and Battersea Corporations and the danger of Tammany of municipal life, and referred to the necessity of enthusiastic backing of the association's efforts to defeat the London County Council Bill shortly to be placed before Parliament. Mr. RAWLINGS supported these statements. Mr. WOODWARD moved that the association be instructed to oppose municipal trading in so far as it affected the electrical profession. Mr. WALLIS seconded, and the motion was carried unanimously.

The PRESIDENT then referred to the publications of the association — namely, "The Model Specification" and the debt-collecting letter. He then read a letter from the Manufacturers' Association giving notice to terminate the agreement on Dec. 31 next, and urged the members to act up to the spirit of the agreement, taking into account the monetary advantage accruing therefrom. Mr. BERRY proposed, and Mr. CROSS seconded, that the Central Board be instructed to enquire into the possibility of establishing a contractors' supply house or make some other arrangements in the event of the notice from the Manufacturing Association being confirmed.

Mr. BERRY commented on the sacrifice which members of the Central Board had to make for the benefit of the members of the association generally, and briefly explained the working of the Joint Committee.

Mr. NOBLE proposed a vote of thanks to the president and to Mr. R. Tweedie Smith, and Mr. EDEY seconded it.

This concluded the business of the meeting.

A SCIENTIFIC INVESTIGATION INTO THE POSSIBILITIES OF GAS-TURBINES.*

BY MR. R. M. NEILSON, ASSOCIATE MEMBER.

A prophecy expressed frequently in engineering circles at the present day is that turbines actuated by hot gases, other than steam, will eventually come to the front as prime movers. The idea of employing hot gases (other than steam) to drive a turbine is by no means new, but the success of the steam-turbine has recently brought the question into prominence. Although the subject is interesting and important, and although many minds seem to be considering it, there appears to be hardly any literature on the subject, except what is found in patent records.

There is no doubt that many persons speak of the advantages of gas-turbines without duly considering the difficulties to be encountered. There are probably many others who have valuable ideas on the subject, supported in some cases by experimental data, but who are apt to let their thoughts run in a groove, and to consider (rightly or wrongly) that the only possible solution of the gas-turbine problem lies in the particular direction in which they are working.

This paper is written with the object of expressing and comparing as concisely as possible the advantages and possibilities of gas-turbines worked on different cycles, and the difficulties to be overcome to make these turbines a success. A further and more important object is to draw opinions from other engineers who have studied the question, and especially from those who have conducted experiments. If these objects are attained, even in an imperfect manner, the author believes that a foundation of knowledge will be obtained and placed on record, which will be of considerable use to engineers who may be endeavouring or about to endeavour to produce practical machines.

Carnot's formula for the efficiency of an ideal heat-engine

$$E = \frac{T_1 - T_2}{T_1}$$

is well known, but its real meaning is sometimes forgotten; and it may not be out of place here to put in a reminder that, in Carnot's cycle, *all* the heat is put in at temperature T_1, and *all* the heat withdrawn at temperature T_2. An increase in the range of temperature does not necessarily cause a thermodynamic gain, and it is possible largely to increase the range of temperature (as, for example, by superheating steam before use in a steam-engine) without thermodynamically increasing the efficiency by more than a small percentage.

If we have a gas-engine (reciprocating or turbine) working on Carnot's cycle between the limits of temperature 1,600deg. C. (2,912deg. F.) and 17deg. C., its greatest possible efficiency will be

$$\frac{(1,600+273)-(17+273)}{1,600+273} = 0{\cdot}85.$$

If the gas-engine is an explosion motor with compression to 60lb. per square inch above atmosphere, combustion at constant volume, and expansion to atmospheric pressure, the greatest possible efficiency between the same limits of temperature is only 0·50; and if the engine work on the ordinary Otto cycle with the same compression and between the same limits of temperature, the greatest possible efficiency is only 0·37.

We must, therefore, strive not so much to get the maximum and minimum temperatures respectively as high and as low as possible, but to get the mean temperature at which heat is given to the gas and the mean temperature at which heat is withdrawn from it respectively as high and as low as possible. Of these two temperatures the lower one is usually by far the more important. An ideal gas-engine working on Carnot's cycle between the limits of temperature 2,000deg. C. (3,632deg. F.) absolute and 300deg. C. (572deg. F.) absolute will lose as much by an increase of 100deg. C. to the lower temperature as it will by a decrease of 500deg. C. from the higher temperature.

Coming now to discuss more particularly gas-turbines, there are four cycles on which it seems to the author that these could be worked with the possibility of good results. Two of these are what Mr. Dugald Clerk designates type 2 and type 3.* The author will call them respectively cycle I. and cycle II. The author has not considered it worth while to discuss the Carnot cycle at length, but a few remarks are made about it towards the end of the paper. A pressure-volume diagram of an engine working on cycle I. is shown in Fig. 1, and an entropy-temperature diagram in Fig 2 The working fluid is compressed adiabatically from A to B. Heat is then supplied by combustion at constant pressure from B to C. The gas then expands adiabatically from C to D. The fluid is then cooled at constant pressure from D to A. Reciprocating gas-engines have been worked on this cycle by Brayton and others, but have never come into common use. (The Diesel engine may be considered to belong to this class, although no decided constant pressure line is discernible

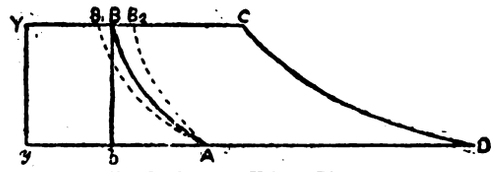

FIG. 1.—Pressure-Volume Diagram.

on indicator diagrams taken from the engine.) One great difficulty that has been experienced in working reciprocating engines on this cycle is that of getting complete combustion during the period B C without the charge occasionally firing back. If the air and fuel are brought into contact only on entering the cylinder, it is difficult to get good combustion during the period B C. If, on the other hand, the air and fuel are previously mixed together, it is difficult to prevent occasional firing back. Of course, the chamber in which the air and fuel are mixed may be made strong enough to stand explosions, but any back firing upsets the regular working of the engine, and is otherwise objectionable.

It has been proposed for gas-turbines to cause air and fuel to unite in a nozzle which thereafter diverges, with the idea that the air and fuel will combine on meeting each other, and the hot products of combustion then acquire a high velocity in the divergent nozzle, with which velocity they will enter the turbine buckets. The results of a

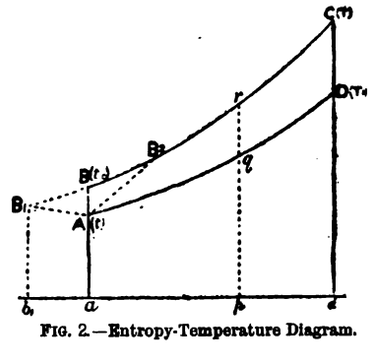

FIG. 2.—Entropy-Temperature Diagram.

trial of such a scheme would be interesting. The author doubts if the combustion would be quick enough to give a good efficiency. If, however, a combustion chamber of ample size were provided in which the burning gases could rest a short interval before passing to the turbine, better results could, in the author's opinion, be expected. The air and fuel would be separately pumped into the chamber from which the products of combustion would flow continuously and uniformly by one or more passages into the turbine.

At any rate the difficulties should not be as great with turbines working on this cycle as with reciprocating engines, as the latter have to receive the hot gases intermittently while the turbine receives a continuous flow. This is an important point as regards controlling the flame. With an engine of the Brayton type the fuel has to be ignited in the cylinder for every working stroke, and the supply of gas to the flame has to be cut off for every working stroke. With a turbine the fuel and air could be

* Paper read before the Institution of Mechanical Engineers.

* "The Gas and Oil Engine," by Dugald Clerk (Longmans and Co.), chapter iii.

Digitized by Google

supplied at a constant velocity to the flame and a steady flame maintained without interruptions. This is important, because if a mixture of air and fuel be always supplied to the flame with a velocity greater than the velocity of propagation of the flame, there can, of course, be no firing back, and this result can be obtained without the use of a wire-gauze screen. The maintaining of this velocity of supply to the flame above the required minimum when starting and stopping the motor, and when running at low powers is, of course, a problem to be considered, and some consideration is given to it later on. The strength of the mixture of air and fuel should be kept constant. The power of the turbine can be varied by other means, which will be referred to later. It must be noted that if the air and fuel are compressed adiabatically to a sufficient extent, which depends on the nature of the fuel, combustion will occur immediately the two are brought into contact with each other. It is therefore necessary in such cases to keep the air and fuel apart until the instant when combustion is desired. It must also be noted that with a turbine there will be no hot waste gases mixed with the fresh air and gas to be compressed.

This cycle allows of a fairly high ideal efficiency being obtained with a moderate maximum temperature. Now, a moderate maximum temperature is of the utmost importance in the case of a turbine of the Parsons type. A Parsons turbine with steel blades could probably be designed without any great difficulty to stand a temperature of about 700deg. C. (1,292deg. F.) without any water jacketing or cooling devices of any sort (except for the bearings). With temperatures above this, the blades would need to be cooled. This would necessitate a radical alteration in design. The question of designing a turbine to stand high temperatures will be considered later on.

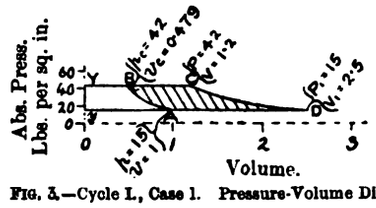

FIG. 3.—Cycle L, Case 1. Pressure-Volume Diagram.

It is only desired here to point out the great difficulties with a certain class of turbine are avoided by keeping the maximum temperature moderate. The cycle we are considering may therefore have great advantages for turbines.

It had better be stated here that the author has made several assumptions with regard to the working fluid or fluids. These assumptions are as follows: (1) That the specific heats of gases dealt with are constant at all temperatures and pressures, and are as follows: specific heat at constant pressure or $K p = 0{\cdot}238$; specific heat at constant volume or $K v = 0{\cdot}17$. (2) That weight per cubic foot of gases dealt with = 0·0777lb. at a pressure of 15lb. per square inch absolute and a temperature of 17deg. C. (3) That $\frac{P V}{T}$ = a constant for all pressures and temperatures. (4) That P V = a constant for isothermal expansion and compression at all temperatures and pressures. (5) That combustion produces no change of volume except that due to change of temperature.

Some of these assumptions will probably be appreciably inaccurate in certain cases, but it seemed advisable to sacrifice something for simplicity and uniformity. As regards the variability of the specific heats, it seemed advisable to assume constancy until more knowledge on the subject has been obtained and a scale of change (if any) has been agreed upon. Pressures have been reckoned in pounds per square inch, and temperatures have generally been reckoned on the Centigrade scale, although for convenience the corresponding readings on the Fahrenheit scale have also in some cases been given. The numbers on the diagrams representing pressure and temperature are all representative of absolute pressures in pounds per square inch, and temperatures on the absolute Centigrade scale.

Referring to Fig. 2, the heat absorbed by the fluid is represented in this figure by the area a B C d, and the heat abstracted or discarded by the area a A D d. The heat converted into work is represented by the area A B C D, and consequently, if E represents the ideal efficiency of an engine working on this cycle,

$$E = \frac{\text{area A B C D}}{\text{area } a \text{ B C } d}.$$

Now it can be proved* that

$$\frac{A B}{a B} = \frac{D C}{d C} = \frac{q r}{p r},$$

where $p q r$ is any ordinate cutting the lines a d, A D, and B C, which are all constant pressure lines. Therefore

$$E = \frac{A B}{a B} = \frac{D C}{d C} \quad . \quad . \quad . \quad (1)$$

Let t represent the temperature before compression.
Let t_c represent the temperature at the end of compression.
Let T represent the temperature at the end of combustion.
Let T_1 represent the temperature at the end of adiabatic expansion.

Then from equation (1) and referring to Fig. 2

$$E = \frac{t_c - t}{t_c} = \frac{T - T_1}{T}.$$

This can be proved quite well without an entropy-temperature diagram.† The diagram, however, shows the efficiency better. It is important to consider the amount of negative work done and the ratio of this to the total or

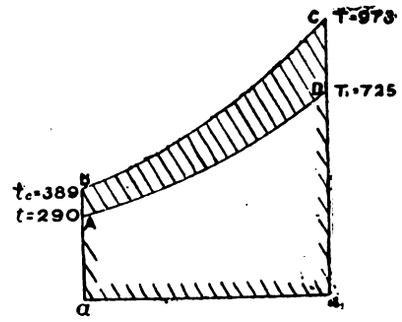

FIG. 4.—Cycle L, Case 1. Entropy-Temperature Diagram.

gross work. The negative work is the work of compressing the gas and delivering it in its compressed state. It is true that with some engines there is no work of delivery. In a reciprocating gas engine in which the gas is compressed in the motor cylinder, the only negative work (ideally) is that of compressing the charge; and, even when a separate cylinder is used for the compression, the work of delivering might be avoided. With a turbine, however, the fluid cannot be compressed in the motor; and, whatever arrangement is adopted, the compressed fluid will have to be delivered after compression. The author has therefore considered it better in all cases to include in the negative work the amount required to deliver the compressed gas. The motor proper, of course, gets the benefit of this work.

In Fig. 1 the work to compress the gas is represented by the area A b B, and the work to deliver it in a compressed state by the area y Y B b. The total negative work is therefore represented by the area y Y B A. The gross work of the motor is represented by the area y Y C D of which the part y Y B b represents the work done

* Since all vertical lines represent adiabatic expansion, therefore, by the laws of adiabatic expansion,

$$\frac{\text{temp. at A}}{\text{temp. at B}} = \left[\frac{\text{press. at A}}{\text{press. at B}}\right]^{\frac{\gamma-1}{\gamma}}$$

where $\gamma = \frac{K p}{K v}$

Similarly $\frac{\text{temp. at } q}{\text{temp. at } r} = \left[\frac{\text{press. at } q}{\text{press. at } r}\right]^{\frac{\gamma-1}{\gamma}}$

But pressure at A = pressure at q, since A q D is a constant pressure line; and pressure at B = pressure at r, since B r C is a constant pressure line,

$$\therefore \frac{\text{temp. at A}}{\text{temp. at B}} = \frac{\text{temp. at } q}{\text{temp. at } r} \quad \therefore \frac{A B}{a B} = \frac{B C}{d C} = \frac{q r}{p r}.$$

† See, for example, "The Gas and Oil Engine," by Dugald Clerk, pp. 46-48.

Digitized by Google

before expansion, and the part b B C D the work done during expansion. By deducting the negative work from the gross work the net work is obtained; this is represented by the area A B C D. This net work is the same as that represented on the entropy-temperature diagram (Fig. 2) by the area A B C D on that diagram.

CYCLE I., CASE 1.

If the gas is required to be used in a Parsons turbine without cooling arrangements the maximum temperature must not exceed 700deg. C. (1,292deg. F.). A case with this maximum temperature will now be considered: In all cases—

Let t and p represent respectively absolute temperature C. and absolute pressure (pounds per square inch) before compression.

Let t_c and p represent respectively absolute temperature C. and absolute pressure (pounds per square inch) after compression.

Let T and P represent respectively absolute temperature C. and absolute pressure (pounds per square inch) after combustion.

Let T_1 and P_1 represent respectively absolute temperature C. and absolute pressure (pounds per square inch) after expansion to atmospheric pressure.

Let v represent one cubic foot of the fluid at temperature t and pressure p.

Let v_c, V, and V_1 represent the volume of the same at t_c, p_c, T, P, and T_1, P_1 respectively.

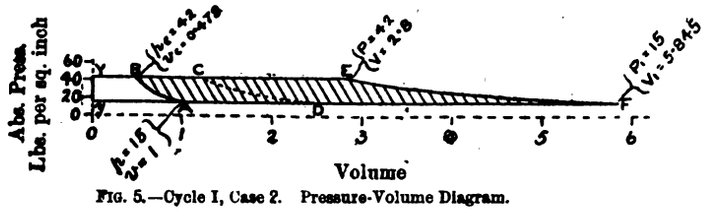

FIG. 5.—Cycle I, Case 2. Pressure-Volume Diagram.

Suppose that in all cases $t = 17$deg. C. (290deg. absolute C.), and the corresponding pressure = 15lb. absolute. Let us first try compressing to 42lb. absolute; t_c will then be 389deg. absolute C. This compression is shown by the line A B on the pressure-volume diagram (Fig. 3) and on the entropy-temperature diagram (Fig. 4). Let heat now be supplied, and the gas expand at constant pressure along the line B C till the temperature is 973deg. absolute C. Let the gas now expand adiabatically along the line C D till the pressure falls to 15lb. absolute. The fluid is now exhausted into atmosphere, and as the new charge is taken at the same pressure and at temperature t, we can assume that the discharged gas is cooled at constant pressure and used over again. We can therefore complete both diagrams by the constant pressure line D A. The heat absorbed by the fluid is represented by the area a B C d in Fig. 4, and the heat rejected by the area a A D d. The heat converted into work is represented by the area A B C D and

$$E = \frac{\text{area A B C D}}{\text{area } a \text{ B C } d} = \frac{t_c - t}{t_c} = \frac{389 - 290}{389}$$

$$= \frac{99}{389} = 0{\cdot}25.$$

The negative work is represented in Fig. 3 by the area y Y B A, the gross work by the area y Y C D, and the net work by the area A B C D.

$$\therefore \frac{\text{negative work}}{\text{gross work}} = \frac{\text{area } y \text{ Y B A}}{\text{area } y \text{ Y C D}} = 0{\cdot}4.$$

The expansion line is carried right down to atmosphere. It should be possible in practice without difficulty to very nearly do this in a turbine although the volume at D is 2½ times the volume at A. In dealing with large volumes and small pressures there is an immense difference between turbines and reciprocating engines. Reciprocating engines require large cylinders. These large cylinders, besides being objectionable on account of bulk and cost, necessitate great frictional losses. The low pressure dealt with is of little import as regards friction, which will be nearly the same whether the pressure is 13lb. below atmosphere or 13lb. above atmosphere. With a turbine, however, the large volume of the fluid does not necessitate such a bulky machine. Moreover, in a turbine the friction depends on the pressure. With high pressures the friction is great, with low pressures very small. In marine propulsion by steam-turbines it is not considered worth while uncoupling the reversing turbines when the vessel is going ahead. These turbines are allowed to rotate (above their normal speed) in the low pressure which exists at the exhaust ends of the main low-pressure turbines.

CYCLE I., CASE 2.

Seven hundred degrees C. (1,292deg. F.) must not, however, be considered as the limiting temperature for gas-turbines. We can employ a much higher temperature if we use water-cooling or other cooling arrangements. Mr. Parsons has circulated steam for heating purposes through passages formed in the rings supporting the fixed blades of his radial-flow steam-turbines.* Water could as easily be circulated, and there should be no great difficulty in passing the water also through the rings supporting the moving blades. It has been proposed by Mr. Parsons and others to circulate water or other cooling fluid through the actual blades of a turbine, these being formed hollow. It has also been proposed to keep the blades of a single-wheel turbine cool by causing the actuating fluid to act only at one point of the circumference of the wheel, while a cooling fluid is projected on to the blades at another point.

By the employment of cooling devices we might possibly

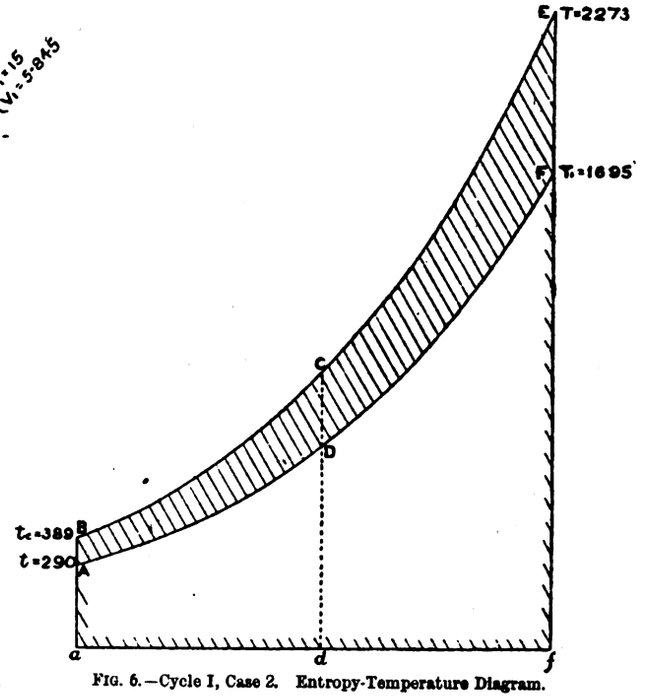

FIG. 6.—Cycle I, Case 2. Entropy-Temperature Diagram.

get a turbine to stand a temperature of 1,500deg. C. (2,732deg. F.), or even 2,000deg. C.; 2,000deg. C. is a very high temperature, and there would be great difficulty in devising and constructing cooling arrangements that would keep the blades in good working order when acted on by gas at a temperature approaching this. Let us assume, however, that 2,000deg. C. is allowable for our maximum temperature; then, if we keep the same compression as in Case 1, our ideal pressure-volume and entropy-temperature diagrams will be as shown in Figs. 5 and 6. In these figures the line C D has been reproduced from Figs. 3 and 4, and is shown in dotted lines in order that the two cases may be readily compared.

Referring to Fig. 6, the heat absorbed by the fluid is represented by the area a B E f, the heat rejected by the area a A F f, and the heat converted into work by the area A B E F. Therefore,

$$E = \frac{\text{area A B E F}}{\text{area } a \text{ B E } f} = \frac{t_c - t}{t_c},$$

$$= \frac{389 - 290}{389} = 0{\cdot}25.$$

* "The Steam-Turbine," by R. M. Neilson (Longmans and Co.), pp. 43-45.

Digitized by Google

The increase in the maximum temperature has, therefore, added nothing to the efficiency, and this will always be the case if the initial temperature and pressure are unchanged and we compress to the same amount—that is to say, as long as we start the constant pressure lines from the same points, A and B, we can extend them as far as we like to the right, and connect them by any adiabatic line we please; E will remain unchanged. In Fig. 6 the additional area d C E f is divided by the line D F in the same ratio as the original area a B C d is divided by the line A D.

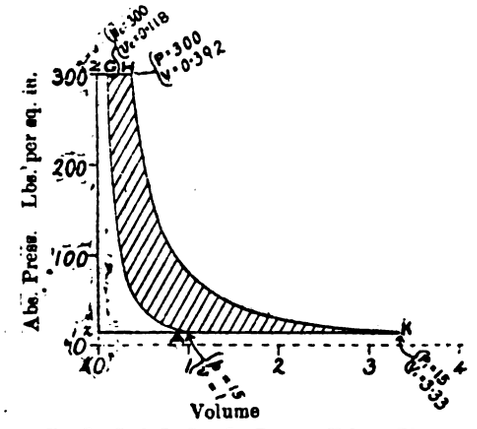

FIG. 7.—Cycle I., Case 3. Pressure-Volume Diagram.

The negative work (in Case 2) is represented in Fig. 5 by the area y Y B A; it is the same as in the last case. The gross work is represented by the area y Y E F, and the net work by the area A B E F.

$$\text{Therefore} \quad \frac{\text{neg. work}}{\text{gross work}} = \frac{\text{area } y\,\text{Y B A}}{\text{area } y\,\text{Y E F}} = 0{\cdot}171.$$

We have, therefore, very considerably diminished the ratio of negative work to gross work.

CYCLE I., CASE 3.

In Case 1 it was necessary to have a low compression, because a high compression with a maximum temperature

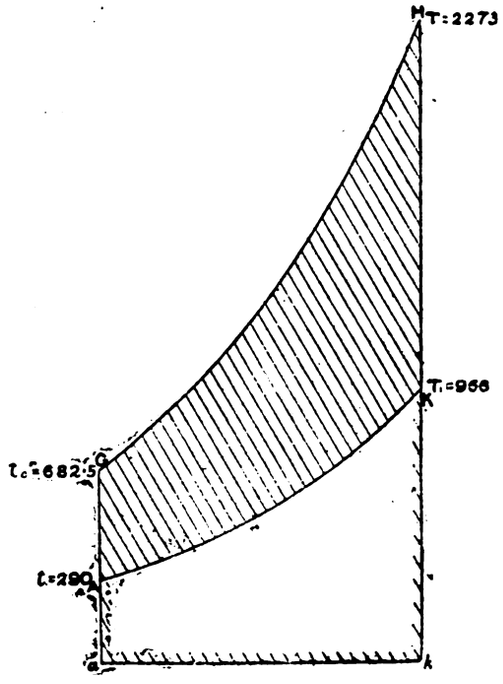

FIG. 8.—Cycle I., Case 3. Entropy-Temperature Diagram.

of only 700deg. C. would have given an impractically high value to the ratio of negative work to gross work. In fact, this ratio was high even with the low compression adopted. With the maximum temperature raised to 2,000deg. C., however, a much higher compression can be adopted. Suppose a compression to 300lb. per square inch absolute is adopted. This will make t_c 682·5deg. absolute C. The pressure-volume and entropy-temperature diagrams will then be as shown in Figs. 7 and 8.

Referring to Fig. 8, it is seen that

$$\text{E} = \frac{\text{area A G H K}}{\text{area } a\,\text{G H } k} = \frac{t_c - t}{t_c} = \frac{682{\cdot}5 - 290}{682{\cdot}5} = 0{\cdot}58.$$

which is much better than (more than double) that in Cases 1 and 2. There is, however, the inconvenience of a high compression, and compared with Case 1 more heat is likely to be lost through radiation owing to the higher average temperature. This question of radiation will be more or less important according to the type of turbine.

The negative work is represented in Fig. 7 by the area z Z G A, the gross work by the area z Z H K, and the net work by the area A G H K.

$$\therefore \frac{\text{neg. work}}{\text{gross work}} = \frac{\text{area } z\,\text{Z G A}}{z\,\text{Z H K}} = 0{\cdot}3.$$

THE PRESENT STATUS OF THE EDISON STORAGE BATTERY.*

BY A. E. KENNELLY AND S. E. WHITING.

Type E is the cell now manufactured and placed on the market in three sizes, which differ only in the number of assembled plates. The full capacity of the cell is found to be about 140 ampere-hours, which makes the total output at 30 amperes 173 watt-hours, and at 120 amperes 145 watt-hours; or the specific output 13·7 watt-hours per pound (30 2 watt-hours per kilo) and 11·5 watt-hours per pound (25 4 watt-hours per kilo) at the two rates respectively. The containing cell, as also the grids and pockets, are made of thin sheet steel plated by a special process. The jar completely encloses the element, and the lid is soldered permanently in place. There are four openings in the steel top; two of these are insulated by rubber bushings, through which the terminal posts project. The third opening is a filler hole with gastight hinge-stopper. The fourth opening is a gas vent provided with a valve and gauze screen, to prevent escape of entrained liquid. The insulation between the walls of the can and the enclosed element is all of hard rubber. On the bottom is a four-barred grating, 0·4in. deep. On the ends are ladder-like frames, giving about 0·11in. clearance, and grooved to hold the edges of the plates. On the sides are solid sheets 0·014in. thick. It has been found necessary to subject all the rubber insulation to a special chemical treatment to prevent a foaming action of the alkaline electrolyte. Between the plates are threaded four-cornered rods of rubber about 0·1in. thick and spaced 0·57in. apart. The distance between opposed plate surfaces is about 0·04in. Plates of like polarity are bolted to a horizontal bar at the top, provided with spacing washers and joined to the vertical terminal post.

For use in vehicles the cells are grouped in wooden trays containing three, four, or six cells each. Connections between cells are ingeniously made by taper lugs, and each jar is insulated from its neighbours and from the base by spacing blocks and a rubber pad respectively. The grid itself and the pockets containing the active materials are identical for both positive and negative electrodes. The grid is 9·25in. high—excluding the lug—4·75in. wide, and 0·015in. thick. It contains 24 rectangular holes, each 2·95in. high and 0·5in. wide. Into these holes are fitted pockets. These are made up of strips of 0·003in. steel, having flange edges that telescope together to form the pocket or container of the active material. These pockets have each about 5,000 perforations. The active material of the positive plate is an oxide of nickel in finely-divided form commingled with a conducting substance, such as flake graphite, in order to improve the conductivity of the mass. The active material of the negative plate is finely-divided iron similarly commingled with a conducting substance. The electrolyte is a 20 per cent. aqueous solution of potassium hydrate.

In assembling the pockets are filled with active material, closed, and inserted in the holes of the grid. The plate is then subjected to a pressure of 150 tons for the purpose, first, of flanging the pockets over the holes in the grid in order to lock them firmly in position, and, second, of corrugating the surface of the pocket in such a manner as to provide adequate elastic movement of the envelope in view of the contraction and expansion of the contents. The weight of the active material in its initial condition, and including the conducting material, is about 3·2 grm. per pocket for the nickel and 4·6 grm. for the iron plate. This represents a total quantity of 922 grm. positive active material and 662 grm. of negative active material in an E-18 cell. The weight of electrolyte per cell is 3·1lb. (1·40 kilos) at a normal density of 1·190, which represents about 25 per cent. of the total weight of the cell. The Edison cell is of the oxygen-lift type—that is to say, the process of charging consists in driving oxygen electrolytically from the negative to the positive plate. During discharge the oxygen leaves the positive plate and enters the negative plate. The chemical actions in the cell have not as yet been completely investigated. The following conditions may, however, be accepted provisionally as forming a working theory:

Condition.	Positive plate.	Electrolyte.	Negative plate.
Charged	NiO_2	KOH	
	NiO_2	H_2O	Fe
		KOH	
Discharging	$NiO_2K + H_2O$	HO	$-Fe$
	$NiO_2K + Ni_2O_3KOH$ KOH	HO H_2O	$FeO-$
Discharged	Ni_2O_3	KOH	FeO
		H_2O	
		KOH	

The cycle represented in the table shows that during discharge the electrolyte divides into potassium cations and hydroxyl anions, the former being directed toward the positive plate and the latter toward the negative plate. On arriving at these plates the ions give up their respective charges. At the positive plate the potassium robs the nickel oxide of a portion of its oxygen, and in combination with the water present forms new molecules of potassium hydrate, the original electrolyte. At the negative plate the hydroxyl ions deliver oxygen to the ion and form water. Thus the electrolyte tends to become concentrated in the pores of the positive plate and attenuated in the pores of the negative plate. Diffusion ultimately destroys this difference of concentration, and leaves the electrolyte in its original condition, since at any instant the total quantity of water and of potassium hydroxide (including the pores of both plates) remains the same.

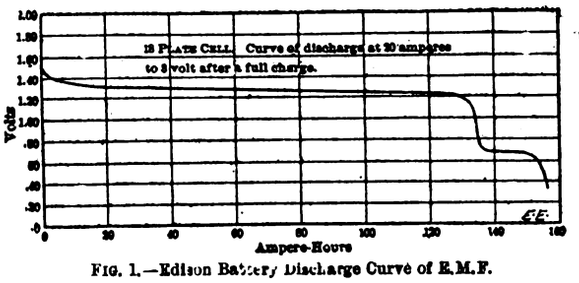

FIG. 1.—Edison Battery Discharge Curve of E.M.F.

It would appear from the form of E.M F. curve (*Fig.* 1) during complete discharge that after the cell has become almost entirely discharged other stages of oxidisation develop, and further investigation may show that the outline of the chemical cycle above presented is very incomplete. Whatever the complete cycle may be, it is in all probability, however, of the type indicated. Various observations, both of the authors and other observers, show that the discharge curve of E M.F. of the type E cell possesses the following peculiarities: (1) an initial period of rapid descent, occupying about 10 per cent. of the delivery period; (2) a nearly steady gradient of gradual descent, continuing until within about 10 per cent. of the end of the whole delivery period; (3) a final period of rapid descent, occupying the last 10 per cent. of the delivery period (assumed as stopping at a potential difference of 0·75 volt). A fair sample of this curve is represented by the heavy line in *Fig.* 1. The initial E.M.F. is influenced by the previous history of the cell, more particularly by the time which has elapsed since the close of the preceding charge. The range of initial E.M F. is between 1·35 and 1·65 volts. It would seem that this E M.F. depends upon the amount of gases remaining after the charge occluded in the pores of the cell. The E.M F. at and near the end of the discharge is also somewhat variable, depending in some measure upon the rate and nature of the discharge. It clearly accompanies the exhaustion of the active materials.

It has been observed both by the authors and by other experimenters that the internal resistance of an Edison type E cell is substantially constant during the main working portion of the discharge corresponding to *b c* in Fig. 2. Thus, in the E-18 cell the internal resistance at ordinary temperatures is about 0·0022 ohm. This would

* Abstract of a paper presented before Section C of the International Electrical Congress at St. Louis.

Digitized by Google

correspond to 0·0278 ohm in a type E similar cell weighing 1lb., or to 0·0126 ohm in a cell weighing one kilo. The internal resistance is slightly less at the beginning of the discharge, but becomes considerably greater near the end of the discharge. Since, however, this rise in resistance occurs only during a small portion near the end of the delivery, its effect in the total discharge may be neglected for most practical purposes. The internal resistance does not vary greatly with the discharge rate within the usual working limits of 0 to 150 amperes. In other words, the drop of pressure in the cell is approximately proportional to the discharging current strength. The maximum amount of power obtainable in the external circuit of any cell is $\frac{e^2}{4r}$ watts, where e is the actual E.M.F. and r the actual internal resistance of the cell. Under these conditions the cell will work at 50 per cent. efficiency with equal internal and external resistance. The energy liberated in an Edison E-18 cell is 1·3 volts × 141 ampere-hours = 183·3 watt-hours = 14·48 watt-hours per pound (31·9 watt-hours per kilo), and this liberation of energy is constant to a first approximation for all rates of discharge within the working limits. The amount of this liberated energy which is delivered in the external circuit depends only on the electrical efficiency of the circuit, or on the drop of pressure in the cell. Thus at 90 per cent. electrical efficiency, or 10 per cent. internal drop (corresponding to about 60 amperes in the E-18 cell), the externally delivered energy would be 183·3 × 0·9 = 165 watt-hours.

The charging E.M.F. of an Edison cell is approximately 1·6 volt (somewhat greater at the outset) until about 60 per cent. of the charge has been stored, when it rises to about 1·75 volt simultaneously with increased evolution of gases. The rise is therefore apparently connected with gaseous polarisation. To the E.M.F. of the cell must be added the drop in internal resistance in order to find the potential

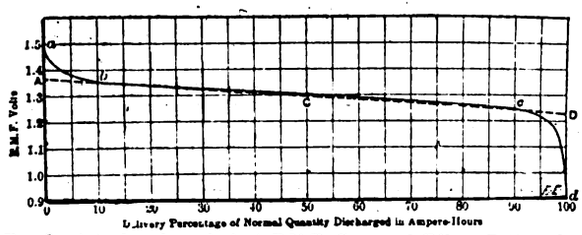

FIG. 2.—Actual and quivalent E.M.F. Curves of Edison Battery during Delivery.

difference at charging terminals. The mean E.M.F. of the cell during charge may, therefore, be taken as roughly $1\frac{2}{3}$ volts. The resistance of the cell during charge is approximately the same as during discharge, being greater at the outset of the charge, corresponding to the condition of resistance at the end of the discharge. During the charge of Edison cells bubbles of gas are liberated at both plates, oxygen at the anode or positive plate, and hydrogen at the cathode or negative plate. The collected gases form an explosive mixture.

Since the mean E.M.F. of discharge is approximately 1·3 volts, and the mean E.M.F.'s charge approximately 1·67 volts, it follows that the superior limit of watt-hour efficiency in an Edison cell is $\frac{1·3}{1·67}$, or 78 per cent. In practice it is always less than this, due to internal drop. The efficiency may best be examined, first, in relation to the voltage of charge and discharge; and, second, in relation to the electric quantity charged and discharged. If there were no drop of pressure due to internal resistance, either in charging or in discharging, and all the electricity charged in the cell (as expressed in coulombs or ampere-hours) were discharged, the ampere-hour efficiency of the cell being thus 100 per cent., the watt-hour efficiency would be 78 per cent., or thereabouts. This figure can, in fact, be approached by employing very low rates of charging and discharging—*i.e.*, by taking many hours to each process. On the other hand, the more rapid the charge and discharge the greater the internal resistance drop in the cell, and the less the efficiency even on the assumption of 100 per cent. ampere-hour efficiency. Thus at 60-ampere charging and discharging rates the potential difference in charge would average about 1·8 volts in the E-18 cell, and the potential difference in discharge would average about 1·17 volts to the 0·75-volt limit, representing a watt-hour efficiency of 65 per cent. with 100 per cent. ampere-hour efficiency.

The Edison cell would manifestly possess an ampere-hour efficiency of 100 per cent. if no gases or irreversible substances were generated in its cycle of chemical action. Thus, if a certain number of grammes of iron were reduced and a certain number of grammes of nickel were oxidised by one ampere-hour of charging current, and no other action took place, then on discharge the reconversion of these masses of active material would develop the complete ampere-hour of electricity. On the other hand, every gramme of hydrogen (or the equivalent mass of oxygen) liberated and discharged from the negative plate during charge absorbs 0·26 ampere-hour of electricity, which is not returned to the circuit during discharge. The ampere-hour efficiency of the Edison cell is therefore determined by the amount of gas escaping during the charge. This in turn depends upon the rate of charge or charging current strength, since the greater this strength the greater the drop in internal resistance, and the sooner the plates are brought to that difference of potential at which the water is rapidly decomposed.

The essential results of various tests are represented in Fig. 3. This chart gives the output of the Edison cell (per unit mass) at varying power rates of discharge. Curves I., II., and III. represent the laboratory tests obtained for type D by the Laboratoire Central d'Electricité, Mr. Hibbert, and M. Hospitalier respectively. Curve V. represents the

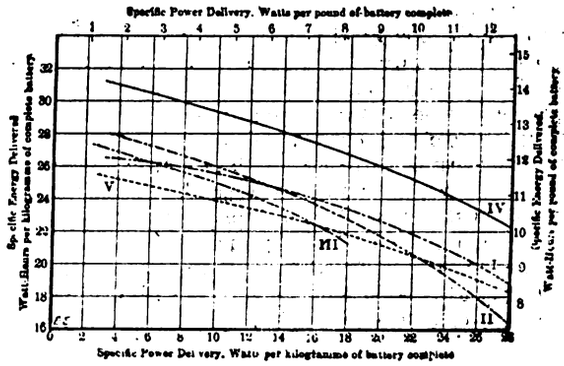

FIG 3.—Curves showing Useful Energy Delivered in Discharge to 0·75 Volt by Edison Battery.

corresponding values for the E-18 cell on normal rated capacity and delivery. Curve IV. represents, on the other hand, the corresponding values for the E-18 cell when operated under laboratory conditions of maximum capacity and delivery. In practice the output may be expected to fall between these two curves, IV. and V. Although the authors' tests of the type E cell have been confined to the E-18, 12½lb. cell, factory tests of the larger sizes of this latest show about 12 per cent. greater maximum output per unit mass than corresponds to Curve V. This may be accounted for by the lesser proportion of deadweight (solution jar and connections) than is presented in the E-18 cell.

Much experience has been attained in actual service from the Edison battery on automobiles. This experience has led to the elimination of some of the minor practical difficulties that any new battery always encounters. The successive improvements in the battery have, in fact, been due to the perception of defects discovered in actual vehicle practice. It would seem that the Edison cell is so durable that no electrical depreciation is discernible in the cells during the three years' total experience of the practical construction of the battery. No mechanical corrosion of the plates or pockets has been discernible during that time, and no depreciation seems to have yet occurred in the active material, judging from the capacity tests of cells, which are stated to be as great at the present time as they were when the cells were first constructed. The authors have recently confirmed this observation in the case of type D cells that have run nearly 3,000 miles in an automobile of the Edison Company in Boston. The capacity of these cells was found to be equal to that of new cells of the same

Digitized by Google

type. Two of these cells were opened for examination, and the sediment in them collected and dried. The dry sediment weighed 3·9 grm. and 7·1 grm. respectively, probably less than one-third of 1 per cent. of the active material in the grids. In fact, a new cell freshly set up will show about this quantity of material washed by the solution from the external surface of the plates. No signs of depreciation or corrosion appeared on any of the plates or connections.

According to observations at the factory, Edison cells lose 15 per cent. of the ampere-hour charge in eight weeks of idleness. Another test showed 11 per cent. of loss by standing one week. Hibbert's tests on type D showed 9 per cent. loss in 48 hours and 27 per cent. in 26 days. Hospitalier's tests on type D showed less than 10 per cent. loss after 24 days. A test of the authors on four type E-18 cells gave, after 26 days' idleness, 100 ampere-hours per cell. This represents a loss of 9 per cent. of the normal rated capacity of the cells, or 28 6 per cent. of the maximum rated capacity. At a corresponding charge the delivery within 24 hours would have been about 140 ampere-hours. All of the tests show that the cells are remarkably immune from deleterious effects due to careless treatment. Cells have been allowed to dry out, have been permanently short-circuited, or even charged in the wrong direction. These cells have shown full restoration of their capacity after a prolonged restoring normal charge.

Conclusions.—The Edison nickel-steel alkaline storage cell, in its large output at heavy discharge rates, its low depreciation in capacity, and its durability under severe and adverse treatment, approaches the capabilities of a piece of mechanical apparatus more nearly than is ordinarily credited to electrolytic structures. For this reason it is specially adapted to automobile service, where the treatment is abnormally arduous and severe. The authors desire to express their indebtedness to Mr. Edison for the cells which he placed at their disposal for test, as well as facilities for becoming acquainted with the facts concerning their manufacture. Also to his assistant, Mr. R. A. Fliess, of the Edison Storage Battery Company, who very kindly placed an invaluable collection of experimental data at our disposition. We are also indebted to Mr. C. L. Edgar, president of the Edison Electric Illuminating Company, of Boston, for the use of his battery in tests and information concerning the same from his assistants.

PERSONAL.

The resignation of Mr. A. Le Rossignol, general manager and engineer of the Newcastle tramways, noted in a previous issue, was accepted at the Council's meeting on Wednesday, the 26th inst.

Mr. John G. Bruce, assistant distributing engineer to the St. Pancras Borough Council, has been appointed to the position of resident electrical engineer to the Willesden Council at a salary of £250 per annum.

We are informed that Prof. Harry E. Clifford has been appointed acting head of the department of electrical engineering at the Massachusetts Institute of Technology, Boston, vice Dr. Louis Duncan, resigned.

The Reading Tramways Committee have increased the salary of Mr. Arthur G. Shearer, chief assistant engineer, from £120 to £150 per annum, in appreciation of the satisfactory manner in which he has conducted his duties.

The Blackburn Corporation are considering the following appointments: Messrs. J. H. Cowell and Johnson joint managers of the tramways at a salary of £250 each; Mr. P. P. Wheelwright manager of the electricity works at a salary of £300; to increase the salary of Mr. F. H. Corson, second assistant engineer, to £250; and to appoint a junior assistant in the electricity department.

Mr. J. W. A. Binner, chief assistant engineer of Bermondsey electricity works, who has been appointed as superintendent engineer to the Havanna Electricity Company, Cuba, was, previous to his departure, presented with a handsome dressing case, cabin trunk, and set of books by Mr. W. H. Vincent, borough electrical engineer, on behalf of the staff and employés, as a token of their good wishes for his continued success. Mr. Binner sailed from Liverpool on the 14th inst. in the "Celtic," and his future address is La Companie de Electricidad de Cuba, Aguiai 81 and 83, Havanna, Cuba.

Sale of Plant, etc.—Particulars of sale of plant and goodwill of the business of mechanical and electrical engineers carried on by W. and E. Sumner and Clementson, Limited, and of large plant which has been used for electric lighting of Messrs. Browett, Lindley, and Co.'s works, appear in another column.

LEGAL INTELLIGENCE.

THE MANCHESTER TRAMWAYS.

The case of the Manchester Carriage and Tramways Company *v.* the Swinton and Pendlebury District Council was mentioned before the Court of Appeal on Wednesday, when the defendant Council asked that the hearing should be accelerated.

Mr. Justice Channell had decided that the Council must take over a depôt in their district, and the Council are appealing against such decision.

The Court of Appeal considered that the Council had not made out a case for advancing the hearing of the matter, and the case was dismissed, with costs.

THE LAYING OF TELEPHONE WIRES.

At Brentford County Court his Honour Judge Shortt, K.C., as arbitrator under Section 3 of the Post Office Act of 1878, gave his award in the dispute between the Postmaster-General and the Brentford District Council as to the location of the telephone wires.

The Postmaster-General, to meet the needs of subscribers to the Post Office telephone system, intended to construct lines along Ealing and Hanwell roads at Brentford, but the local authority refused to sanction overhead wires. It was contended for the applicant that he had a duty cast upon him to make the service as cheap as possible in order that the lowest fees could be charged to the public, and he therefore proposed overhead wires, as the roads in question were rural in character and little populated. The overhead installation would cost £71. 4s. 7d., and the underground system £364. 5s. 6d., and the difference was so extensive as to prohibit the service being installed if the Council had its own way.

For the respondents it was urged that they had no power to incur the expense of opening and closing the trenches. The district was thoroughly served by the National Telephone Company, and no extension was needed.

His Honour stated that having visited the roads along which the lines were proposed to be run, he was satisfied, by their narrowness, that they were unfit to have poles set up in them. He did not think the extra expense of putting the wires underground sufficient excuse to outweigh this view, and he therefore found in favour of the respondents, with costs.

IMPORTANT RATING APPEAL.

At the Preston Quarter Sessions the Blackpool and Fleetwood Tramway Company appealed against an assessment by the Thornton Urban District Council, through whose district the tramway passed. Under the Public Health Act of 1875 railways are rated at one-fourth of the actual value of the undertaking, and the tramway company contend that as they pass through enclosed ground in going from Blackpool to Fleetwood their line is entitled to the privilege of a railway constructed under an Act of Parliament. If the line passed through public streets only, it was certainly a tramway, but this line, it was contended, passed through enclosed ground, which had to be obtained by compulsory powers. It was further contended on behalf of the tramway company that they had to pay railway passenger duty to the Board of Taade.

The Chairman said he could not infer from that that the tramway was a railway, and after legal argument on both sides, the Bench decided that the tramway could not be treated as a railway, and the appeal was dismissed, with costs.

The Bench agreed to state a case.

COMPANIES' MEETINGS AND REPORTS

BRITISH COLUMBIA ELECTRIC RAILWAY.

The report for the 12 months ended June 30 last, to be submitted at the meeting to-day, shows an increase in gross receipts of 138,445dol., and the net earnings, after charging renewals, an increase of 60,649dol. The following charges have been made against the revenue account—namely: provision for renewals maintenance, £13,372; bonus to employés, £2,340; amount written off preliminary and issuing expenses, £1,343; added to capital amortisation fund, £1,659; leaving as net profit for the year £49,045. The balance brought forward was £1,099, making a total of £50,144. The directors recommend a dividend on the deferred ordinary stock of 3 per cent., making 6 per cent. for the year, writing an additional amount of £2,000 off preliminary and issuing expenses, transferring to reserve fund £7,104, and carrying forward £2,222. The number of lights in use at June 30, 1904, was 112,911, an increase of 19,812. The number of passengers carried during the year was 8,869,486, an increase of 1,505,197. The construction of the Vancouver power installation is proceeding very satisfactorily. Less than one-third of the tunnel between Trout and Coquitlam Lakes remains to be driven; the concrete dam at Trout Lake, the power-house and the sub-stations have all been completed, and three pipe lines are in place. Since Dec. 18, 1903, the city of Vancouver street-lighting has been carried out by means of power delivered from Trout Lake, and a contract has been entered into to supply the city of New Westminster with power for street-lighting over a term of years. The remaining £45,000 of Vancouver power debentures have been issued during the year, making a total issue of £220,000. The additional funds required by the power company to complete construction work are being supplied by the railway company. The engineers estimate that the work will be completed about May, 1905. The negotiations for the purchase of the

Digitized by Google

Vancouver Gas Company have been successfully carried through since the end of the year now under review, and the price of electricity has been lowered.

WESTERN TELEGRAPH.

The revenue for the half-year ended June 30 amounted to £241,981 and the working expenses to £99,547. After providing £13,868 for debenture stock and debenture interest and sinking fund and £5 893 for income tax. there remains a balance of £128.672; to this is added the sum of £4,939 brought from December last, making a total of £127,611. The revenue includes £17,114 dividends upon the Company's investments in other telegraph companies and £7,322 interest on reserve fund investments. A quarterly interim dividend of £31,189 has been paid, £22,000 transferred to the general reserve fund, and £18,000 to the maintenance ships reserve fund. The directors now recommend the declaration of a final dividend of 3s. per share, making, with the interim dividends, a total dividend of 6 per cent. for the year, and also the payment of a bonus of 2s. per share, both free of income tax, which, together, will amount to £51,982, leaving a balance of £4,439 to be carried forward. The dividend and bonus will be payable on Nov. 3.

BATH ELECTRIC TRAMWAYS.

The report of the Bath Electric Tramways, Limited, for 1903 states that the construction of the Company's system was proceeding up to the end of last year, and the accounts submitted relate entirely to construction. The tramways started working on Jan. 2, 1904. Upon that date the operation of the system commenced with a small part of the mileage and with some few of the tramway cars. Both the mileage and equipment have been increased from time to time during the current year, and various sections of the line were at various dates completed and opened, until Aug. 1 last the final section of the system originally contemplated by the Company was opened for traffic, and 40 tramway cars were in use. The traffic receipts from the commencement of operations to Sept. 28, 1904, a period of 39 weeks (less two days) amounted to £25,365.

The first ordinary general meeting of the Company was held on Tuesday at Winchester House, Sir Vincent Caillard presiding.

The **Chairman** stated that an additional route was being laid out ready for construction over the Midland Bridge. Under the Company's original order it was bound to provide £11,500 for street widenings and city improvements. The term "city improvements" was very wide, but by payment of an additional £5,000 the Corporation of Bath had undertaken to reconstruct the Midland Bridge, which would have to be altered to accommodate the new route, and to release the Company from its obligation regarding any "city improvements" that might be made in the future. It was expected that the traffic all the year round would average £750 per week. During the construction of the system, owing to the conditions of the money market, the Company borrowed money privately, but it was at once going to issue £135,000 of debentures to clear off that indebtedness.

The report was adopted.

Subscriptions are invited at par for the issue of debentures to the amount of £135,000, as mentioned above. This stock will carry interest at the rate of 4½ per cent. The subscription list was opened on Wednesday.

ELECTROLYTIC ALKALI.

The annual meeting of the Electrolytic Alkali Company, Limited, was held at Liverpool last week, Mr. C. C. Connor presiding.

The **Chairman**, in moving the adoption of the report (particulars of which we gave last week), attributed the small profits to the general industrial depression. The productive power of the plant had been increased, with the result that the cost of production had been reduced.

A **Shareholder** moved an amendment that a committee be formed to enquire into the position of the Company, and that new directors and auditors be appointed.

After some discussion, the **Chairman** said that the Board would not object to the amendment, though they had the voting power to do so if they wished. The directors were willing to have investigation, as they were convinced it would show that there was no foundation for any allegations of mismanagement. He warned the meeting that when the investigation was closed he would exercise all his power as one of the largest shareholders to prevent publication of any details that would injure the Company.

The amendment was then agreed to as far as the report to a committee was concerned, and the meeting was adjourned.

NEW COMPANIES REGISTERED.

Marks and Hodgkinson, Limited.—Capital, £5,000. Object: to acquire the business of electricians and electrical engineers carried on by J. Marks and H. Clarkson.

Holroyd's Automatic Machine Syndicate, Limited.—Capital, £10,000. Object: to carry on the business of manufacturers of and dealers in automatic machinery of all kinds, engineers, electricians.

Structural, Heating, and General Engineers, Limited.—Capital, £7,500. Object: to acquire and carry on the business carried on at Sussex-street, Sheffield, under the style or firm of William Henry Sidgwick, of civil, mechanical, electrical, heating, and ventilating engineers and contractors.

Saxonia Electrical Wire Company, Limited.—Capital, £10,000. Object: to acquire, carry on, and extend the business of manufacturers of cables and insulated electric light and telephone wires, etc., at present carried on by F. S. Thomas and S. T. Smith, as the Saxonia Electrical Wire Company, at Roan Works, Roan-street, Greenwich.

Garcia Renault Electric Cars and Accumulators, Limited.—Capital, £20,000. Objects: to adopt an agreement with P. Verhaeghe, and to carry on the business of dealers in and factors and vendors of motors, accumulators, cycles, and other vehicles of all kinds (whether propelled by electricity or other motive power), mechanical, electrical, and general engineers, etc.

Pantelegraphy Publishing Company, Limited.—Capital, £100. Objects: to acquire the business of a telegraph code expert carried on by A. C. Baronio at 36, Lime-street, E.C., as the Pantelegraphy Publishing Company, and to carry on the business of compilers, printers, and publishers of telegraphic, cable, cylinder, and other codes and messages, general translators of code and cipher messages, etc.

W. Sisson and Co., Limited.—Capital, £25,000. Objects: to adopt an agreement with W. Sisson for the acquisition of the business carried on by him as W. Sisson and Co., and to carry on the business of boiler-makers, iron, brass, and metal founders, mechanical engineers, manufacturers of steam and internal-combustion engines, and all kinds of implements and machinery, smiths, tool makers, electrical engineers, etc. Registered office: Quay-street, Gloucester.

Liens Registered.

Royce, Limited (Electrical Engineers, Manchester).—Issue on Oct. 7 of £1,900 debentures, part of a series created March 27, 1903, to secure £25,000, charged on the company's undertaking and property, present and future, except uncalled capital. Trustees: Law Guarantee and Trust Society, Limited, 49, Chancery-lane, W.C. Total amount previously issued of same series, £23,100.

Uxbridge and District Electric Supply Company, Limited.—Issue on Sept. 26 of £23,400 5 per cent. debentures, part of a series created July 14, 1904, to secure £35,000. Property charged: the company's undertaking and property, present and future, including uncalled capital. No trustees. No previous issue of same series. A note is appended to the return to the effect that the previous issue of debentures has been fully satisfied.

APPOINTMENTS VACANT.

Canvassing Engineer, Wolverhampton, Oct. 31. See advertisement.

Engine-Driver, lighting and traction station in the Midlands, Oct. 31.

Improver, Perth Corporation Electricity Works. Wages 12s. per week. See advertisement.

Borough Electrical Engineer and Manager, Poplar. Salary £400 per annum. See advertisement.

Assistant Electrical Engineer, Farnworth Urban District Council. Salary £120 per annum. Applications by 31st inst.

Lecturer and Demonstrator in Electrical Engineering, New Zealand Government. Salary £300; saloon passage. Oct. 29. See advertisement.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Vienna.—The Government Railways require tenders for telegraph tape for 1905. Tenders by Nov. 5.

Melbourne.—The Federal Postmaster-General requires tenders for 6,000 yards of telegraph cable. Tenders by Nov. 15.

Crejour (Roumania).—The Municipality require tenders for construction and working of tramways for 50 years by Nov. 7.

Porto Alegro (Brazil).—The term for receiving tenders for an electricity station, already announced, has been prolonged to Nov. 30.

Guirgia (Roumania)—Tenders are required for the electric lighting of the town. Particulars from the town's secretary. Tenders by Jan. 28, 1905.

Aberaman.—The Cwmbach Co-operative Society invite tenders for electric lighting of new premises. Contractors to supply all wiring and plant necessary. Tenders to be in Secretary's hands by Nov. 4.

Arenas de San Pedro.—The Municipality require tenders for electric lighting for eight years. Particulars may be had of the Alcalde of that town, province of Avila, Spain. Tenders by Oct. 30.

Erith.—Tenders are invited for material and work in connection with the installation of electric light at the Education Committee's offices at Picardy, Belvedere. Tenders by Nov. 11. See advertisement.

Caen (France).—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1, 1905.

Liege.—Tenders are required for the construction and working (concession) of three electric tramways. A deposit of £400 is required. Particulars from the Provincial Government, Liège. Tenders by Nov. 14.

Hammersmith.—The Guardians invite tenders for a complete wiring installation for the electric lighting of their new workhouse and infirmary at Wormwood Scrubbs. Tenders to the Clerk to the Guardians by Nov. 15.

Digitized by Google

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Cumberland and Westmoreland Lunatic Asylum, Carlisle.—Tenders are required for plant. Copies of tender may be inspected at the office of the Consulting Engineer, Electricity Works, Northallerton, Yorks. Tenders to the Clerk to the Committee of Visitors by Nov. 1.

Ballinasloe (Ireland).—The Committee of the District Lunatic Asylum invite tenders for wiring the temporary buildings for 35 incandescent lamps of 16 c.p. each, at a pressure of 200 volts, and the necessary overhead cables to connect same with engine-house, and all else necessary. Tenders by Nov. 14.

Madrid.—An application has been received from Don José Xinxo for a concession for an electric tramway starting from the Plaza Rovira in Gracia and terminating at San Juan de Horta. The notice is published with a view to eliciting any applications for the same concession on more advantageous terms; such applications to be made by Nov. 10.

Craivo (Roumania).—The *Moniteur des Intérêts Matériels* (Brussels) announces that the adjudication will take place at 4 p.m. on Oct. 25 (Nov. 7) at the Mayoralty of Craïova, of the concession for construction and working of a line of tramways (mechanical traction) in the town of Craïova. The duration of the concession is fixed at 50 years. A provisional deposit of £200 is required.

Burslem (Staffs).—Tenders are invited for the supply and erection of the following electric lighting plant at the workhouse, Chell, for the Guardians of Wolstanton and Burslem Union: (Section A) water-tube boilers, with fittings; (B) feed-water heater, feed pumps, piping, etc.; (C) two 25-kw. steam dynamos and booster; (D) switchboard; (E) cables and wiring; (F) accumulators; (G) arc lamps. Tenders to Mr. J. A. Lowndes, clerk, by 12 noon on Nov. 15.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Peok and Co., 63, Leadenhall-street, London, E.C. Tenders by March 31.

Brisbane.—Tenders are invited by the Deputy Postmaster-General for the supply and delivery at the Telegraph Office Yard, Thursday Island, of 100 tubular wrought-iron telegraph poles to Specification No. 11 and Schedule No. 51, and also for the supply and delivery at the cable tanks, Thursday Island, of three nauts of submarine cable to Commonwealth Specification No. 8 (Queensland, No. 22) and Schedule No. 50. Tenders by Dec. 12. They must state the time required for delivery; this time will be counted from the date of the notification of the acceptance of the tender. Specifications and forms of tender can be obtained at the General Post Offices, Sydney, Melbourne, Brisbane, and Adelaide. Neither the lowest nor any tender will necessarily be accepted. Tenderers are required to note that Customs' duties must be included in all charges, as per clause 2 of the general conditions. All tenders sent by post must be registered.

RESULTS OF TENDERS.

Stoke.—The Guardians have accepted the tender of Blackburn, Starling, and Co., at £48, for the installation of the electric light in the workhouse. There will be 60 lights, 11 sockets, and 55 switches. There were four tenders.

Exmouth.—Mr. T. Abell has secured the contract, at £2,160, for erecting the generating station. The nearest tender was, according to the *Exmouth Chronicle*, by another Exmouth builder, at £2,170; whilst a Topsham contractor quoted £2,189.

Ilford.—The Urban District Council have accepted the tender of the British Westinghouse Company, Norfolk-street, Strand, W.C., at £670, for the supply of balancer and switchboard panel and reversible traction booster and switchboard panel.

Motors.—Messrs. Bruce Peebles and Co., Limited, 25, Victoria-street, S.W., report the acceptance of the following: Natal and Durban Railways, Durban (locomotive shops)—40 motors, averaging 10 h.p. each; Geelong Tramways—500-e.h.p. lighting and traction direct-coupled set; Oude and Rokilkhand Railway (H.M. India Office)—generators, motors, motor-generators, and balancers for railway shops, at £4,900.

Perth.—The Corporation have accepted the following tenders for the construction and equipment of about 4¾ miles of route length of tramways, constructed as single line with passing poles: permanent way and paving, including copper bonding, R. W. Blackwell and Co., 59, City-road, London, E.C.; overhead equipment, R. W. Blackwell and Co.; cables, ducts, etc., Callender's Cable and Construction Company, Hamilton House, Victoria-embankment, London, E.C.; cars and equipments, Hurst, Nelson, and Co., Motherwell, N.B.; car depôt buildings—excavator, brick, and mason work, E. McKearney, Scott-street, Perth; iron and steel work, W. Hume, Kirkside, Perth; carpenter, etc, T. Leith and Co., Victoria-street Perth; slater work, J. Buchan and Son, King street, Perth; plumber work, MacLeish, Morrison, and Co., Mill-street, Perth; plaster work, T. P Jameson, Baillieston, Glasgow; glazier and painter work, G. R. Douglas and Son, Prince's-street, Perth.

Sub-Contracts.—Messrs. Browett, Lindley, and Co., Limited, Patricroft, report the following recent orders: From Messrs. Mather and Platt, Limited, Salford, three 200-kw. engines and one 100-kw. engine for the Priddy's Hard Victualling Yard and Royal Forton Barracks, to Admiralty specifications; from Messrs. Bruce Peebles and Co., for Canada, two engines, each to drive a 250-kw. alternator, and to give a further 50 per cent. overload: from the British Westinghouse Electric and Manufacturing Company, for the Frodingham Iron and Steel Company, one 575-b.h.p. engine—this engine to be capable of giving 100 per cent. overload; from the Cellulose Fabrik Skotselven, Norway, one 40-b.h.p. engine; from Messrs. Steel Bros. and Co., London, for delivery to Rangoon, one 50-b.h.p. engine; from the Union Card Paper Company, Montreal, Canada, one 50-kw. engine; from Messrs. Campbell and Isherwood, Bootle, two 30-b.h.p. engines for shiplighting—the above orders totalling up to about 3,500 b.h.p.

Brighton.—The Town Council have received the following tenders for the installation of electric light, telephones, and fire-alarms in the diphtheria pavilion, borough sanatorium, Bear-road, Brighton:

G. Hignett and Co., 2, North-street-quadrant	£328	5	0
Private Wire and Telephone Installation Company, Limited, 5, Palmer-street, Westminster, S.W.	241	5	0
H. J. Galliers, 3, St. James's-street	240	0	0
C. G. Reed and Sons, Limited, 26, North-street	239	10	0
Wright, Methuen, and Co., 34, Pall-mall, Manchester	199	18	0
Electrical Engineering and Maintenance Company, 5, Eastcheap, E.C.	198	0	0
Page and Miles, Limited, 60, Western-road	197	15	0
A. E. Fellingham, 10, North-street-quadrant	190	0	0
Cox-Walkers, Darlington	170	18	6
G. Virgo, 40, Edward-street (accepted)	152	0	0

Rest of Brighton.

BUSINESS NOTES.

TRACTION.

Wigan.—Trial runs on the line to Ashton have proved satisfactory.

Pudsey.—The Council have instructed the clerk to publish notice of intention to apply for a provisional order.

Cambridge.—The syndicate have arranged with the Corporation for the exclusion of the Silver-street route from the tramway scheme.

Stockport.—The Corporation have passed a confirmatory resolution for the purchase of the company's undertaking at a price of £224,000.

Wolverhampton.—The last of a series of extensions was opened last week, when the Board of Trade inspected the Wednesfield route and pronounced it quite satisfactory.

Bournemouth.—The arbitration proceedings between the Corporation and the Poole Electric Tramways Company closed last Friday, when Mr. Balfour Browne addressed the arbitrators on behalf of the company.

Glasgow.—Lord Balfour of Burleigh, the arbiter appointed by the Board of Trade in connection with the dispute between the Corporation and the Paisley Tramway Company, visited Paisley on Saturday and inspected the line.

Cheshunt.—The Urban Council are considering a proposal by one of its members that the Council should stipulate with the County Council and the company for a minimum roadway width of 45ft. in connection with the proposed tramway.

Wellingborough.—Replying to a letter from the Corporation, the company state that they cannot say at present when the work of construction will actually be commenced, but that they have no intention of allowing their powers to lapse.

Blackpool.—The proposal of the General Purposes Committee that 1d stages should be allowed on the Marton route has been confirmed. There will be two such stages. A proposal to have 1d. stages on the promenade route was rejected.

Leicester.—A trial trip over the new routes, Humberstone-road, East Park-road, and Evington-road, took place on Wednesday, and this was followed by an announcement that the Humberstone-road and East Park-road sections will be opened for traffic on Tuesday next.

Belfast.—In his report upon the estimates prepared by the Corporation officials for the electrification of the tramways, Mr. Lacey, the consulting engineer, substantially agrees with such estimates. The terms of the penalty clauses in the contract are to be finally settled by the town clerk.

Leith.—The transfer of the tramways to the Corporation has been completed, and plans relating to the reconstruction for electric traction have been forwarded for approval to the Local Government Board, and also to the Corporation of Edinburgh, the latter being the road authority in respect of a portion of the system.

Handsworth.—By the invitation of the South Staffordshire Tramways (Lessee) Company, the members of the District Council and their officers inspected the tramways the other day. A special car was put on, and after a pleasant journey the party sat down to luncheon at the New Inns Hotel, when some amiable speeches were delivered.

Birmingham.—The Bill providing for tramway extensions has been drafted, and will be considered at a special meeting on the 31st inst. A deputation of ratepayers and shopkeepers attended before the Tramways Committee with a petition that alternative routes to Corporation-street and Martineau street should be adopted.

Metropolitan Railway Co.—The settlement of differences between this company and the Great Central Railway Company is announced. The latter company is to become the owner of the duplicate lines constructed by the Metropolitan Company between Neasden and Harrow, and joint owners of the section between Harrow and Quainton Road.

Coventry.—The Corporation have resolved to inform the Coventry and District Tramways Company that unless speedier progress is made with the Smithford-street extensions they will appeal to the Board of

Digitized by Google

Trade. The company are unable to accede to the application of the inhabitants for an extension of the Earlsdon section, as the outlay entailed would be somewhat heavy.

King's Norton.—At a special meeting of the District Council on Tuesday the following resolution was carried: "That the Tramways Committee be instructed to present a special report to the next meeting of the Council upon the question of all their negotiations as to the future working of the tramways in the district of the Council, and the present position of such negotiations with such recommendations thereon as they might deem advisable."

Bury.—It has been decided not to proceed with the extension of the Tottington section, but to apply for powers to continue the Elton lines through Ramsbottom to Stubbins. Under the Bill, Bury will be required to construct the line to Stubbins within three years, or the powers will pass to Ramsbottom; and if after the lines are constructed by Bury they are found to be financially successful, Bury will be compelled to continue the tramways to Edenfield within seven years of the passing of the Bill.

Accrington.—Terms have been arrived at by the Tramways Committee with the Oswaldtwistle Urban Council with respect to the running of trams up Union-road, Oswaldtwistle. In order to widen the roadway the Corporation purpose acquiring some old property in Union-road, and the Urban Council will be allowed to fix gas brackets or electric lights to the standards. The application of the Clayton-le-Moors Urban Council for a double line within the township and round Sparth-road to the Forts Arms has been refused.

Tipton.—At the meeting of the District Council on Tuesday the Tramway Committee reported that they had considered with the Council's solicitor the clauses of the agreement with the company in view of the stoppage of the cars on the Bloomfield line. They found that the company had failed to carry out several matters mentioned in the agreement, and particularly in reference to the electrification of the line. They recommended that the solicitor take steps to enforce the terms of the agreement, and that the Board of Trade be requested not to grant any further extension of the license to use steam on the line.

West Fife.—A conference of the authorities interested in the West of Fife electric tramway scheme was held last week, when the following districts were represented: Dunfermline, Inverkeithing, Cowdenbeath, Lochgelly, and Kirkcaldy. The question particularly discussed was that of municipal control. Failing this, several members voiced the opinion that there might be joint action for arranging uniform terms. After full interchange of views on the subject it was agreed to adjourn the conference until such time as plans had been submitted by the Tramway Committee and examined by the municipal and district authorities interested.

London United Tramway Co.—A conference of Middlesex local authorities was held on Tuesday at the Town Hall, Ealing, for the purpose of determining what procedure should be adopted with the view of prevailing upon the London United Tramways Company to abate "the intolerable nuisance" caused by the noise of its cars. Resolutions were unanimously passed recommending the authorities concerned to form a joint committee with power to take such steps as were necessary. The conference did not explain how the "intolerable nuisance" is to be abated, and the convenience of the tramway service to the inhabitants generally should outweigh the objections of a section of the community.

Heywood.—The Tramways Committee are not prepared to accede to the suggestion of Bury and Rochdale that Heywood should pay 5d. per car mile for working expenses. They accordingly again offer to pay 4½d. per car mile run, or in the alternative to pay the actual working costs to be fixed by an expert or by an arbitrator appointed by the Board of Trade. If this is not acceptable to Bury and Rochdale, the committee suggest that Heywood shall provide their own cars and work them, and that each Corporation shall have running powers over the lines in their respective boroughs between Bury and Rochdale, the number of cars run to be according to the length of line in the boroughs.

Huddersfield.—After a lengthy meeting on Saturday last the following resolution was passed by the tramway employés: "That this meeting of the men employed on the Huddersfield Corporation tramways enters its most emphatic protest against the proposed annual medical examination. We also decide to gratefully accept the good offices of the Trades Council with a view to their bringing pressure to bear on the Town Council, and secure that a most reasonable and equitable regulation shall be substituted for the one passed at the last Town Council meeting." It is reported that the men have decided to write to the town clerk asking him to cause the matter to be deferred six months, and if, in the meantime, any men are instructed to go to the medical officer, they are to refuse to go.

N.E.R. Electrification.—A remarkable performance in electric railway operation was accomplished recently on that portion of the line of the North-Eastern Railway near Newcastle which has been electrically equipped by the British Thomson-Houston Company, Limited. Owing to the festivities occasioned by the visit of the Channel Squadron to Newcastle, the passenger traffic on the electrified line was enormously increased, necessitating on the first day the continuous running of 86 out of the possible 89 available cars, and on the following day the full complement of cars (89) between the hours of 5 p.m and 11 p.m. Although the equipment was subjected to exceedingly heavy and usual demands, not a single breakdown or interruption to service was experienced. The successful operation of this line, one of the first and largest surface electric railways in the United Kingdom, and its ability to successfully meet sudden and heavy demands certainly augurs well for the future of heavy electric traction.

Southend.—At last week's meeting of the Town Council the borough surveyor submitted plans and estimates for the extension of the tramways from Pleasant-road and Southchurch-avenue to the Half-way House as follows: laying of the track, £7,100; making road and building sea-wall to the Half-way House, £10,560 The electrical engineer estimated that the cost of equipment would be £6,559. Having regard to the large cost of extending the roadway and sea-wall to the Half-way House, the committee thought it desirable in the present instance to limit the extension of the tramways to a point near the end of the existing paved promenade. It was recommended that the borough engineer be authorised to carry out the work of laying the permanent way as far as the end of the existing parade at an estimated cost of £2,600, and that the electrical engineer be authorised to carry out the necessary electrical equipment of such extension at an estimated cost of £5,951. In deference to the Law and Parliamentary Committee, it was decided to postpone the matter for the present.

Plymouth.—In November, 1903, the Devonport and District Tramways Company, who work all the tramways in Devonport and district, and own part of them, gave the statutory notice of their intention to apply for powers under the Light Railways Act of 1896 to construct in Devonport and Plymouth light railways, the effect of which would be to link up practically the whole of the tramway system of the Three Towns. As the result of a conference between representatives of Plymouth Corporation and the company it was arranged that the company should not proceed with their proposed scheme until after the Corporation had applied for a provisional order to construct tramways from Tavistock-road to the borough boundary. Since then the Corporation has obtained such provisional order, but up to the present no steps have been taken towards the construction of the tramways. It is now reported that the company, being of opinion that the extensions projected by them would meet a public requirement, have decided to proceed with their application to the Light Railway Commissioners.

Newcastle.—There was an animated debate at a meeting of the Corporation on Wednesday concerning the position of the electric tramway service. On the motion that the resignation of the general manager, Mr. Le Rossignol, should be accepted, Alderman Ellis, the new chairman of the committee, said that there had been reckless extravagance. Alderman Newton said that 82 men had been doing the work of 28 men, and cars were built simply to give men employment. There was a number of walking gentlemen whose only business it was to draw salaries. It was stated that the economies effected under the new *régime* amounted to nearly £20,000 per annum. The general manager's resignation has been accepted, his salary to be paid up till Dec. 9. A letter was read from Mr. Le Rossignol, in which, after recounting the progress of the tramways, he stated that since the commencement of this year the attitude of a member of the Tramways Committee had been unendurable, so that when he received the offer of an appointment in the Colonies, he decided to accept it. It is reported that, with a view to reducing expenses, the service on some of the sections will be curtailed.

Liverpool.—Responding to a vote of thanks for the ability with which he had presided over the Tramways Committee during the past year, Sir Charles Petrie, chairman of the Tramways Committee, gave last week some interesting figures showing the progress of the tramways. During the nine months ended Sept. 30, compared with the same period in 1897, which was the last year of the old company's control, the passengers had increased from 29,000,000 to 87,500,000, or 201·9 per cent.; the mileage had increased from 4,500,000 to 9,100 000, or 102·8 per cent.; and the revenue from £219,000 to £406,784, or 85·1 per cent. The average length of the 1d. fare in Liverpool was 2¼ miles. The entire length of the tramways was 101 miles, and the committee had under consideration the question of extending the tramways, and have recommended the City Council to obtain parliamentary powers this session to construct 33½ miles of additional line. Having referred to the substantial provision made for depreciation, he stated that during the next year the carriage of parcels and light merchandise would receive consideration. The scheme of light railways has been rejected, except in regard to the route from Church-lane to Eaton-road, which will be proceeded with by Bill. The discussion on tramway extensions has been adjourned. After considering a canvass of the inhabitants, the Tramways Committee recommend that the Harbourne route should be omitted. It is proposed to lengthen the route from Five Ways to Monument-road.

Salford.—The report on the year's working of the tramways shows gratifying results. The fares amounted to £198,422. 7s. 6d. In addition, £161. 18s. 1d. was received from the Manchester Corporation as the proportion of fares due to Salford for working the Bury Old-road lines, and £63. 15s. 8d. was recovered for damage done to cars, making a total income of £198,646. 1s. 8d. The expenditure on revenue account was £138,541. 6s. 4d., showing a gross profit on the year's working of £60,106. 14s. 11d. Current cost £47,986. 10s. 2d. The traffic expenses amounted to £57,508. 17s. 1d., of which £40,494 was for wages of motormen, conductors, etc., £7,649. 13s. 4d. wages for cleaners, oilers, etc., and £1,429. 17s. 3d. wages of clerks and inspectors. The profit of £60,348. 17s. 8d. was disposed of as follows: interest and redemption of loans, £34,005. 14s. 2d.; rents of lines, £10,903. 4s. 5d. (Manchester Corporation £6,355. 12s. 7d., Eccles Corporation £4,147. 11s. 10d., and Prestwich District Council £400); depreciation and renewals fund, £3,439. 19s. 1d.—the balance (£12,000) being transferred to the borough fund in aid of rates. In addition to this large contribution in relief of the ratepayers, the committee paid the sum of £5,250. 10s. 6d. in rates. The high price paid for electricity (2d. per unit) has hampered the Tramways Committee, and as the result of a vigorous protest, the Tramways Committee are now charged 1½d. The substantial saving thus effected will, it is expected, enable the committee to deal with the reserve and renewals fund in a more adequate manner.

London County Council.—The Council have decided to introduce "tokens" for use on the tramways. The Duchy of Lancaster objecting to the plan relating to the construction of the tram subway in regard to the portion near Waterloo Bridge, the Highways Com-

Digitized by Google

mittee recommend that parliamentary powers should be sought to make a slight alteration in the structural arrangements. The City Corporation have unanimously agreed to submit the Council's proposal for a tramway along the Embankment to the committees concerned for a joint report. Several members expressed approval of the scheme. Next week the Council will be asked to vote £22,500 for tramways in Rosebery-avenue. In the letter sent by the Council to the Corporation it is stated that the adoption of a circular route will enable the County Council to fully and adequately meet the requirements of the requirements of the public using its tramways, and will also to a large extent relieve the difficulties which at present exist in dealing with the traffic at the termini during the busy hours of the morning and evening. The experience which has been gained in the electrical working of the tramways has convinced the Highways Committee that the linking-up of the existing services in the manner proposed is urgently required in order that the Council may adequately cope with the fresh conditions arising from the use of mechanical power on the tramways, while, in addition, the committee feels that the new tramways will afford travelling facilities of the utmost value to those going to or returning from their work on the north side of the Thames. At the junction of Blackfriars Bridge and the Embankment the County Council proposes that both tracks should be constructed in the carriageway south of the statue of the late Queen Victoria. With regard to the method of traction for the proposed tramways on the Embankment, it is suggested that the underground conduit system should be adopted, in which case it is anticipated that some small alterations may be rendered necessary in the roadway.

LIGHTING AND GENERAL.

Beckenham.—The immediate necessity for improved lighting of the main road between Clock House Station and Kent House-road is being urged.

Wellingborough.—The Urban District Council are negotiating with the Northampton Electric Power and Traction Company as to lighting and cleaning.

West African Telegraph Co.—The directors have declared an interim dividend for the six months ended June 30 at the rate of 4 per cent. per annum.

Hampstead.—The income from the electric lighting undertaking for the six months ended Midsummer was £30,494, as compared with £24,543 during the first half of 1903.

Eccles.—The Electricity Supply Committee have under consideration a report from their engineer as to the purchase by the Corporation of electrical motors for hiring-out purposes.

Glastenbury.—The Post Office authorities are willing to erect a telephone exchange in the Shepton Mallet area. The County Council have agreed to become subscribers for the police stations.

Putney.—The Municipal Alliance have decided to lay their correspondence with the County of London Electric Supply Company on the maximum demand system before the Borough Council.

Bingley.—The Highways Committee have referred to a sub-committee the consideration of an application by the National Telephone Company for permission to lay underground telephone conduits in the streets.

New Title.—The name of the Angus Electric Light and Power Company, Limited, Montrose, has been changed to the North of Scotland Electric Light and Power Company, Limited, owing to the extension of their undertakings.

Kilkenny.—We understand that application has been made for sanction to a loan of £10,000 for electric lighting. The Citizens' Association have asked the Corporation to adopt the electric lighting scheme for the city without delay.

Bury.—Sanction has been obtained to borrow £37,060 in connection with the extension of electricity plant. The Local Government Board have postponed sanction to the borrowing of £7,500 for stores and offices until plans, etc., have been submitted.

Shildon.—The Northern Counties Electricity Supply Company are preparing for the erection of a generating station, the Council having sealed an agreement under which the company undertakes under a bond of £2,000 to complete the scheme by Jan. 1, 1905.

Newton Abbot.—The Council have informed the Urban Electric Supply Company that they are considering the desirability of purchasing a photometer from Messrs. Alexander and Co., and have asked if the company would have any objection to that means of testing.

Chatham.—The improvements at Chatham Dockyard are now well advanced, and preparations are also being made to light the dockyard with electricity. The power station has already been commenced. New and more up-to-date plant for the yard is expected before long.

Fleetwood.—An offer has been made for the transfer of the electric light and power syndicate's undertaking. The syndicate have not yet decided whether to accept the offer. The Electric Lighting Committee are awaiting further information before taking any steps in this matter.

Stock Exchange.—The Stock Exchange Committee has appointed Nov. 10 special settling day for Callender's Cable and Construction Company's further issue of £100,000 4½ per cent. first mortgage debenture stock, and have ordered the said securities to be quoted in the official list.

Mansfield.—The Electricity Committee have suggested to the Roads Committee that 10 additional arc lamps be erected. If this is done, the committee will make the charge £20 each per annum for the whole of the lamps in the borough. Another 10 arc lamps are to be erected in another road.

Kensington.—Permission has been granted to the Post Office to lay pipes for telephone wires, etc., in Stanhope-gardens, Collingham-place, Arundel-gardens, Holland-park, Hanover-terrace, Barkston-gardens, and to the Notting Hill Electric Lighting Company to extend their mains in Kensington Park-road.

Yarmouth.—The Corporation have decided to take their electricity cables under the river instead of over it as at first intended under the powers conferred by the 1897 Act. The Harbour Commissioners' officials have offered no objections to the plan of the borough surveyor, and the work is to be done about next February.

Arbroath.—The Electric Lighting Committee have agreed to recommend to the Town Council to hand over the provisional order to the Empire Electric Lighting Company, the terms being (1) that at the end of every five years the Council may be able to repurchase the order, and (2) that the Corporation can take it up at the end of 20 years as a going concern.

Hanwell.—The Council have decided to approach the Ealing Corporation and the Urban District Council of Harrow as to the terms on which they would be prepared to supply electrical energy to this Council. A proposal that steps be taken to obtain expert opinion as to how best to deal with the electric lighting order has been referred to the Lighting Committee.

Ealing.—The business manager of the electricity undertaking, in his last report, states that the record number of 62 applications for supply had been received since the previous committee meeting, the previous largest number being 46. The number of consumers now on the books was 2,187; 58 new consumers, with 1,110 lamps, had been connected, making the total number connected 80,188 lamps.

Watford.—The Local Government Board have declined to accede to the proposal of the Urban District Council to send their engineer and surveyor and their electrical engineer on a visit of inspection abroad in connection with the proposed electric pumping schemes. The electrical engineer in his last report states that the number of consumers connected to date is 360, and that the demand for current for motive power shows a satisfactory increase.

Bath Electric Tramways.—Subscriptions are invited at par for an issue of £135,000 4½ per cent. redeemable first mortgage debenture stock. The company's system is slightly over 13 miles in length of route, of which about 4½ miles is double and over 8½ miles single line. It connects Batheaston, Bathford, Weston, Twerton, and Combe Down with the centre of Bath. The first section of line was opened for traffic on Jan. 2, 1904, and the last section on Aug. 1, 1904.

Gillingham.—The resident engineer in his last report stated that the equivalent of 82 8-c.p. lamps had been connected to the mains since the previous committee meeting, making a total of 11,897 8-c.p. lamps, with 199 consumers, connected, and that applications had been received for 422 8-c.p. lamps. The engineer has been requested to submit a plan at the next meeting of the committee for the lighting of Rock-avenue. A new cable is to be laid in Trinity-road.

Liverpool.—An enquiry has been held into an application of the City Council for sanction to borrow £400,000 for purposes connected with the supply of electrical energy. Mr. Cripps (assistant town clerk) said that the undertaking was in a very prosperous condition. In 1896, when it was acquired by the Corporation, the output totalled only 1,350,000 units, while at present it was over 26,000,000 units. The additional capital funds were needed to increase the plant and works.

Luton.—The electrical engineer's last report shows that since Sept. 16 last 15,887 units have been generated, an equivalent of 502 8-c.p. lamps and one motor connected, making a total of 197 consumers with 12,429 lamps and 59 motors of 199½ h.p. Applications have been received for over 700 additional lamps and motors equal to 200 h.p. The number of units generated show an increase of 65 per cent. over the number generated during the corresponding period of last year.

Uttoxeter.—The North Staffordshire Railway Company's new electric lighting plant at the Uttoxeter Station was inaugurated last week. The installation has been carried out under the supervision of Mr. A. F. Rock, the chief of the North Staffordshire Railway electrical department. The generating station is at the new locomotive shed. The plant consists of a Bumsted and Chandler engine coupled direct to a 20-kw. dynamo. There are at present 18 arc and over 40 incandescent lamps at the passenger station, but it is intended shortly to extend the mains and light up the goods station and yard.

Marconi's Wireless Telegraph Co.—The directors have conditionally allotted to the shareholders in proportion to their holdings 30,000 shares of £1 each at the rate of one new share for every seven shares held on Oct. 24, 1904, at the price of £1 per share. No fractions of shares will be issued, and consequently holders of less than seven shares will not be entitled to participate in the *pro rata* allotment, and shareholders holding upwards of seven shares will only be entitled to one new share for each complete seven shares held. This notice does not apply to shares converted subsequent to Oct. 24, 1904.

Electricity Shares.—The best class of electric lighting shares return from 4½ to 5 per cent. The Brompton and Kensington and Charing Cross ordinary bring in 4½ per cent. To secure 4¾ per cent. the investor should buy St. James's ordinary, and for 5 per cent. he should look to Westminsters. He can secure 5½ per cent. from Edmundson's, and 5¾ per cent. from Metropolitan Electric. A new issue of 4½ per cent. second debenture stock at par is announced by the County of London Electric Supply Company. A new issue of Bath Electric Tramways debentures is noted in another column.

Glasgow.—The Corporation have agreed to supply current to consumers in Rutherglen and Pollokshaws on the same terms as to those in the city. At the last Council meeting it was proposed: "That, in consequence of the divided opinion of the Corporation as regards the present and future value of the telephone undertaking, it be remitted to the Telephone Committee to call in the services of an expert in

Digitized by Google

order to report to the Corporation as to the present state and value of the plant, and probable depreciation that will require to be given effect to, in order to avoid loss when the undertaking will be sold to the Government at a fair value 10 years hence." The motion was negatived by 30 to 4.

Erith.—The resident engineer has kept a careful record of the lamp renewals used by each lamp attendant from May 1 to Aug. 31, and found that the cost per lamp per man for this period was as follows: 1s. 4d., 1s. 9d., 1s. 8½d., and 10½d. for each. Having regard to this report, the wages of the successful competitor have been increased from 28s. to 30s. per week. Several applications have been received for the supply of current to houses in roads where any further connections to the street-lighting mains cannot be made, and upon sufficient applications being received, distributing mains will be laid. The surveyor has been directed to proceed with the erection of the transformer station on the land in Avenue-road.

Woolwich.—At a recent meeting of the Electricity Committee the Eltham electricity scheme, which was before the Council on Sept. 29, and taken back by the chairman, was again under consideration. It was agreed to again recommend it to the Council, with the addition of an extension from High-street, Eltham, to New Eltham and Foots Cray, at an additional estimated cost of £4,500. The estimated cost of the whole scheme now is as follows: Plumstead electricity station at Shooters Hill, £13,000; site and sub-station, £1,500; Shooters Hill to Eltham and Lee Green, £12,585; sites and sub-stations, £2,143. 10s.; High-street, Eltham, to New Eltham, £2,450; site and sub-station at New Eltham, £1,150; New Eltham to Foots Cray boundary, £900—£33,736. 10s.

New Issue.—The County of London Electric Supply Company, Limited, are issuing to their shareholders at par £150,000 4½ per cent. second debenture stock, being the balance of a total of £400,000 second debenture stock (ranking immediately after the issued £400,000 first debenture stock of the company), and redeemable at £105 per cent. in either of the following events: (1) the voluntary liquidation of the company, or (2) at the option of the company at any time after May 1, 1923, by the company giving six months' notice in writing. When fully paid the stock will rank for issue *pari passu* with the existing £250,000 second debenture stock. The stock may be paid up in full on allotment, and discount will be allowed on the amounts prepaid at the rate of 4 per cent. per annum.

Keighley.—The last report on the electricity undertaking shows on capital account a total expenditure up to the end of June of £48,556—£9,300 on land and £39,256 on works. On revenue account the receipts for the year amounted to £2,922. 8s., as compared with £2,102 for the previous year, and expenditure on trading account to £2,090 as against £1,933 for the year 1902-3. In addition interest, sinking fund contributions, and other payments amounted altogether to £2,454, which left a deficit for the year of £1,629. To this was added the deficit of £1,850 on last year's revenue account, making in all £3,473, £3,206 of which has been met out of the general district rate, leaving a deficit of £267 to be carried forward. There was stated to be a steady increase in demand for both private lighting and motive power, the actual increase being nearly the same as last year.

London Gazette.—The last day for receiving proofs in the estate of Charles Aubrey Smith, electrician, 23, King-street, Regent-street, W., will be held on Nov. 19, 1904. A general meeting of the members of the Metropolitan District Electric Traction Company, Limited, will be held at Hamilton House, Victoria-embankment, E.C., on Nov. 28, 1904, at 12 o'clock noon for the purpose of having an account laid before them showing the manner in which the winding-up has been conducted and the property of the company disposed of. The partnership between Julius Edward Wedekind and Tinniswood Miller, carrying on business as electricians and engineers at 43, Clerkenwell-road, London, under the style of Charles Peacock and Co., has been dissolved by mutual consent. Notices of applications for electric lighting provisional orders appear by the Ravensthorpe and Bishop's Stortford Urban District Councils.

Maidstone.—It has been decided to instal electric light at the local prison. The following statistics as to the progress of the work up to date are available: For the March quarter of 1902 the revenue was £607, 1903 £1,524, 1904 £2,210; June quarter, £528, £795, and £1,160 respectively; September quarter, £849, £1,249, and £1,875; December quarter, £1,245, £1,880, and for the December quarter, 1904, £2,800. In 1902 the revenue account therefore amounted to £3,230; 1903, £5 448; while if the December quarter comes out as anticipated, there will be approximately this year £8,046. Over £300 is now due for current for the tramways. The works' costs in 1903 totalled £2,845, and this year they are estimated to amount to £4,070. The coal costs in 1903 were for the March quarter £271; June, £209; September, £285; December, £349; 1904—March, £555; June, £312; September, £490.

Huntingdon.—During a debate last week, held under the auspices of the Trinity Social Union, Mr. W. E. Milns (of the Urban Electric Supply Company) pointed out that he was not prepared to arrange a scheme for Huntingdon, but he might say it would probably cost from £7,000 to £10,000. Water power had been suggested, but it was very deceptive, and could not be used without having also an auxiliary steam plant. The first year's profit of their company had been £1,100 at Stamford and £847 at Grantham. All their other systems in towns of under 20,000 people showed profit. In Stamford they started with 27 consumers and 2,000 lamps; the first year they had 238 and 9,000 respectively; the second 460 and 14 000; and up to September this year 540 and 18 000. Out of this number, 128 were extensions and 4,300 lamps were additions to the original installation. A motion was passed in favour of electric lighting.

Ormskirk.—The Guardians have now finally adopted to light their premises by electricity generated by themselves. They have already spent about £3,000, including about £1,500 on boilers and fittings, and a similar sum for housing the boilers and provision for electricity. The wall, the contract for the erection of which has been let to Messrs. R. Taylor and Son, will enclose the land recently purchased from Lord Derby, and, when completed, the whole of the property belonging to the Guardians will be fenced round with a 9in. brick wall. Formal consent has been given (1) to the execution of works for the purpose of lighting by electricity the workhouse of the union and the provision of boilers and other fittings in connection with the boiler-house at such workhouse; (2) to the expenditure for the above purposes of a sum not exceeding £4,750; (3) to the borrowing of the sum of £5,000, or such part thereof, as may be necessary for the purposes.

Sunderland.—An enquiry has been held into an application for sanction to borrow £25,000 for the purposes of electric lighting. Alderman Bruce (chairman of the Electricity and Lighting Committee), Mr. J. F. C. Snell (electrical engineer), Mr. J. Haswell Brown (borough accountant), and Mr. Chas. Bevan (committee clerk) attended. The latter explained that the money was required for extensions to buildings and machinery in connection with the Hylton-road and Dunning-street stations, and also extensions to mains and services to sub-stations in connection with the undertaking. Mr. Snell said the electrical undertaking had been in existence for 10 years. Last year they had 950 consumers, with a total of 197,683 8 c.p. lamps, the total kilowatts installed being 5 530. The total units sold last year amounted to 3,580,139, and the financial result was a revenue of £36,168. The engineering and management costs amounted to £19,769 leaving a gross profit of £16,359, which was allocated as follows: interest, £7,999; sinking fund, £7,114; reserve fund, £1,246. The total of the loans sanctioned for the undertaking was £288,635, and the total amount that had been expended was £286,079. Some portion of the money they were now asking leave to borrow had already been expended.

London County Council.—The Local Government Committee, in their report upon the refusal of the Postmaster-General to pay rates on the wires of the Post Office telephones, stated that the National Telephone Company, with which the Post Office was in competition, were assessed in respect of their wires, as were also municipal authorities undertaking telephonic service. It appeared to them inequitable, therefore, that no contribution in lieu of rates should be made in respect of telephone wires fixed for the Postmaster-General. Further, the policy which was being followed appeared to be contrary to the spirit of the Treasury minute dated June 25, 1874, which was to the effect that Government property should contribute to local rates on the estimated rateable value which would attach to such property if it were in private occupation. That the matter was an important one to the Council and the local authorities would be gathered from the fact that at the last quinquennial valuation the undertaking of the National Telephone Company in London was assessed at about £30,000. The Council adopted the committee's suggestion to approach the Government and to endeavour to secure the application of the Treasury minute of June 25, 1874, to the Post Office telephone undertaking; and that the metropolitan borough councils and assessment committees should be asked to support the action of the Council.

Pemberton.—The new waterworks opened last week are interesting on account of both their source and the electric pumping machinery. The water, which is collected from the whole of the gathering ground on the east of Billinge Beacon, lodges in the worked-out seams of the old disused mines of the district, which serve as a vast underground reservoir. This supply has been tapped by means of a shaft, of 12ft. diameter sunk to a depth of 66ft. A chamber has been constructed at the bottom of the shaft to receive a set of electric pumps of the same capacity as the set placed in the new engine-house at the top, which are capable of delivering 25,000 gallons per hour. A receiving lodge is at the top, constructed to hold 25,000 gallons, so that in the event of anything going wrong with either set of pumps, there is a reserve to draw upon. The pumps at the top force the water in the reserve lodge up to the township reservoirs, a distance of 1,500 yards away. The supply of the water now tapped in very dry weather makes something between 3,000 and 4,000 gallons per day, while in wet weather it reaches from 750,000 to 1,000 000 gallons per day. The two sets of pumps are driven by two 25-h.p. electric motors, which receive current from the Pemberton electric works. Trial pumping has been carried out without the level of the water being perceptibly diminished. The whole of the work has been carried out under the supervision of Mr. Geo. Heaton, the consulting engineer, and Mr. T. Partington, the electrical engineer, Mr. J. Fairhurst, of Pemberton, having been the contractor.

Southport.—An enquiry has been held into an application by the Corporation for borrowing powers for £20,000 for the purpose of extension of the electricity estate. Councillor Ingham (chairman of the Electricity Committee), the deputy town clerk (Mr. E. S. Harper), and the borough electrician (Mr. R. S. Downe) gave evidence. Mr. Harper explained that the loan was necessary in order to keep pace with the growth of the ordinary electricity undertaking. No new works of any magnitude were proposed on the present occasion. The principal item, £1,584, was for four miles of high-tension cables, which would be laid down in order to equalise the pressure in two outlying districts of the town—viz., Scarisbrick New-road and High Park and Churchtown. A sum of £6,000 was required for meters and services, and £6,000 for low-tension mains. Experience has shown that it costs about £4,000 per annum to provide meters, services, etc., and the sum they were now asking for would last for two or three years. The sum for the high-tension cables would carry them through the same time. The work would most likely be carried out in 12 months. Mr. R. S. Downe, borough electrical engineer, handed in the following estimate for electric lighting for the next three years: Four miles high-tension cable and laying, £1,584; 1,000 cast-iron pipes for crossing streets, at 7s., £350; 12 50-kw. transformers, at £60, £720; four watertight transformer tanks, at £15, £60; two sub-stations

Digitized by Google

and switchgear, at £360, £720; services and meters, at £2,000 per annum, £6,000; low-tension mains, at £2,000, £6,000; line booster, 500 amperes 50 volts, £250; battery, £1,300; automatic reversible battery booster, £400; battery room, £300; switchboard extensions, £50; equipment of meter-testing room, £150; six mechanical stokers, £479—£18,363; contingencies, £1,637—total, £20,000.

St. Marylebone.—The Finance Committee last evening reported that the London County Council have completed the loan to the Borough Council of £1,415,000 for the payment of the electric light purchase money and expenses as sanctioned by Act of Parliament, and that the temporary loans running since July 1—viz., £500,000 (with interest) from the London and Westminster Bank and £800,000 from other sources—have been duly discharged. The committee's report further states: "This Borough Council will have to pay to the London County Council the discount of £3. 5s. 2d. per cent., together with stamp duty on the bills of 1s. per cent., the bank charge for management at the rate of £200 per million, say 5d. per cent., and advertising and general expenses. As to the last item, we are not in a position to report, the amount not having been yet certified. Apart from this, the rate at which we shall have to pay will be about £3. 6s. 7d. per cent. When comparing this with the rate of interest on a loan raised in the ordinary way, with interest payable quarterly, it must be remembered that the rate of £3. 5s. 2d. is calculated, not upon the amount now received, but upon the amount which will be payable 12 months hence. Calculated upon the actual amount of money now borrowed, the rate works out at about £3. 7s. 4d. per cent. On the other hand, the fact that we shall only have to find the interest at the end of 12 months instead of quarterly means that we shall save interest upon the first three quarterly payments of interest. As this will enable us to postpone future borrowings to the amount of about £12,000 per quarter, we may fairly reckon this as worth 3½ per cent. per annum. The saving represented by this amounts to over 9d. per cent. on the whole loan. The rate, therefore, at which we shall pay works out as follows: interest on money borrowed, £3. 7s. 4d.; bill stamps, 1s.; management, 5d.—£3. 8s. 9d.; less value of postponement of interest, 9d.—£3. 8s., or a trifle over 3⅝ per cent. This represents a saving for the first year of about £1,400 on the rate of 3½ per cent. assumed in Mr. Wright's original estimates, and about £5,000 on the revised estimate of 3¾ per cent. From these sums, however, will have to be deducted the costs of the issue when ascertained."

Manchester Telephones.—The work of laying pipes underground for the carrying of telephone wires is proceeding rapidly. At the last meeting of the Telephones Committee a report was submitted by the city surveyor (Mr. T. de Courcy Meade) stating that he had prepared contract plans and specifications for laying the pipes underground on the routes indicated by the cartoon made for the committee's information. On May 21, 1903, Mr. Meade reported that it was necessary to modify some of the routes selected by the National Telephone Company, and that he was endeavouring to substitute routes away from the main thoroughfares, where the opening of the ground would cause the least inconvenience and disturbance of business. This method has been followed wherever practicable. The work has been completed under certain contracts and taken over by the National Telephone Company in three cases, and cables are now being laid. In the other cases, the report states, the laying of the pipes is in progress, and will shortly be completed. The length of pipes is 107 miles 1,476 yards, and the cost of the work under 10 contracts is £37,413. The Corporation now receive an annual rental of £1,690 for telephone easements, based on the number of subscribers and the junction boxes in use, and the rent will be increased as the system is extended. The work has been carried out under the direction of the Paving Committee, and, considering the number of streets interfered with, the complaints received of inconvenience to the public by street disturbance have been remarkably few. The city surveyor thinks that ultimately, when all the contracts are completed, the overhead telephone wires on tramway routes within the present city boundary can be placed underground. The National Telephone Company are proceeding as rapidly as possible with the cable-laying, and on some routes the number of overhead wires has already been materially reduced. The question of laying telephone pipes within the districts of Moss Side and Withington has been deferred pending the inclusion of those districts within the city. We understand that until the necessary pipes have been laid throughout the added areas, the arrangement under which all overhead telephone wires are to be removed by the company from the tram routes within the city will be suspended.

London County Council.—On Tuesday it was agreed to lend the Islington Borough Council £160,259 for the payment of outstanding loans for electric lighting. The following notices under Electric Lighting Acts and Orders were agreed to: St. Marylebone Metropolitan Borough Council, of intention to lay mains along portions of North-street (Edgware-road), Salisbury-street, Grove-road, Lissongrove, Marylebone-road, York-street, Upper Baker-street, York-place, Paddington-street, Ashland-place, North-street, South-street, High-street, Marylebone-lane, Bulstrode-street, Welbeck-street, Queen Anne-street, Chandos-street, Langham-place, Riding House-street, Wells-street, Marylebone-passage, East-street, Dorset-street, Manchester-street, Blandford-street, Baker-street, King-street, Gloucester-place, Montague-place, Seymour-place, Bryanston-place, Queen-street, Homer-street, Crawford-street, Chapel-street, Burne-street, Bell-street, Carlisle-street, Abercorn-place, Hamilton-place, Northwick-terrace, St. John's Wood-road, Aberdeen-place, Cunningham-place, Park-road, Albert-road, Abbey-road, Grove End-road, Circus-road, Wellington-road, Acacia-road, Ordnance-road, and Norfolk-road; Charing Cross and Strand Electricity Supply Corporation, to build street boxes at the junction of Wellington-street and Russell-street and in Carey-street; County of London Electric Supply Company, to lay low-tension mains along (*a*) Hotham-road, (*b*) Fontenoy-road, and (*c*) Carmalt-gardens; County of London Electric Supply Company, to lay high and low tension mains along Luttrell-street, Larpent-street, Campion-street, Upper Park-fields, Holroyd-street, Eumore-street, Tildeswell-street, and Colinette-road, and to build transformer boxes in Brenda-road and at the junction of Goldsmith-road and Hill-street; London Electric Supply Corporation, to lay high and low tension mains along portions of Tooley-street, Unicorn-passage, Parish-street, Fair-street, Tower Bridge-road, and across New Cross road, and to fix transformer boxes in Unicorn-passage, Parish-street, and Tooley-street; Metropolitan Electric Supply Company, to lay low-tension mains along portions of Eagle-street, Southampton-row, and Kingsway; Notting Hill Electric Lighting Company, to lay mains (*a*) across Westbourne grove and (*b*) along a portion of Kensington Park-road; South Metropolitan Electric Light and Power Company, to lay low-tension mains (*a*) along two new roads and a portion of St. German's-place and across Kidbrooke-grove, and (*b*) along and across portions of Vanbrugh Park-road. Notices served under orders granted to local authorities were received from the Stepney Metropolitan Borough Council of intention to lay mains along Harford-street and a portion of Bridge-street and along a portion of Narrow-street.

Bradford.—The Electricity Committee in their annual report state that the year under review has been an active one, in consequence of the inauguration of new works, modifications to existing works, and the serious breakdowns which have occurred to the plant. The planning of the lighting effects and the installation of power at the exhibition had also been carried out by the staff of the department, entailing an amount of work out of all proportion to the expenditure involved, owing to the special nature of the work and the conditions under which it had to be carried out. Early in their term of office the committee had under consideration the defects in the engines "Hylda" and "Florence." These are being put in order, and a third engine (a 1,000-kw. generator to duplicate one already supplied) is now under erection. The cost of this will be £11,142. Designs for new general supply and traction boards have been prepared by the engineer, and this will be carried out by direct labour. The total estimated cost of the work is £11,400. The rearrangement of and additions to the condensing plant have also been decided. New mechanics' and carpenters' workshops and new stores have been built at a cost of £3,820. No. 3 boiler-house has also been extended to the full length, and an order placed for the extension, at a cost of £1,431, of the coal and ash conveying plant, which had previously been on order for the first portion of this boiler-house. A new pump-room is being equipped and two Babcock water-tube boilers are under erection, while an additional Green's economiser is at the same time being provided. The total cost is £11,524. Two new reservoirs, having an effective combined capacity of 1,820,000 gallons, are being constructed under the supervision of the waterworks engineer for the storage of cooling water from the beck for surface condensing purposes. The contract has been let, and the excavations are being proceeded with. The new reservoir will not, however, be available for use until next autumn at the earliest. The work involves the straightening of the beck across the electricity works site. The cost of the work, including the reservoir, beck straightening, the first installation of cooling plant, and connections will amount to about £20,000. The committee say that the maintenance of the supply of electricity for both general and traction purposes would in any event have been onerous on account of the alterations upon the new switchgear and condensing plant works. The whole output for the general supply had been handled by means of temporary switchboard arrangements, while the traction supply had been maintained with switchgear excessively overloaded. As much as 2,585 kw. had been disabled at one time out of a total plant capacity of 7,300 kw. It had been necessary upon several occasions to run every available engine overloaded to maintain the supply, and this had only been done by increasing the output of the plant in Nos. 1 and 2 works by 600 kw. by altering the cut-off of the engine. A 300-kw. generator had been erected at Sunbridge-road, and was supplied with steam raised by the destructor. This plant was intended for use upon the traction supply, and a storage battery was being provided for use in conjunction with it for this purpose. The generator was, however, being temporarily used for supplying current for lighting purposes. As the official trial of the dust destructor had not yet been made, it was as yet too early to speak about the adequacy of the latter from a steam-raising point of view. The committee's expenditure upon this plant had been £7,823. New feeder cables have, or are at the moment, being run into various streets for the purpose of the better control of the tramway distribution. In addition to the feeder about 11,000 yards of network had been laid during the year, chiefly for the purpose of linking up detached mains previously laid. A subway under the Midland Railway between Valley-road and Midland-road had been constructed in order to provide a direct route between the works and the western section of the city, and would result in a considerable saving in the cost of mains for both general supply and tramway purposes. The approximate cost of the subway was about £1,600. The outlay upon mains extensions, exclusive of the subway, from the end of June, 1903, to June 30 last was £33,591. The price of electricity for lighting was 4d. per unit, and was subject to a discount of 2½ per cent. for prompt payment, and a free supply of incandescent lamps in proportion to the number of units consumed for incandescent lighting. The total number of consumers had increased from 1,740 to 1,923, an increase of 10½ per cent. The figures showing the number of units sold bring out the interesting fact that the current produced has increased fivefold in five years. The total units for the half-year ended June 30, 1899, was 1,019,846, and for the half-year ended June 30 last the total was 6,942,049. The total for the year 1899 was 2,416,130, and for last year 11,806,529. It is, of course, from tramway traction that the great increase has arisen, the current used for this purpose last year amounting to 7,075,300 units, as compared with 618,282 units in 1899. The demand for electricity for motive power has advanced steadily year by year—from 463,630 units in 1899 to 2,540,757 units in 1903. For private lighting the advance has not been so substantial,

Digitized by Google

though it has been steady, at the rate of about 200,000 units increase per year, the totals for the two ends of the quinquennial period being 1,275,214 and 2,133,545 units respectively. The use of electricity for public lighting has varied considerably, the totals for the five years being as follows: 59 004 units in 1899, 76,445 in 1900, 58,797 in 1901, 54,116 in 1902, and 56,917 in 1903. The total number of incandescent lamps connected is 64,024.

PROVISIONAL PATENTS, 1904.

OCT. 17.

22287. Improvements in electrical switches. Andreas Peter Lundberg and Gustaf Charles Lundberg, 18, Fulham-place, Paddington, London. (Complete specification.)

22290. Improvements in safety devices for the trolley poles of electric cars. James Hawley, Limited, and Daniel Richard Wallwork Hardman, 34, Castle-street, Liverpool.

22296. Improvements in electrical ignition apparatus for internal-combustion engines. Percy Richardson, 19, Lancaster-road, West Norwood, London.

22326. Improvements in controllers for electric motors. Philip Middleton Justice, 55, Chancery-lane, London. (The Voltage Controller Company, United States.) (Complete specification.)

22342. Improvements in arc lamp electrodes. Körting und Mathiesen Akt.-Ges., 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, Oct. 31, 1903, being date of application in Germany.) (Complete specification.)

22355. Improvements in or relating to telephone installations. Deutsche Telephonwerke R. Stock und Co. G. m. b. H., 322, High Holborn, London. (Date applied for under Patents Act, 1901, Aug. 25, 1904, being date of application in Germany.) (Complete specification.)

22362. Improvements in connection with arc lamp hoisting gear and fittings for the same. Crompton and Co., Limited, and Ernest William Abbott, 18, Southampton-buildings, Chancery-lane, London.

22364. Improvements in electrical switches. Crompton and Co., Limited, and Ernest William Abbott, 18, Southampton-buildings, Chancery-lane, London.

22368. Improvements in means for generating intermittent electric currents for ignitors of oil-engines and other purposes. Franklin Wise Howorth, 46, Lincoln's-inn-fields London. (Malcolm P. Ryder, United States.) (Complete specification.)

22369. Improvements in means or apparatus for regulating the difference of potential between portions of electric current distributing systems. Arthur Francis Berry, 46, Lincoln's-inn-fields, London.

OCT. 18.

22372. Improvements in means for trolleys or vehicles to pick up and return electric current from and to conductors they traverse and obtain motion. Robert Cooke Sayer, 11, Clyde-road, Redland, Bristol. (Complete specification.)

22401. Improved automatic signalling apparatus for electric tramway. Charles James Jewell, 12, Chesterfield-street, King's Cross, London.

22404. A simple device for preventing broken trolley wires on electric tramways from falling. William Cecil Kirwan and Kyran Quaney, 11, Brookfield-terrace, Anglesea-road, Donnybrook, co. Dublin.

22443. Combined telephone and sounding telegraph. August Hjalmar Anderson, 33, Cannon-street, London.

22470. Improvements in and relating to filaments of the kind used in incandescent electric lamps and in processes of manufacturing said filaments. Edgar Alfred Cleveland, 83, Cannon-street, London. (W. R. Whitney, United States.)

22475. Improvements in or in connection with overhead live wires or conductors. Charles William Wilson, 6, Lord-street, Liverpool.

OCT. 19.

22479. Improved electric lamp. Edward Thomas Pickup and William Tice, 1, Wellington-chambers, York-street, Westminster, London.

22505. Improvements in doors adapted to be opened and closed by electrically controlled means. Percy Wright, 34, Castle-street, Liverpool.

22511. Blowing magnet arrangement for arc light lamps. Heinrich Beck, 216, Friedrich-strasse, Berlin, Germany.

22515. Improvements in apparatus for use with the X-rays (Roentgen rays). John Orme, 2, Drayton-road, Leyton-stone, Essex.

22519. Improvements in electrical circuit makers and breakers. William Morgan and William Henry Warden Proctor, 18, Hertford-street, Coventry.

22522. Improvements in arc lamps. John Morecraft Wellington and Walter Francis Daniell, 88, Chancery-lane, London.

22529. Improvements in electrical connections. Herbert Vincent Howard, 9, Warwick-court, Gray's-inn, London.

22536. Auxiliary appliance for the prevention of the occurrence of excess pressures on switching on and off electrical installations of high voltages. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke, G. m. b. H., Germany.) (Complete specification.)

22544. Improvements relating to the overhead trolley wires or conductors of electric tramways and the like. Sidney Weiss Mitchell, 18, Southampton-buildings, Chancery-lane, London.

22574. Improvements applicable to electric steering gear for ships and for other purposes. John Smith Raworth, 46, Lincoln's-inn-fields, London.

OCT. 20.

22616. Improvements in or connected with the wiring of telephone or other electrical plants. Albert Parker Hanson, Oswaldestre House, Norfolk-street, Strand, London.

22628. Improvements in electric arc lamps. James Brockie, 33, Chancery-lane, London.

22631. Improvements in methods of exciting electromagnets by alternating electric currents. Marius Latour, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Oct. 20, 1903, being date of application in France.) (Complete specification.)

22647. Improvements in electrical resistances. Ernest Francis Moy and Percy Henry Bastie, Greenland-place, Camden Town, London.

22652. Improvements relating to circuit breakers. Frank Roll McFeatters and Adolph Frederick Christmas, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

22653. Improvements in electric motors. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke, G. m. b. H., Germany.) (Complete specification.)

22659. An improved manufacture of composition or compound for brushes of dynamo-electric machines, for bearings, and for other articles. The Morgan Crucible Company, Limited, and Charles William Speirs, 4, South-street, Finsbury, London.

22665. Improvements relating to circuit breakers. Frank Roll McFeatters and Adolph Frederick Christmas, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

OCT. 21.

22690. Improvements in electrical generators and motors. Robert Ernest Workman, 5, John Dalton-street, Manchester.

22706. Improvements in electricity meters. Chamberlain and Hookham, Limited, and Sydney Holmwood Holden, 4, New Bartholomew-street, Birmingham.

22731. Improvements relating to electrical traction overhead conductor equipment. Charles Adolph Schierwater, 10, St. George's-crescent, Liverpool.

22743. Improvements in apparatus for the electrical treatment of gases. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22744. Improvements in electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22752. Method of and apparatus for transforming alternating currents of constant voltage and frequency into continuous currents of variable voltage. George Faget, 65, Chancery-lane, London. (Complete specification.)

OCT. 22.

22768. Improvements relating to the conductors or live rails used in electric railways and the like. Richard William Scott, 3, East Mount-terrace, Haughton-road, Darlington.

22789. Improvements in dynamo-electric machinery. Siemens Bros. and Co., Limited, and John Gordon Wilson, Queen Anne's-chambers, Broadway, Westminster, London.

22793. Improvements in or relating to starting and controlling rheostats for electromotors. George Henry Hooke, 111, Hatton-garden, London.

22808. Improvements in alternating-current motors. Robert Lundell, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

22813. Improved scraper for electromagnetic separator. Ernst Heinrich Geist, Electricitäts Act.-Ges., 322, High Holborn, London. (Date applied for under Patents Act, 1901, Jan. 18, 1904, being date of application in France.) (Complete specification.)

22817. Improvements in and relating to electric power transmitting mechanism. The British Thomson-Houston Company, Limited, and Bernard Hoppe, 83, Cannon-street, London.

22818. Improvements in and relating to systems of control for electrically-operated doors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22819. Improvements in alternating-current electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22320. Improvements in and relating to variable speed windings for alternating-current motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22321. Improvements in and relating to windings for alternating-current motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22322. Improvements in and relating to alternating-current electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22323. Improvements in the control of electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Nov. 10, 1904.

1903.

22090. Manufacture of electrodes and resistances. Cornaro.

22440A. Telephone switchboards. Fairweather. (Kellogg Switchboard and Supply Company.) (Date applied for under Patents Rule 9, Oct. 17, 1903.)

23355. Electrically-operated valves, especially applicable to turbines. Warwick Machinery Company, Limited. (General Electric Company.)

23375. Electric silent discharge apparatus. Schneller and Koeleman.

24693. Apparatus for limiting electric currents. Azarola.

24630. Apparatus for the electrical transmission, reception, recording, and reproduction of sound. Craven.

24798. Electrically-driven vehicles. British Thomson-Houston Company, Limited. (General Electric Company.)

26459. Brakes for railway and like vehicles. British Thomson-Houston Company, Limited. (General Electric Company.)

26916. Means for advertising on, and indicating the routes of, electric tramcars and other electric vehicles. Walkden.

27287. Means applicable for use in suspending electroliers. Milne.

27392. Brush-holders for dynamo-electric machines. The British Thomson-Houston Company, Limited. (General Electric Company.)

27394. Alternating-current dynamo-electric machines The British Thomson-Houston Company, Limited. (General Electric Company.)

1904.

571. Means of connection between brush-holders and pillars of dynamo-electric machines and electric motors. Rees.

6716. Electric switches. Babcock. (Date applied for under International Convention, March 23, 1903.)

7247. Sealing of the ends of insulated electric conductors. Lee.

9874. Electric switches. Dunn. (Date applied for under International Convention, Aug. 25, 1903.)

10276. Electric block signal systems. Silvene.

11439. Incandescent electric lamps. O'Brien. (Date applied for under International Convention, May 25, 1903.)

16581. Electrical binding screws or terminals and the like. Bouchet. (Date applied for under International Convention, Feb. 15, 1904.)

17243. Fenders for electric cars and other vehicles. Keith.

18021. Insulating electric conductors. Kitsee.

18429. Selective telephone call mechanism. Hawxhurst.

19232. Electric arc lamps. Blondel. (Date applied for under International Convention, Sept. 9, 1903.)

19998. Current-collecting devices for electric generators and motors. Elers. (Date applied for under International Convention, Sept. 26, 1903.)

19999. Electrical transformers. Fortescue. (Date applied for under International Convention, Sept. 30, 1903.)

20277. Manufacture of incandescence bodies for electric glow lamps. Abel. (Siemens und Halske Akt.-Ges.)

NOTES.

Wireless Telegraphy.—It is reported that the Marconi Company has been requested by the Hungarian Government to establish wireless telegraphic communication between Ancona and Fiume.

The Institution.—The 1904-5 session will be opened on Thursday next, when the president, Mr. Alexander Siemens, will deliver his inaugural address, and the premiums awarded for papers read during last session will be presented. On Thursday, the 1st prox., the annual dinner will be held at the Hotel Cecil under the ægis of the President and Council, when we hope that the usual large gathering will assemble.

New Publications.—"Life and Energy," by Walter Hibbert (London, Longmans, 2s. 6d.), being an account of four addresses given at the Polytechnic Institute, and embodying an attempt at a new definition of life, with applications to ethics and religion.—The *Journal* of the Franklin Institute (America) for October contains papers on "Electrolytic Receivers in Wireless Telegraphy," by Dr. Lee de Forest; and "Telpherage," by C. J. Messer.

The American Institute.—We have received a copy of this association's *Transactions* for October, which contains a paper on the telautograph by J. Dixon, Mr. B. J. Arnold's presidential address, and the discussions on the following papers: "Long Spans for Transmission Lines"; "Synchronous Motors for the Regulation of Power Factor and Line Voltage"; and "The Theory of the Regulation of Alternators." In his address the president reviews the progress of electricity, and deals with the problem of electrifying the railroads. An abstract of his views appeared in our issue of the 21st ult.

Electro-Harmonic Society.—The next concert will be held in the King's Hall of the Holborn Restaurant on the evening of the 11th inst., which will be a ladies' night. The chair will be taken at 8 o'clock promptly by Mr. J. S. Raworth. The programme promises to be fully up to the standard of its predecessors, if it does not surpass them. Vocal music will be provided by the Misses Katherine Longland and Maggie Purvis and Mr. Wm. Forington, while the instrumental department will be in the able hands of the musical directors, Messrs. T. E. Gatehouse and A. E. Izard. There will also be selections by the orchestra. In addition, the talented artiste, Miss Helen Mar, will contribute short stories, Mr. Frederick Chester will present ventriloquial and humorous sketches, and musical sketches will be given by Mr. Astley Weaver. The hon. secretary is Mr. W. E. Lane.

Trade Marks in China.—Messrs. W. P. Thompson and Co., of 6, Lord-street, Liverpool, who have devoted special attention to the subject of patents and trade marks, state that they have received telegraphic information from China that the new regulations for registering trade marks in that country have come into force this week, and as one of these regulations is that the applications will be entertained in the order of their presentation (and the first comer will have the right of registration where there are two conflicting applications), it is very desirable that the marks of English firms shall be filed as quickly as possible. There are 54 classes into which goods are sub-divided, a compilation based largely on the English and German classification, but a decided improvement on both, and a fresh application has to be made for each class. From reports in the daily Press we gather that the new code is not viewed with unmixed satisfaction by some of the Powers chiefly concerned, and that general apathy prevails in regard to it; but prudence suggests that British manufacturers would do well to formally effect an early registration.

The Students' Section.—The opening meeting of the Students' Section of the Institution of Electrical Engineers for the session 1904-5 will be held in the library of the Institution, 92, Victoria-street, on Wednesday, the 16th inst., at 7.30 p.m., when Mr. J. Swinburne, past-president, has kindly consented to deliver an address. The following papers are down for reading at the three following meetings: Nov. 30, "Motor-Controlling Switchgear," by L. J. Pumphrey; Dec. 7, "The Gordon Electric Light Installation at Paddington, 1884-1904," by M. G. Tweedie; Jan. 18, 1905, "Notes on the Construction and Maintenance of Large Telephone Exchange Equipments," by A. L. Stanton. The students' hon. secretary (Mr. A. G. Ellis, 177, Warwick-road, Kensington), will be pleased to communicate with any student members desirous of taking part in the discussions on any of the above papers, and will be glad as far as possible to lend copies of the papers to such students.

Personal.—On Wednesday of last week Mr. W. B. Esson, M.I.C.E., M.I.E.E., was presented by the staff, foremen, and workmen of Messrs. Johnson and Phillips's electric light and power works with a handsome roll-top writing desk and revolving chair as mementoes of the 10 years he had been associated with them while acting as chief engineer and manager to the firm. The presentation took place at the Charlton works, Mr. E. A. Brandon, who had been Mr. Esson's chief assistant, acting as spokesman. In making a suitable reply, Mr. Esson remarked that from the nature of the gift which had been so generously bestowed upon him, it was evident that a good deal more work was expected from his hands.—We learn that Mr. H. H. Jeffcott has been appointed assistant in the metrological department of the National Physical Laboratory. Mr. Jeffcott, after a distinguished career at Trinity College, Dublin, in physics and engineering, during part of which he was a pupil of the late Prof. Fitzgerald, has been with Messrs. Siemens Bros. at Woolwich and Stafford for the past two years.

The American Student.—If we recollect aright, Prof. Ayrton, on returning to this country with the Mosely Commission, expressed the view that in the matter of literary attainments the English youth compares favourably with his Transatlantic *confrère*, while the latter scores in the bold and rapid application of knowledge. The *Electrical World* of New York gives the passages printed below from an essay on the subject of electricity at an examination in the neighbourhood of New York. Perhaps the author's *forte* lies in the practical side, but the literary style of the thesis rather seems to lend support to the first part of the professor's view: "Electricity is the most and greatest invention's that ever existed . . . . they invent all kinds of musical instruments such as graphaphones and phonographs and sewing machines and electric lights and trolley cars and its acts quicker than steam. Silk mills is also run by motors & Dynamos . . . . of course I think we will have flying machines in time that is run by electricity & its got a great effect in shock and electric bells in use for ill people." It is perhaps only right to add that the author was a candidate for the Civil Service.

Power Transmission. — The Central California Electric Company, which is operating three water-power electric plants transmitting electric power to Sacramento, Grass Valley, and other cities, has decided on a new water-power plant. Surveys have been made, and the preliminary engineering work is in hand. It is proposed to instal a hydro-electric plant with a capacity of about 25,000 h.p.,

Digitized by Google

and it is stated that the plant will be operated under the highest head in the world. The new installation is to be located on the banks of the American River at Alta Station, 60 miles from Sacramento in a direct line. The tail water from the present power station at Alta is to be conducted by a short canal to a point where a drop of 2,100ft. can be obtained by use of a pipe-line. The water-wheels will be constructed on lines similar to those of the Escher-Wyss wheels, built for high-head plants in Switzerland. There will be four direct-connected units, the polyphase generators to have a capacity of either 4,000 kw. or 5,000 kw. each. The turbine wheels will have the water admitted to the buckets internally, and will be about 4ft. or 5ft. in diameter. An innovation will be the high speed of the generators—750 revolutions per minute.

Iron Production in America.—The report just presented to the United States Geological Survey on the production of iron ores in 1903 shows that the yield aggregated 35,019,308 long tons. This represents a decrease of 1½ per cent. as compared with the preceding twelvemonth, which, however, was the record year. The quantity mined in 1903 considerably exceeds the united output of Great Britain and Germany for 1902. The mineral was obtained from 22 States, Minnesota, Michigan, Alabama, and Wisconsin being the leaders. Nevada was added to the list of iron-producing States. The ore was of the four general commercial classes—red hematite, brown hematite, magnetite, and carbonate. Red hematite constituted over 86 per cent. of the total. The carbonate ores showed an increase of 26 per cent. over the previous year. The regions of Lake Superior maintain their pre-eminence in iron ore production. In the State of Wisconsin the year under review witnessed the initial output of the Baraboo range, where there are believed to be substantial deposits of Bessemer ore. The total value at the mines of the 35,019,308 tons produced in 1903 was some £13,300,000, the average price per ton being 7s. 10½d., an increase of 2½d. per ton over the previous year.

Spark Lines in Arc Spectra.—The American *Physical Review* contains an abstract of a paper on the conditions which govern the appearance of spark lines in arc spectra, which was read before the American Physical Society by Mr. Henry Crew. The author examined the intermittent arc between magnesium electrodes simultaneously with the Duddell oscillograph and the spectroscope, and arrived at the following results: (1) It was found that the voltage curve of the ordinary arc thus photographed showed no extra E.M.F. at break; nor did the spectroscope show the spark line at λ 4,481. (2) When the break at the arc was quickened by means of an air blast, the extra E.M.F. at once appeared in the voltage curve and the spark line in the spectroscope. (3) When the arc was surrounded by an atmosphere of coal gas, thus bringing out the spark lines, the voltage curve showed the extra E M.F. at break. This gives the probable explanation of the effect of an atmosphere of hydrogen as noted by various observers—viz., the break is quickened—hence high extra E M.F. is introduced—hence spark lines. (4) The introduction of spark lines by use of small currents, discovered by Hartmann, is given an interpretation different from his, but in accordance with his results, with the above results, and with the modern electron theory of the arc and spark discharge.

New Storage Battery Cell.—The Dayton Manufacturing Company of Ohio, which has for several years been manufacturing storage batteries for use in train lighting, has devised a new stationary cell, a description of which appears in the *Electrical Review* of New York. The elements lie horizontally and are placed in a round glass jar. The grids are cast from lead containing a considerable percentage of antimony, which strengthens the grid and avoids warping or buckling. After the grids are pasted and the plates hardened by a special process, they are assembled into elements, the individual plates being connected together by means of hard lead bolts about ½in. in diameter. A ¹in. square steel rod is cast in the centre of these lead bolts, giving them great rigidity. The bolts are made fast by lead nuts, which serve the double purpose of spacing the plates and holding them securely in place. Between the plates are placed two sheets of porous separating material, these sheets extending about ⅛in. beyond the edges of the plates. After the elements are assembled, the edges of the plates and the nuts are electrically welded, so as to ensure perfect connections. The horizontal position of the plates makes it practically impossible for the active material to fall from the plates or to be forced out due to the action of the gases which are formed while the cells are being charged. The porous separators absorb about seven-eighths of the electrolyte required for a normal discharge, so that in case a jar should break, the flow of current will not be interrupted.

Australian Trade Marks.—Attention is directed by Messrs. Edward Evans and Co., of 27, Chancery-lane, to the fact that the new Australian Federal Trade Marks Act is shortly to be promulgated. The measure has been passed by the Legislature, and will be brought into operation immediately after the necessary formalities have been complied with. Under the Act, existing State trade mark registrations may be extended or converted into Commonwealth registrations, and thereupon the State registrations will cease. All State registrations will lapse 14 years from the commencement of the new Federal Act, or when any renewal fee would become payable thereon. The essential features of trade marks registerable under the new Act are substantially the same as those prescribed under the English Act—namely (*a*) a name of a person printed, impressed, or woven in some particular and distinctive manner; (*b*) a written signature or copy of a written signature of the person applying for registration thereof, or his predecessor in business, as a trade mark; (*c*) a distinctive device, mark, brand, heading, label, or ticket; (*d*) an invented word or invented words; or (*e*) a word or words having no reference to the character or quality of the goods and not being a geographical name used or likely to be understood in a geographical sense. It has, however, to be noted that any word or words, letter, figure, or combination of letters or figures, which do not necessarily involve any of the essential features above referred to, may be registered as a trade mark under the new Act if such have been used before Jan. 1, 1901.

Lava for Electrical Purposes.—The growing use of talc for electrical purposes is the subject of a booklet just issued by the American Lava Company, in which is described the process of converting the mineral talc ($H_2MG_3SI_4O_{12}$) into what is generally known as lava. The talc is machined in its natural chalky condition, and then baked under a temperature of about 2,000deg. F. to a condition of extreme hardness. The material so produced is unaffected by any heat short of this temperature, and is thus available for use in the construction of arc lamps, rheostats, electric heating apparatus, etc. It is absolutely free from metal oxides or other impurities which would impair its insulating value. Changes in atmospheric moisture do not cause it to either swell or shrink, and as its coefficient of expansion with temperature is negligible, it is of special value for instruments requiring a fixed relation of their parts under all conditions. Arc lamp carbon guide bushings are made in

Digitized by Google

thousands according to limit gauges, allowing from but 1½ to less than one-half of 1 per cent. total variation in dimensions. For a kilned product, lava offers unusual advantages in regard to uniformity. Several tests with transformers of large capacity and carefully calibrated electrostatic voltmeters have proved its high dielectric strength, which is calculated at from 75 to 250 volts per thousandth of an inch thickness, depending, as in the case of all insulators, upon the absolute thickness of the sample tested. Compared with mica, it lends itself to a large variety of shapes in which the former cannot be employed. Latterly the cost of lava has been greatly reduced, with the result that it now competes with most of the commoner insulating materials.

Electricity in Textile Mills.—In a paper presented to the New England Cotton Manufacturers' Association, Mr. Chas. Robbins extols the advantages of electrical power for spinning and weaving. It is evident, the author remarks, that an engine or turbine for operating an electric generator will furnish a more uniform and steadier speed than the regular mill engines, and if this uniform speed is available at the spinning frames and looms, an increased production with a more uniform quality of work must result. The author's experience is that electrically-driven mills accomplish this. He further points out that the ideal power plant is one that is so laid out that each unit is working at its maximum efficiency at all times, requires a minimum amount of attendance, occupies the least possible space, and at the same time of such a design that it may readily be extended, and when so enlarged have any or all generating units supplying power to any and all points, irrespective of location of power, demand, or distance. The author states that these conditions are best met by electricity. The alternating-current motor has the widest use in textile mills for the reason that its design is so simple. There are no moving electrical contacts, and as a consequence the only attention required is to keep the motor clean and to properly fill the self-oiling bearings. One of its characteristic features is its automatic regulation, requiring power only in proportion to its output and being capable of sustaining, should occasion demand, large overloads without injury. Owing to the inherent design of this type of motor the uniform rotative speed of the prime mover is available, just as though it were directly geared, and thus a gain in production results from a steady and even speed. The author concludes by eulogising the qualities of the Nernst lamp for illuminating cotton factories.

The Junior Institution of Engineers.—The annual general meeting of this institution was held recently at the Westminster Palace Hotel, when the council's report, balance-sheet, etc., were presented. Good progress was recorded, the membership having risen to nearly 800, and the assets to close on £1,000. Special reference was made to the numerous visits to works which had been made, to the value of the papers read and discussions at the meetings, the conversazione, anniversary dinner, summer meeting in Germany, and other features of activity. Mr. Samuel Cutler, jun., M.I.Mech.E, was re-elected chairman. During the evening two of the past chairmen, Mr. W. J. Tennant and Mr. Percival Marshall, gave an extremely interesting account, illustrated by lantern slides, of their visit to the United States and the St. Louis Exhibition. Another visit occurred on the following Saturday afternoon, when through the kindness of Dr. R. T. Glazebrook, F.R.S, vice-president, an inspection was made of the National Physical Laboratory at Bushy House, Teddington, of which he is the director. For upwards of two hours the members, under his guidance with that of the staff, were kept intensely interested examining and listening to the explanations of the uses and modes of manipulation of the many beautiful instruments and appliances to be seen throughout the various departments of the laboratory, including thermometic, electrical, photometric, metallographic, metrologic, photographic, optical, chemical, and engineering (wind pressure testing, alternative stress testing, insulating material testing, temperature distribution in field coils, etc.). Mr. S. Cutler, jun., in moving a vote of thanks to the director and his staff at the conclusion of the visit, alluded to the great practical utility of the work carried on in the laboratory, which afforded an excellent illustration of the application of science to the solution of the everyday problems which confronted the engineer, chemist, and other commercial men in their work.

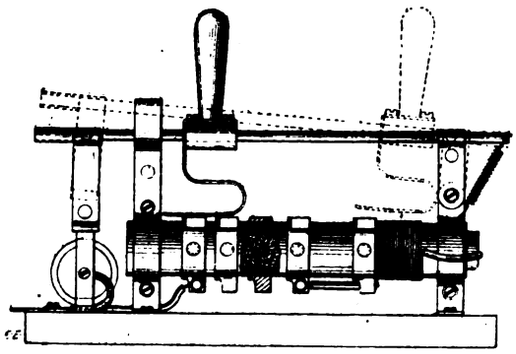
Area of Supply.—The Chancery Division was engaged last week in deciding whether the Metropolitan Electric Supply Company were empowered to supply energy within the urban district of Willesden. From the report of the case given in another column, it will be tolerably obvious that Mr. Justice Farwell's decision in finding that the company possesses no such power was inevitable. The proceedings were nominally instituted at the instance of the Crown, the actuating authority being the Willesden District Council, which holds an order for supplying energy within the district. Under sundry orders the company is vested with power to supply energy in specified areas within the Metropolis, but lack of space in such crowded districts compelled them to seek authority for establishing a generating station at Willesden. The confirmatory Act sanctioning this step conferred no extraneous powers for supplying energy, and any such external supply was expressly vetoed by Section 5 of a special Act passed in 1889, as well as in the company's provisional order. For the purpose of the generating station the company acquired a plot of land at Willesden from the London and North-Western Railway, to whom it has been supplying large quantities of power. The Council were thus threatened with the loss of one of the largest consumers within their district. Counsel on behalf of the company argued that the Electric Lighting Act of 1899, to which the Board of Trade's model provisional order was appended as a schedule, did not contemplate London in the prohibition against supplying energy outside the specified area, and that under its articles of association the company had general powers of supply. The judge, however, had no hesitation in deciding that there was no authority for such a wide interpretation of the company's powers, which he held were restricted to the areas specified in the company's orders. The general question of the advisability of granting undertakers extensive areas of supply on economic grounds is, of course, outside the subject at issue in these proceedings, and Mr. Justice Farwell's view seems to be the only logical one, otherwise the act of the company might create an embarrassing precedent

Fire Precautions on Underground Railways.—The necessity of protecting underground electric railways against fire has been engaging the attention of the Board of Trade and the London County Council. In approving such schemes the Board of Trade will include a direction that efficient hydrants, hose, and fire-prevention appliances shall be provided; and the Board have suggested to the Council that the chief officer of the latter's fire brigade shall certify as to the sufficiency of the apparatus. The Council intimated its willingness to undertake this function if certain minimum requirements and recommendations were laid down, and on the Council's suggestion the Board have adopted the following: "(*a*) A hydrant of the fire brigade pattern to be fitted at each end of each platform, and such hydrant to be provided with sufficient hose and

Digitized by Google

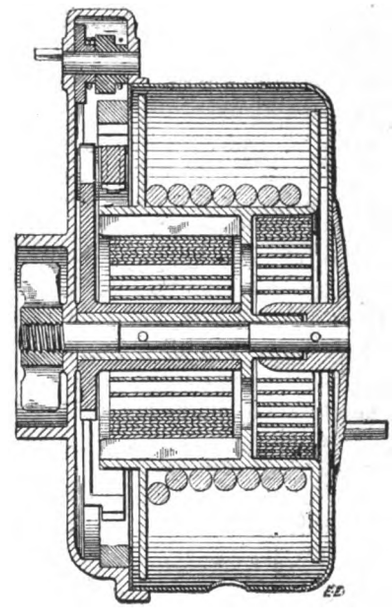
¾in. nozzle to reach the whole length of the platform and of the longest train in use on that particular line; at least six buckets of water and six of sand to be available on each of the several platforms; an extincteur to be supplied to each carriage and to each lift. (*b*) It is recommended that provision should be made for some experienced person responsible to the owners of the railways to periodically inspect and report to the owners on the fire appliances and test the extincteurs, and the owners to be responsible for the good order of all such appliances and for seeing that the railway staff is stationed and drilled; all waste and dirt to be removed at least daily." The recommendations further point out that unless overcrowding in the carriages and lifts is prevented and the gangways of the former kept clear, the extincteurs will probably prove to be useless, and that in the event of fire obtaining any hold in a tube railway the municipal fire brigade would be practically of no avail, so that the railway authorities must rely upon their own resources. The prudence of these measures is obvious, beyond which they will serve to reassure any timorous passengers who, remembering the Paris disaster, still view tube travelling with some apprehension.

Starting Box for Motors.—A patent has recently been obtained in the United States by Mr. J. F. Tracey for a starting box for motors, a description of which, with the accompanying diagram, is given in the *Electrical Review* of New York. The object of the invention is to provide for the automatic movement of the spring contact away from



the plane of the stationary contact plates or prints simultaneous with the reverse movement of the switch arm. The form of starting box consists of a series of contact surfaces formed as a part of and integral with jaws, which pass around a non-conducting tubular support. Within this tubular support is packed a finely-divided conducting material, such as cast iron. The jaws of the contact surfaces are secured in position by means of pins, passing through the wall of the non-conducting tube and through the conducting filling within the same, so that these pins form not only a support for the conducting surfaces, but also electrical connections between the contact surfaces and the finely-divided conducting material of the core. These contact surfaces may be spaced any suitable distance apart according to the amount of resistance desired between adjacent surfaces. The tube carrying the contacting surfaces is secured to a base in any suitable manner, preferably by brackets having semicircular portions embracing the tubes near their ends. The movable contact, made in the form of a spring, is secured to a head, movably mounted on a bar, which is pivotally connected by an arm to one of the brackets. On the free end of the bar is secured the armature of an electromagnet which is designed to be included in the circuit of the field of the motor. When the magnet is excited, the bar will be held in such relation to the contact surfaces that a movement of the sliding head will cause the contact spring to move along and in electrical contact with the surfaces. As soon as the current in the field is reduced or cut off, the magnet becomes de-energised so that the bar is free to be shifted either by its own weight if the starting box is arranged in a vertical position, or by a spring if the starting box is arranged horizontally. By this movement of the bar the latter will assume such an inclined position that the head will slide freely to the lower end of the arm to normal position.

Improved Trolley Retriever.—The *Street Railway Journal* describes a new form of trolley retriever brought out by Mr. C. J. Earll, of New York. This device, as distinct from a trolley catcher, not only checks the upward movement of the trolley when it jumps the wire, but also pulls it down far enough to safely clear the overhead structure. The Earll apparatus was placed on the market nearly three years ago, but the new design embodies several improvements. It is both compact and light, and has a very large rope space. The heavy retriever spring and the light spring which takes up the trolley rope slack are wholly inside the drum. The enclosing case is made up of a malleable iron back and a drawn-steel shell, which fits into a recess in the back, where it is held by the central shaft on which the sheave rotates, being secured by a thumb-nut at the rear, as shown in the accompanying



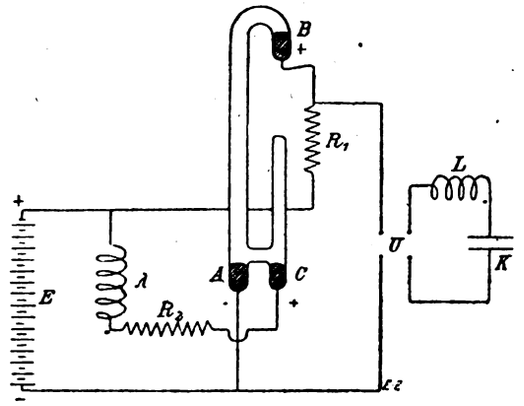
sectional illustration. This thumb-nut is the only screw used in the device. When this nut is taken off, the shaft may be withdrawn and the steel case removed from the back, thus giving access to every part. The drum has a bearing on the shaft 3½in. long, the diameter of the case is 7¾in., and the weight of the retriever 14lb. All of the parts are made of steel except the drum and back, which are of malleable iron. Some diversity of opinion exists as to whether, in resetting the retriever after the pole has jumped the wire, the retriever should be set before replacing the trolley on the wire, whether it should always be set to the same extent, or whether the trolley should be replaced and the car started before setting the retriever. One of the features of Mr. Earll's device is that by merely removing certain parts and substituting others which are interchangeable with them, the retriever can be reset by any of these methods. Where the first is used, it is not necessary to touch any part of the retriever to accomplish the setting, but merely to take hold of the rope. Where the second or third method is employed, the set lever has to be depressed before pulling out the rope. In all three methods of setting, the trolley pole may be pulled down close to the roof of the car before beginning to set, thus enabling the tramway employé to use the up-pull of the trolley pole to assist in

Digitized by Google

setting without danger of carrying the pole high enough to strike the span wires should the car be in motion.

French Municipal Plant.—The electrical plant lately installed for the municipality of Lyons is one of the largest of its type in Europe, the ultimate capacity being 22,000 h.p. Water power is obtained from a neighbouring canal, the available head varying from 33ft. to 40ft., though during extremely high water it drops to 26ft., owing to the rise of water in the tail-race. The canal is 11·6 miles long, 10 miles of which is the head-water canal and 1·6 miles the tail-race. The present equipment consists of eight turbines of 1,250 h.p. each, three of 250 h.p., and two of 1,500 h.p. each. Six additional turbines of 1 500 h.p. each are in process of erection. The power-house is 525ft. long and 50ft. wide, inside dimensions. The canal is led back of the power-house, each turbine being provided with a special tube leading to the turbine chamber, the entering water being controlled by a cylindrical hooded valve 9 9ft. in diameter, which is controlled from the interior of the plant. The portion of the canal at the power-house is built of solid concrete and masonry. The upper part of the building is of brick and the roof is of steel construction with a monitor running the entire length of the building, thus providing ample light and ventilation. The turbines are of the vertical type, and are located on the lowest floor level, the revolving part of the generator being directly connected to the vertical extension of the turbine shaft on the level of the power-house floor. The regulators, bearings, and the oil-pumps are located on an intermediate stage between the turbines and the generators. Each turbine is placed in a separate enclosed chamber, and is readily accessible. The chambers of the 1,250-h.p. turbines are of cast iron. The turbine revolving part is conical in shape, and revolves at a speed of 1,200 revolutions per minute. Each turbine has three divisions, the highest of which is used at times of very high water, this being kept closed by the regulating mechanism at other times. The operation of the divisions is controlled by collars which fit around the circumference of the turbine body, and are movable in a vertical plane by means of rods. The two lower collars are balanced so that the upward movement of one causes the downward movement of the other, and thus the regulating mechanism is relieved of the weight of the shaft and collars. The 250-h.p. turbines are used for driving the exciters. The latest 1,500-h.p. power turbines are of the double-turbine type, which is capable of developing a higher efficiency under the conditions prevailing at this plant, as it has been discovered that the variation in the available head and the frequency of such variation is considerably greater than had at first been expected. The dynamos are three-phase machines, running at 120 revolutions per minute and furnishing current at 3,500 volts. The three machines for furnishing the exciting current are located between the alternators in front of the generator switchboard. These machines are each direct connected to the vertical shaft of a 250-h.p. turbine, and revolve at a speed of 250 revolutions per minute. The generator switchboard contains 19 panels, the three centre ones carrying the measuring instruments for the generators and exciters and the eight panels on either side being for the generators. The switchboard, which is located in a raised gallery, has a steel frame with white marble panels. The switching room is located in an extension of the building in the rear of the board. On a horizontal table in front of the switchboard are the rheostat hand-wheels for controlling the exciter current. In the rear of the building is located the feeder switchboard. The entire power-house is lighted by arc lamps. The turbines were built by Escher and Co., of Zürich, and the dynamos and other electrical machinery by Brown, Boveri, and Co. The turbines, dynamos, motors, and distribution system cost £400,000, and the entire undertaking, including the necessary land and right-of-way, entailed the expenditure of £880,000, the outlay being increased through difficulties with the water supply. The plant is the subject of a descriptive article in the *Electrical World* of New York.

Singing Arc.—The *Electrical World* of New York contains an abstract of an account of an experimental investigation made to examine the theory of Duddell, according to which the fundamental condition to be fulfilled in a singing arc is that dv/di is smaller than zero, where dv is the change of the voltage and di the change of the current in the arc. This condition is fulfilled only with homogeneous carbon, so that if the theory is correct, only an arc between homogeneous carbons could be made to sing. The author has, however, made experiments in which he produced the singing arc with iron electrodes and with mercury electrodes. In the latter case the above differential quotient was presumably positive. His arrangement for the mercury arc is as follows: Since during each oscillation the arc is extinguished, it must be artificially lighted again. For this purpose he makes the cathode of the tested arc at the same time the cathode of a small artificial arc. In the accompanying diagram E is a storage battery, A the



common cathode, B the anode of the main arc, R_1 its regulating resistance, C the anode of the auxiliary arc, R_2 its regulating resistance, U a two-pole switch, L a self-induction, and K the capacity of the condenser circuit. In the circuit of the auxiliary arc a reactance coil is inserted in order to keep the current constant. In the large arc, A B (7in. long), the current was two amperes, the voltage 30; in the small arc, A C, the current was one ampere. Thus Duddell's conclusion has been shown not to agree with the facts. It had been developed mathematically under the supposition that the current is sinusoidal, or what is really the same, that the energy of the oscillations is supplied exclusively from the condenser circuit. But it has been shown that the current wave in the condenser circuit is far from being sinusoidal. The author gives the following theory of the singing arc: If the arc is first burning quietly and self-inductance and condenser are then connected in shunt, the electricity will flow in large quantity to the capacity. If the main current is not strong enough to simultaneously supply the arc and to charge the condenser, the voltage at the arc will decrease. When it becomes smaller than the sum of the cathode drop and anode drop, the current will be extinguished. Then only the single circuit containing the condenser and the battery is left, and the condenser is charged. Now, the voltage at the arc will also increase again, and if the cathode is still hot enough the arc will be started again. The condenser will then be discharged, and so on. The high temperature of the cathode is of great importance.

HADFIELD'S EAST HECLA WORKS, SHEFFIELD.

Since electric traction on tramways came into vogue in this country, many reputations have been won by home firms for sound work, but few have improved upon Continental methods in any direction to the extent that Messrs. Hadfield's Steelfoundry Company, Limited, have done. It seems but a short time since American practice was accepted in this country as a standard. Thanks, however, to the scientific knowledge and commercial ability of a few such men as Mr. R. A. Hadfield, M.I.C.E., the Old Country has shown where improvements could be effected, with the result that much has already been accomplished towards converting our recent lag into a decided lead so far as quality of work and its durability are concerned. The name of Hadfield has become prominent in the tramway world, chiefly on account of its association with special track work. At no time during the development of tramways were engineers more interested in the construction and maintenance of tracks than to-day. The passing of the horse car and the introduction of the electrically-driven car have rendered a

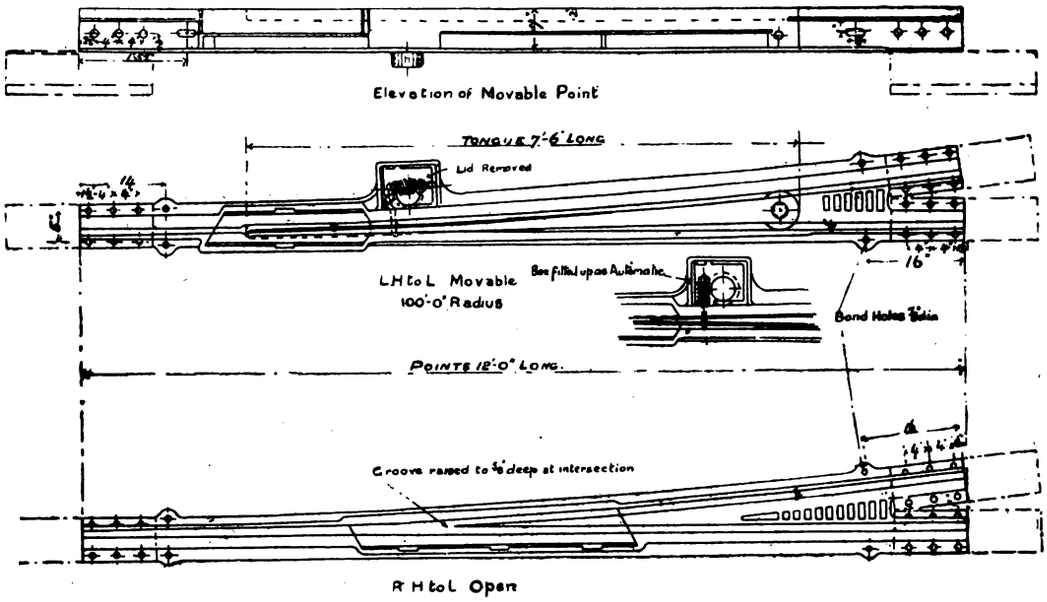

FIG. 1.—Details of Hadfield's Combined Automatic and Moveable Point.

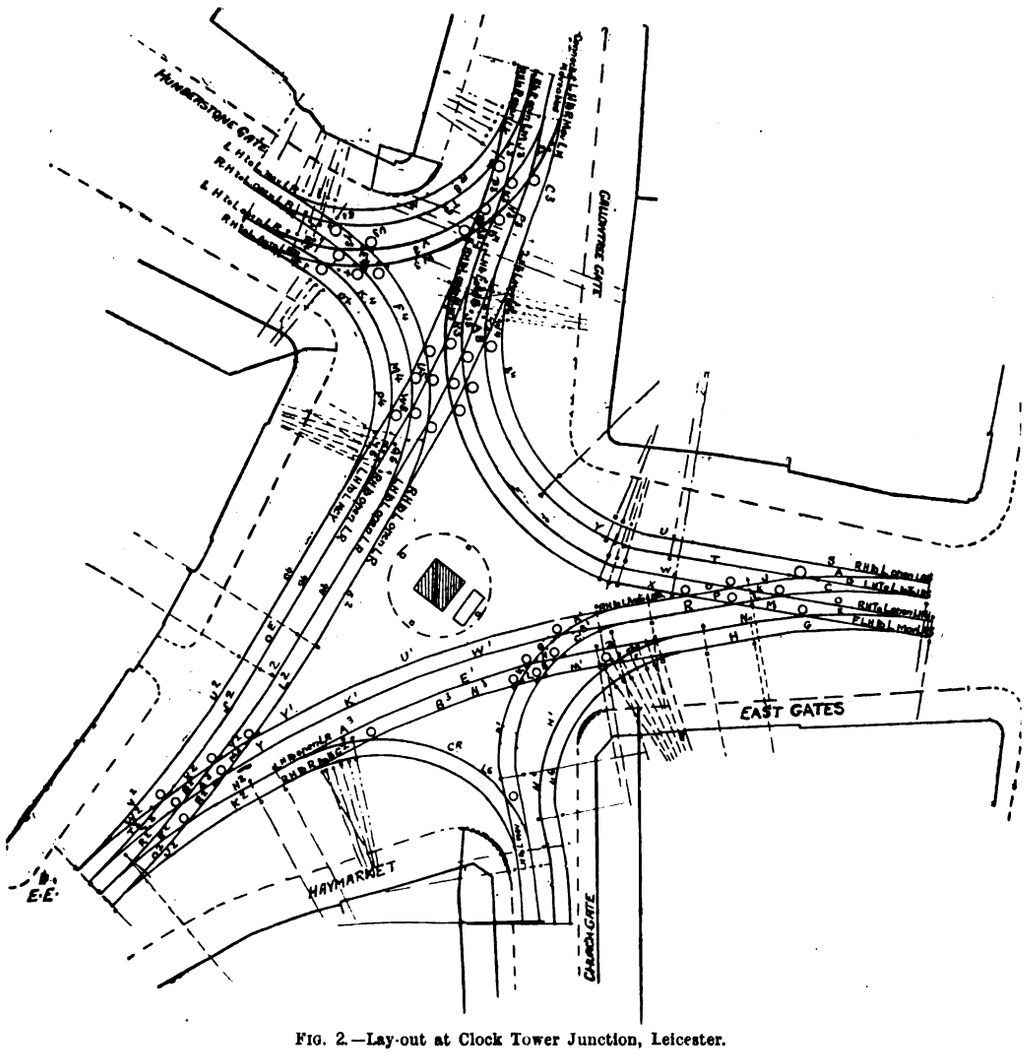

FIG. 2.—Lay-out at Clock Tower Junction, Leicester.

Digitized by Google

reconsideration of the methods of tramway track construction absolutely necessary. In the past, short points of ordinary cast steel were found to be adequate for their purpose, but it has been conclusively shown that under electric traction the wear and tear on the permanent way is much more severe than it was in the case of either horse

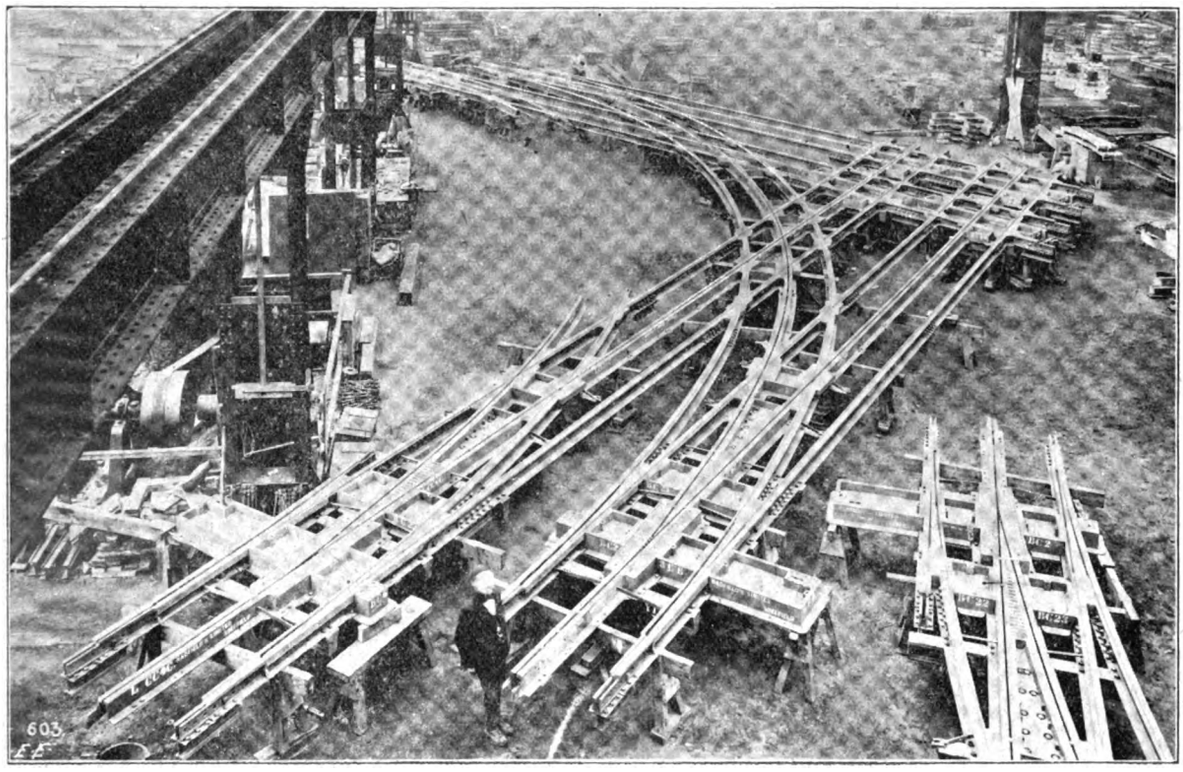

FIG. 3.—Junction for the London County Council Tramways.

or steam cars; more particularly has this been shown in regard to the points, crossings, and special junction work. The higher speeds at which the cars run, the increased weight of the cars, and the heavier loads carried by them, have undoubtedly an important bearing upon the reduced life of the permanent way. Bearing in mind the altered conditions, it is satisfactory to know that a firm of British manufacturers have risen to the occasion, and are in position to supply a material which for resistance to wear and tear is inferior to none on the market to-day. We refer to the Hadfield Company's patent "Era" manganese steel, which combines great hardness and toughness with high tensile strength, the two first-mentioned qualities being so pronounced that the best tool steel cannot machine it. At the same time the material is not brittle in any sense of the word, but, on the contrary, can be bent cold without showing any sign of fracture. It is not, therefore, surprising that engineers responsible for the maintenance of tramway tracks should have recognised in "Era" manganese steel a material for points and crossings which is calculated to give the maximum of wear at a low ultimate cost.

In addition to making points and crossings of this special steel, the firm have also supplied large numbers of "Era" manganese steel rails for use on sharp curves. Amongst the users of this type of curved rail are the Liverpool, Bradford, Bournemouth, and Sheffield Corporations; in fact, whole junctions, including not only points and crossings but also straight and curved rails of this steel, are in extensive use on tramways throughout the country. They also manufacture toughened cast-steel points and crossings either with or without "Era" inserts, the former, to meet modern requirements, being supplied of any length up to

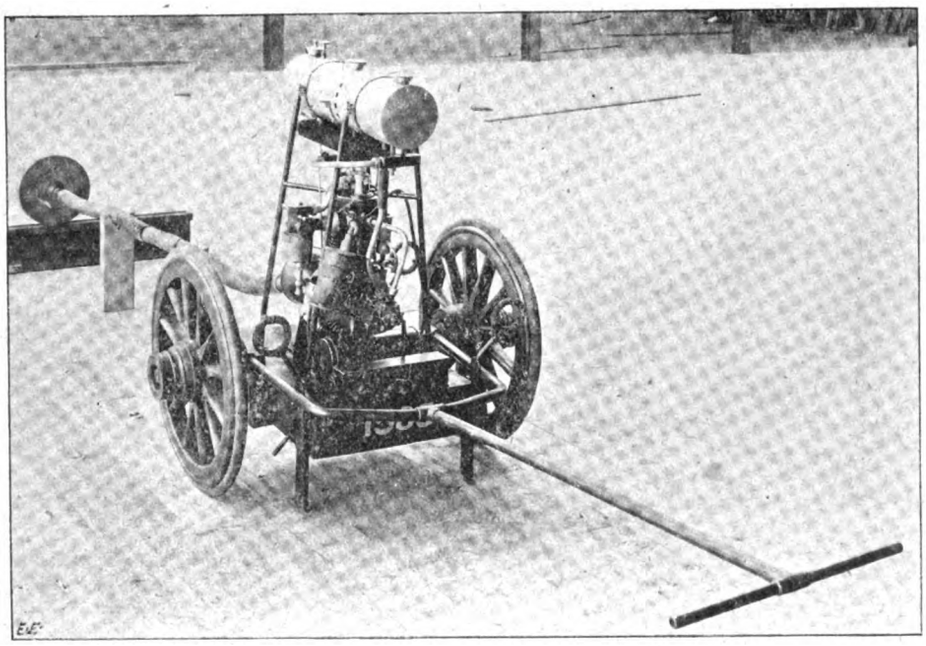

FIG. 4.—Hadfield's Motor Emery Grinding Machine.

Digitized by Google

15ft. It is noteworthy that the company have made the longest tramway casting in Great Britain.

Their improved patent combined automatic and movable point (of which details are shown in Fig. 1 herewith) has found considerable favour. Referring to the illustration, it will be seen that this point is so designed that it can be converted from an automatic pulling or pushing point into a movable one, or *vice versâ*. The necessary alteration can be carried out by an ordinary platelayer in a few minutes without interfering with the permanent way or delaying the traffic. The whole of the mechanism is contained in a box at the side of the point, and is kept as near the top as possible, so as to be free from accumulations of dirt, etc. Under their patent the firm also supply either the frog or leg type of crossing, with or without inserts, as well as the cast-iron bound type with "Era" manganese steel inserts.

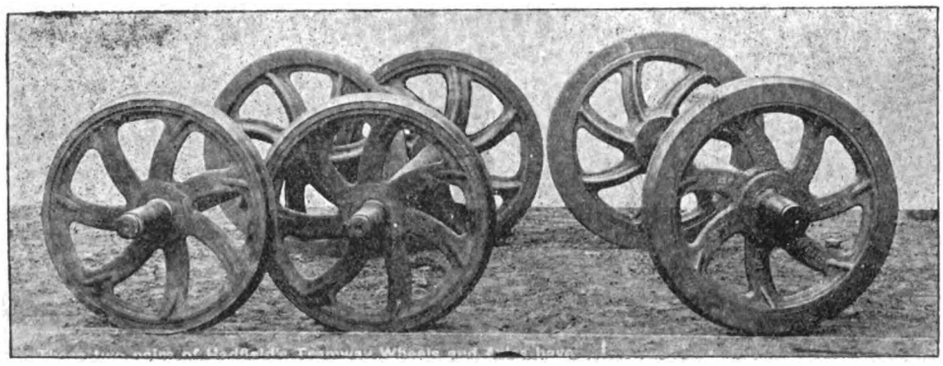

FIG. 5.—Hadfield's Steel-Tyred Car Wheels, showing wear after 2¼ years' service and a total mileage of 79,680.

A recent visit to Messrs. Hadfield's East Hecla Works, Sheffield, enabled us to fully appreciate the splendid facilities with which the company have provided themselves in this department. The old method of constructing special work on site, with its consequent serious inconvenience to the general public, through the street excavations being unduly prolonged, is no longer continued, since electric traction has rendered absolute accuracy essential to success, and this can only be obtained by the exercise of the greatest care, in which the time factor, of course, plays an important part. We believe Messrs. Hadfield's were the first firm in this country to meet the new conditions. They constructed a setting-out floor, and adjoining it is a lay-out yard six acres in extent, equipped with modern electrically-driven machine tools for bending, sawing, and drilling rails. Here we saw a great variety of special work for railways, tramways, and docks in progress. The company undertake full responsibility in connection with all special work entrusted to them for construction. To facilitate the easy running of cars they have adopted, as the result of considerable experience and research, "standard spiral" or "easement" curves, which are introduced wherever possible.

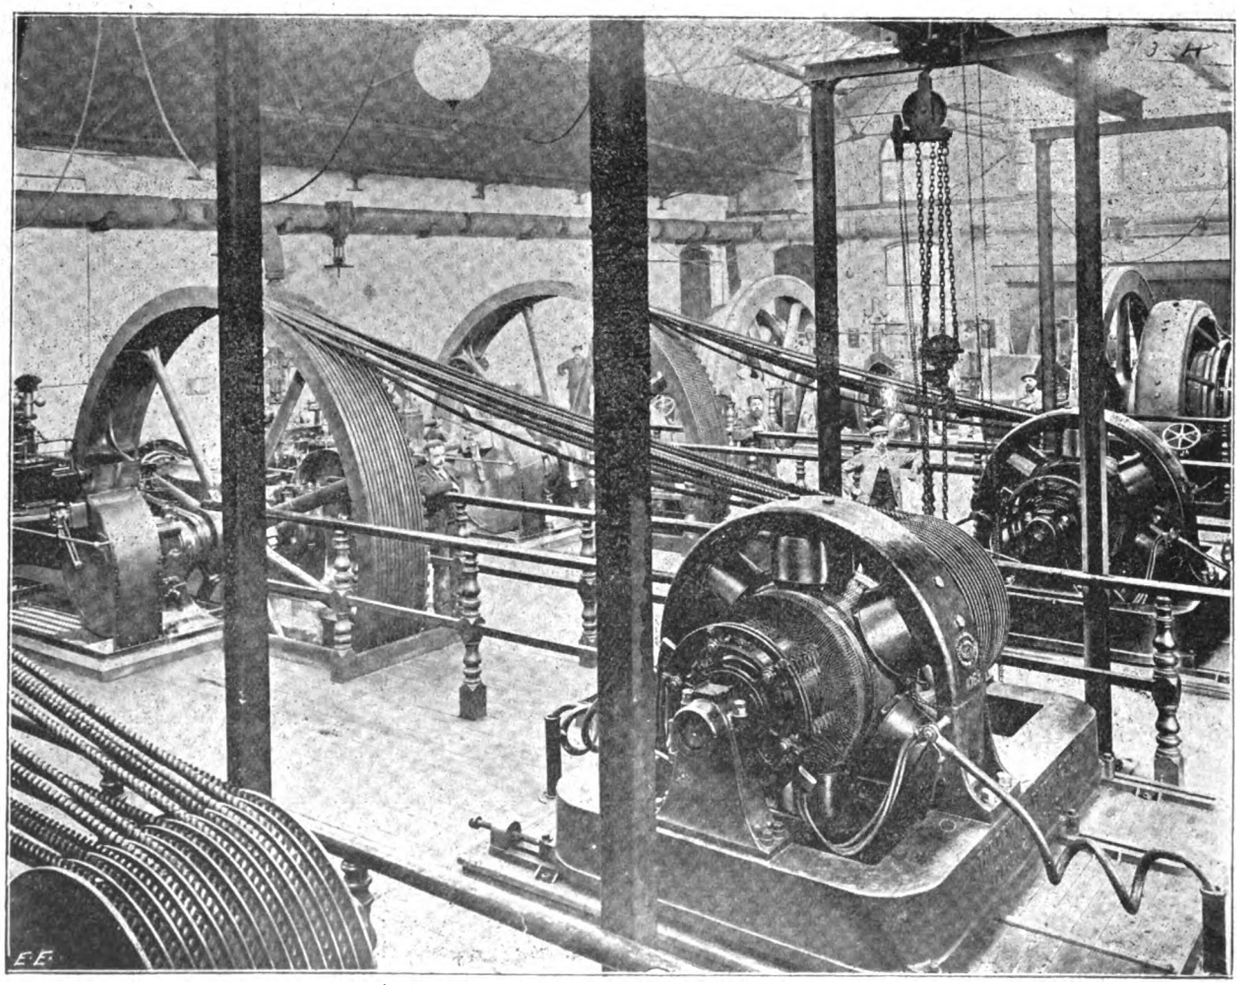

FIG. 6.—Interior View of Power House, Hadfield's East Hecla Works.

Of the vast amount of special track work recently carried out by the firm, that in connection with the Leicester Corporation tramways deserves particular mention, since it included the now famous clock tower junction, which claims the distinction of being the largest lay-out in the

Digitized by Google

country. The total weight was over 100 tons, and it was laid by the Corporation's own staff in 10 days—a fact which speaks well for the accuracy of the parts. From the illustration (Fig. 2) it will be seen that this lay-out comprises no less than 10 running tracks.

that the second contract was divided, half going to America and half to Sheffield, and although the English firm had to instal a number of large machines to cope with the work, it is satisfactory to note that their contract was completed a fortnight within the specified time. Since then they have

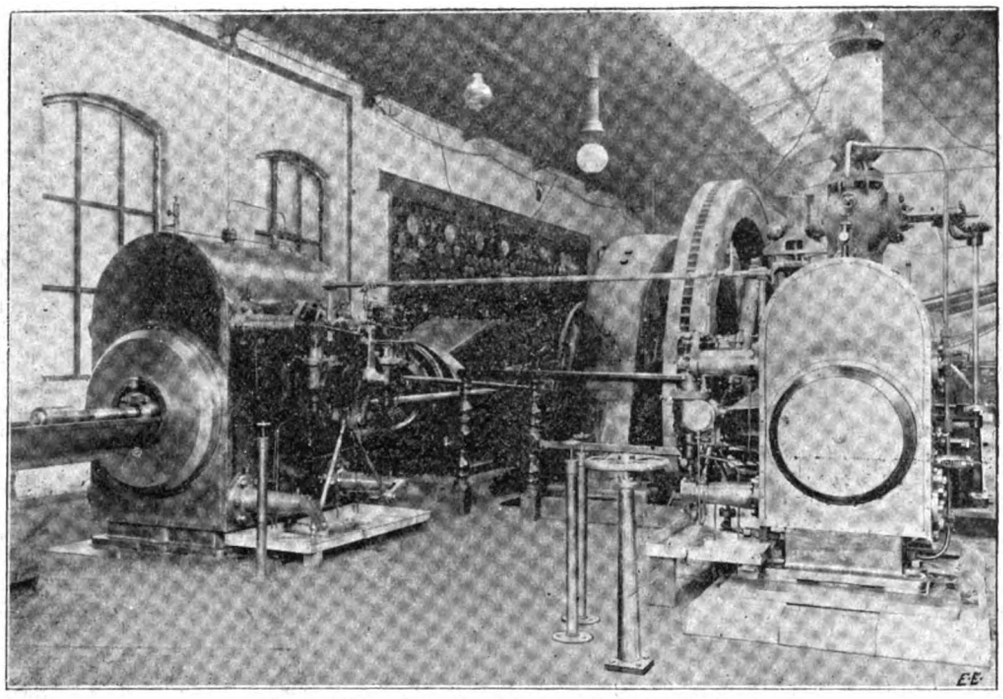

FIG. 7.—300-kw. Generating Set, Hadfield's East Hecla Works.

As specialists in the construction of the complicated lay-outs incidental to electric conduit tramways, Messrs. Hadfield's have also had considerable experience. Their first contract in this particular line was for the Bournemouth Corporation tramways, the points and crossings for both trolley and conduit lines being made of "Era" manganese steel. When the first special work contract for the new lines of the London County Council was issued, no firm in this country would undertake to complete in the time specified, wherefore the order was sent to America. On the next occasion Messrs. Hadfield's, who had prepared meanwhile, entered into the competition with the result obtained and successfully executed two further orders for the same authority. The accompanying illustration (Fig. 3) shows a junction, included in one of their orders, erected at the works before being dispatched.

There is no need to enumerate the tramways in connection with which this enterprising firm have constructed special work. Suffice it to say the list would be lengthy, and include most of the important undertakings throughout the country. At the time of our visit the lay-out floor was covered with work for Johannesburg, Erith, Exeter, and Chesterfield, among other places more or less remote from each other.

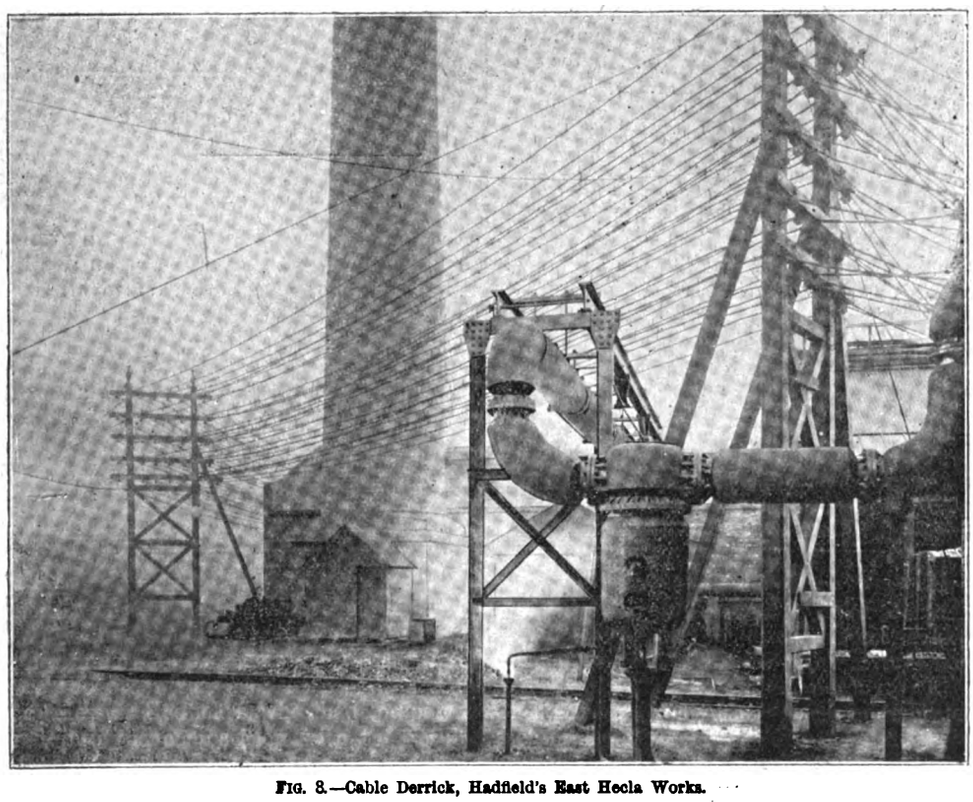

FIG. 8.—Cable Derrick, Hadfield's East Hecla Works.

While on the subject of special track work, brief reference may be made to an interesting grinding machine designed and manufactured by Messrs. Hadfield's. This machine (Fig. 4) enables the groove and tread of tramway track work to be ground after having been fixed in position without interfering with the running of the cars. It is especially useful where "Era" manganese steel has been used, as this material cannot be machined in the ordinary way. The grinder is furnished with a petrol motor of 3½ b.h.p., with water-cooled head, the water being circulated by means of a small pump attached to one end of the motor shaft. The motor is fitted with electric ignition. The emery wheel is connected with the motor by means of a flexible shaft and universal joint. It is claimed that this machine has an advantage over the electrically-driven type of grinder, in that it does not require any outside source of power to work it.

Messrs. Hadfield's have also specialised the design and manufacture of steel-tyred wheels for electric street cars.

Fig. 5 illustrates a set of wheels which have been used in regular service for 2½ years in Sheffield, where, owing to the hilly nature of the district and numerous short curves, the working conditions are exceptionally severe. The total mileage covered by the wheels shown on the left in the illustration was 79,680, and we understand this type of wheel has been found to be much more economical in working than the ordinary chilled wheel. With regard to the construction of these wheels, it may be said that they are formed by a centre made of best toughened cast steel, on which is fitted a rolled tyre of a specially hard and tough grade of steel, which, being homogeneous in its composition, ensures regular wear. As a consequence, they preserve their circularity, and will run smooth till the last, not, therefore, requiring to be trued. Large numbers of these wheels are being turned out to meet a growing demand. In another department we noticed a number of castings for electrical machinery, including magnet rings 16ft. in diameter, and weighing 20 tons each, besides numerous smaller sizes. The East Hecla establishment is exceptionally fitted for this class of work, possessing as it does what is claimed to be the largest foundry in the world. This foundry is a sight worth seeing. It is of huge dimensions, being served throughout by electrically-driven cranes of various types and powers.

In the foregoing we have touched upon such only of Messrs. Hadfield's specialities as concern our readers—a comparatively small part of the whole, in fact. Naturally the supply of power is no small item in a works of this description. All the machine tools are electrically driven. The power is taken from a central station which is equipped with five generating sets—three of 160 kw. output and two of 300 kw. output each. Fig. 6 is a general view of the plant. These generators produce continuous current at 230 volts, and the current is used at this pressure for both power and lighting. The switchboard is divided into five panels, with the necessary main switches, regulating resistances, main ammeter, and voltmeter for each generator, all being arranged for parallel running. The main distribution leads are taken from the 'bus bars, and for each main lead a circuit breaker is provided, together with an ammeter, so that each distributor can be cut out from the switchboard, and the amount of current passing through the individual distributors observed. The three 160-kw. generators are rope-driven by cross-compound Corliss engines having cylinders 17in. and 28in. diameter by 3ft. stroke, running at 90 revolutions per minute. The rope flywheels are 15ft. diameter, and drive the generators at 400 revolutions per minute. The two 300-kw. sets, on the other hand, are direct driven by cross-compound engines having cylinders 20in. and 36in. diameter and 36in. stroke, running at 100 revolutions per minute, the armature being carried on the crankshaft between the cylinders. One of these sets is shown in position in Fig. 7. The last of the accompanying illustrations (Fig. 8) shows one of the cable derricks outside the generating station, and will give an idea of the extensive system of cables used throughout the works.

In conclusion, we have to thank Messrs. Hadfield's for the assistance they have given us preparing the above article.

NOTES ON MOTOR-STARTING SWITCHES.

[CONTRIBUTED.]

(Continued from page 625.)

The solenoidal switches are the most interesting to study, and the various combinations which can be devised with this type are endless, and so adapt this pattern of starting switch for any purpose. In the description which has been given of the general type of solenoidal starter, it would be noted that all the parts are open, and are therefore liable to be tampered with; the apparatus is one of great utility, but it is intricate, and requires a certain amount of attention. The same makers have another pattern, which is shown in Fig. 7, and which they term a "full-proof" starter. This switch, if well made, fulfils all the requirements of a good starter, and is suitable for any circuit, as the whole of the switch, with the exception of one handle and a push button, are enclosed in an iron case. The advantages claimed for this switch may be summarised as follows: (1) The operator starts the motor by one movement of the handle; at the same time only a slow motion of the contact lever is possible, its speed being regulated by a dashpot, which is not under the control of the operator. (2) The main switch is interlocked electrically with the rheostat arm, and cannot be closed until all the resistance is cut out of circuit. (3) A maximum and minimum circuit breaker of simple construction are contained in the switch, one of which comes into operation either with an overload or with an interruption of the current. The circuit breaker

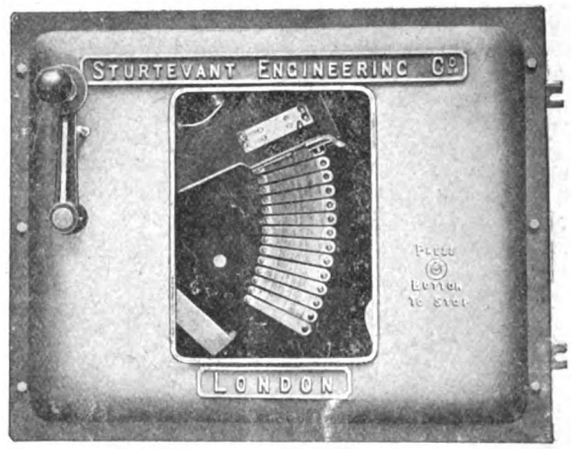

FIG. 7.

having been opened from either an overload or interruption, it cannot be closed again until all the resistance is reinserted. (4) The circuit is invariably broken by the circuit breaker, and never under any circumstance by the contact lever; hence there is no sparking at the contacts, with consequent sparking. (5) The circuit breaker is fitted with carbon points, and for large sizes magnetic blow-outs are also included, so that an arc cannot be maintained. (6) The motor can be stopped at any time, either before or after it has attained its normal speed, by simply pressing a push button or by reversing the starting handle, and in either case the circuit is still broken at the circuit breaker. If to these conditions it is seen that the resistance is of the proper section and well mounted so as to eliminate any fear of undue temperature rise or danger of sagging, it will be seen that the switch answers all requirements, while at the same time it is an instrument which is little likely to get out of order, and can be operated by any fairly intelligent man. Being well enclosed, it can also be erected in more or less exposed positions.

The description of the construction of this switch willl show how the various conditions are attained. The main switch or circuit breaker, which is mounted on the upper right-hand side of the slate, is controlled by a powerful solenoid, and is also fitted with heavy carbon contacts for making and breaking the circuit, and with laminated phosphor-bronze brushes for carrying the current continuously. On the left-hand side of the slate is an ordinary motor-starting switch, having its contact lever arranged so

Digitized by Google

as to fall by the action of gravity, and cut the resistance out of the motor circuit, unless held in the position of all resistance in by the small detent in the upper portion of the slate. A second lever attached to the operating handle is used to lift up the contact lever to its highest position, when it engages with the detent mentioned. On the side of the rheostat contact lever is mounted a short-circuited piece, which bridges two contacts when the contact lever is in its highest position. A similar bridging piece is mounted on the tail of the operating lever, this being used to bridge another two contacts when the operating handle is in its position for starting the motor. It is necessary that both these two sets of contacts should be bridged to complete the solenoid circuit of the main switch. When this solenoid circuit is completed the main switch closes, and in closing trips the detent which held the contact lever in its highest position, thereby allowing the latter to fall and cut out the resistance from the motor, circuit, the speed at which the contact lever falls being controlled by an adjustable dash-pot. When the contact lever leaves the highest position it disconnects the two contacts in the main switch solenoid circuit, which were previously bridged by the contact strip attached to it. The main switch solenoid circuit then remains completed through the bridge piece carried on the tail of the operating lever, and through the main switch itself; consequently, if the current supply fails, or if the operating handle is moved back ever so little, the main switch opens and cannot be again closed except by bringing the operating handle back to its full extent, so as to lift the contact lever to the highest position, and then bringing the operating handle forward to the running position. On the lower right-hand corner of the slate a small electromagnet is mounted, having an adjustable armature, which, when lifted by the magnet, opens a carbon-tipped switch which is in the solenoid circuit of the main switch, and hence causes the main switch to open. The winding of this magnet is connected in the main motor circuit, and the armature can be adjusted so that it will lift and stop the motor at any desired overload. An external resistance, which may take the form of lamps, is also included, and are usually inserted into the main switch solenoid circuit as soon as the main switch is closed, thereby reducing the current consumed to a minimum. A small push button is mounted on the case, which, when pressed, lifts the armature of the overload magnet, and so causes the main switch to open.

From the above description it is apparent that it is quite impossible for the operator to use this switch in an improper manner. There is only one handle accessible, which normally would be in a horizontal position. To start the motor it is necessary to bring the handle to a vertical position, where it is held by a spring catch; after this the whole operation of starting the motor is performed automatically by the starting switch. If the operator, instead of bringing the handle to a full vertical position, moves it only to an intermediate position, the main switch will not close; or if after bringing the handle to the correct position he moves it back, with the apparent intention of preventing the contact lever from cutting out the whole of the resistance, the main switch will immediately open, and the whole operation of starting must be commenced *de novo*.

It is unnecessary to explain that switches of this type are more expensive, if we only consider first cost, than are the more ordinary types complete with no-volt release and overload preventers commonly met with. The question, however, arises, what is meant by the word expensive? If account is taken of the life of the switch, and, above all, of the motor which the switch is intended not only to control, but also to protect, then there is no doubt that these higher-priced switches are not so expensive as are the lower-priced ones. The user has three things to consider in making up his accounts: the first is the interest on the money laid out on the installation; secondly, the running cost of the plant; and, thirdly, the cost of upkeep and repairs. It may be urged that he can insure the whole of his electrical plant, dynamo, motors, and controllers against breakdown, and that the various insurance companies will quote no lesser rate because he has adopted the most elaborate controlling switches that he could find, and that as they pay all costs of repairs it is unnecessary to protect them against breakdown by spending more money than is absolutely essential on the installation. This argument is fallacious, for it overlooks the fact that although the insured is reimbursed the amount the repairs cost, he is not compensated for the loss in profits caused by the stoppage of the motor consequent on the breakdown. Even assuming that he were compensated at the rate of some agreed upon sum for each day the motor was stopped, unless this amount were large he might still be a loser. Suppose that he were manufacturing in the machine driven by the motor goods under penalty, the loss both in money and prestige might be very great. The principal object of insurance appears to be the periodical inspection of the whole plant by independent experts, who while independent have a serious stake in the upkeep of the machine, amply sufficient to prevent their inspections being of a perfunctory character. It is still to the benefit of the insured to adopt any reasonable suggestion for the better welfare of the plant. If only persons considering the question of adopting motor installations could be persuaded generally to have the scheme prepared and the work carried out under expert advice, a better class of starting switch would undoubtedly become more general; but the writer is also convinced that if contractors would give alternative estimates—one for the work with the ordinary controlling appliances, and a second for the same work with the best class of starting switches—and at the same time distinctly and briefly state the advantages accruing from the use of the best type, a general advance would be made. This would be to the benefit of the motor manufacturer and to the purchaser, while at the same time the contractor would participate in the good result, for he would establish a reputation for sound and good work, while at the same time he would make a decent profit on each transaction, for it is a well-known fact that cheap jobs leave but little margin to the contractor, while on good contracts a fair profit is assured.

There is every reason to press for improvement in the controlling devices when so many good motors annually break down owing to defective starting switches. We have seen that Mr. Gibbings, when borough electrical engineer of Bradford, was compelled to design an improved starting switch, as the number of breakdowns to motors hired out by his Corporation, and which were directly due to poor starters, was so very great. In a similar manner, if we turn to the reports of the various insurance companies undertaking this class of risk, we find they state that the number of breakdowns per annum is equal to one machine in nine, and one machine in seven of those insured. It must also be borne in mind that these machines insured are not old and obsolete machines, but good machines, as the companies do not accept indiscriminately for insurance every machine proposed, but that it is first examined by one of their inspectors, and his report considered by a trained electrical engineer in the office; further, the insured machines are also periodically inspected several times a year, and every means is taken by the company to see that it receives proper attention. The large number of breakdowns then assumes a serious aspect, especially when it is stated that the majority of the breakdowns occur to motors, and that the two principal causes are dirt and *inadequate and defective starting switches*. When the number of failures in ordinary work is compared to the number of failures in connection with motor-driven printing presses, and which are fitted with the best types of controllers possible to obtain, the case in favour of using a better class of starting switch generally in order to obtain the highest economy is fully proved.

The starting switches so far dealt with have all been for non-reversible motors, but as the general practice is now to adopt electrical driving for all classes of hoist work, whether for a passenger hoist, a goods lift, or crane work, reversible motors are necessary, and the starting switches must be designed to give perfect control under all conditions. For cranes it is customary to instal either three or four motors, depending upon the size of the crane. In small cranes there is generally a separate crane motor for hoisting, longitudinal travel, and cross traverse, while in larger sizes there may be a fourth motor for slewing; these motors are generally series wound. For lift work the motor is generally shunt

Digitized by Google

wound, and two different systems may be adopted. In the first place, the motor may be non-reversible, and the hoist worked off crossed and open belts. This system is frequently met with in connection with good hoists in warehouses, etc, but this system is never met with in passenger hoists. Here the motor is controlled from the cage, and it is made of the reversible type. The same type of motor is also now being more frequently adopted for good hoists, the only difference being that the motor must be controlled from each separate floor. If only one controlling point situated close to the hoist is required on each floor, then the arrangement is very similar to that required for the passenger hoist; but at times several controlling points are required, and while each of these must be independent, it is also requisite that two different motions cannot be given to the cage at the same time. All these different requirements mean different types of starting switches.

In the reversible motor the shunt current always flows in the same direction, and the different directions of the motor are attained by reversing the direction of the current through the armature. When the current is reversed in direction through the armature, the same precautions must be taken as in the case of starting a motor from rest. The stoppage of the current must first bring the armature to rest so that no current passes through it in the reverse direction until it is so at rest, as the mere stoppage of the current would not bring it to rest immediately owing to the mechanical inertia. It is usual to fit the winding drum with some form of strong magnetic brake. This should be actuated by the main current if the shunt is maintained excited during the operation of reversal, but as it is customary to entirely disconnect the motor from the supply feeders at this period—that is, to break both shunt and armature circuits at each reversal—it is more customary to insert the magnetic brake circuit in the shunt circuit. As soon as the current commences to flow through the shunt the solenoid controlling the magnetic brake is energised, and the brake slipper is lifted off the drum, and the motor is free to revolve in either direction, while conversely, as soon as the shunt current is broken, the solenoid is de-energised, and the brake is applied. This magnetic brake, especially in the case of passenger hoists, should be effective and reliable, as upon its action depends not only the life of the motor, but also the safety of the passengers, and the successful working of the hoist.

In all starting switches for reversible motors which are controlled from the cage, a rope pulley is fixed to the spindle operating the lever. The pulley and rope are so arranged that the rope can only be moved a certain distance in either direction. When it is pulled to its full extent in one direction the cage will move upwards, when to its full extent in the other the cage moves downwards, while the intermediate position brings the motor to rest. In reversing the direction of the cage, the rope must be pulled past this intermediate position, and the starting switch, acting in conjunction with the magnetic brake, must be designed so that under every circumstance the motor is stopped as the rope is pulled past this point.

(To be continued.)

THE MEASUREMENT OF THE POTENTIAL OF THE ELECTRODES IN STATIONARY LIQUIDS. THE DETERMINATION OF CHANGES OF CONCENTRATION AT THE CATHODE DURING ELECTROLYSIS.*

BY HENRY J. S. SAND, PH.D., M.SC.

In recent electro-chemical investigations accurate data are, as a rule, to be found regarding current density, voltage, temperature, and concentration of liquid taken, and very often also regarding the potential of one of the electrodes, defined as the drop of potential on the boundary between it and the electrolyte. The actual concentration of the electrolyte in contact with the electrode, is, however, very often uncertain, owing to the removal of substance by electrolysis. Some years ago I was able to demonstrate the great importance of this factor in connection with the electrolysis of acid solutions of copper sulphate. When small current densities were employed in a stationary solution, it was possible to show with a fair amount of accuracy that evolution of hydrogen only took place after the complete removal of copper salt from the liquid in contact with the electrode. On the other hand, when large current densities were employed, this local depletion took place so rapidly that even the most vigorous stirring could not prevent it. The result obtained in this research could be predicted theoretically when the assumption was made that the process occurring at the electrode itself was of a reversible nature—that is, that on the boundary between electrode and electrolyte, chemical equilibrium must be supposed to remain continually established. The matter may also be stated in the following manner corresponding to a form in which it has recently been put forward by Nernst as a general principle: Differences of chemical potential cannot exist for a finite period of time on the boundary of two phases—that is "between infinitely near points"—as this would lead to infinitely great forces and reaction velocities. According to this assumption the actual velocities of electro-chemical reactions, and of all others which occur on the boundary of two phases, are infinitely great as soon as conditions of equilibrium have been overstepped by a finite amount, the observed velocities being simply limited by the rate with which diffusion and convection renew the material removed by the reaction. As conditions of equilibrium in electro-chemical reactions are determined by the electrode potential, by which name I propose to indicate the drop of E.M.F. on the boundary between electrode and electrolyte, and the rate of these reactions is proportional to the current strength, this may be expressed in the following manner: "When the electrode potential at which a reaction begins has been exceeded by a finite amount, the current strength becomes independent of it, being only limited by the velocity of convection and diffusion. The instance just referred to of the deposition of copper conforms to this rule, for it seems very probable that when a sufficient drop of potential is maintained on the boundary between electrode and electrolyte, the rate of deposition of copper only depends on the rate of renewal of the metal salt at the electrode. Examples of a similar kind have been studied by Brunner—viz., the rate of reduction of iodine to hydriodic acid with definite cathode potentials and the rate of liberation of hydrogen from weak solutions of acids under similar conditions.

As has already been indicated, Nernst and Brunner are plainly of opinion that all cases of electro-chemical action may be ultimately considered from the same point of view. It is not the object of the present paper to enter very fully into a thermodynamical discussion of the principle involved. It will suffice to point out that the latter seems sufficiently invalidated for *a priori* application to actual cases owing to the impossibility of stating that the atoms chemically reacting on the boundary of two phases are in infinite proximity. In fact, the results of several recent researches, notably those of Haber, stand in opposition to conclusions drawn from the principle under discussion. The object of all these researches is the investigation of the dependence of electro-potential as defined above on current density. In Haber's work the reduction of nitrobenzene is examined, but instead of finding the current density to be independent of the potential of the cathode, his results point to a logarithmic dependence of the latter on the former. In fact, he has partially explained his results, starting from the not improbable assumption that the variations of potential are brought about by the absorption in varying concentrations of hydrogen, or other reducing material, by the electrode. In the further elaboration of this view his results may all be foretold if we adopt as an empirical fact that the velocity of reduction at the electrode, v, depends on the concentration of hydrogen, c, in it according to the relation

$$v = \kappa c^{\gamma}$$

in which κ and γ are constants depending on the conditions of the experiments. In contradiction to this, as will be understood from what has already been said, Nernst's view

* Paper read before the Faraday Society, Oct. 25, 1904.

Digitized by Google

would require that once the conditions of equilibrium have been overstepped, the above velocity should be infinitely great. As a matter of fact, Haber's results have been doubted by Brunner, who believes that changes of concentration in the liquid adjoining the electrode may be partly responsible for them. To this Haber and Russ have replied, stating reasons for the correctness of the results obtained by the former. In view of the fact that the investigation of the dependence of electrode potentials on current density seems one of the most important problems of contemporary electro-chemical research, its appears very desirable to have independent methods for the determination of the rate at which changes of concentration occur in the layer of electrolyte adjoining the electrode.

When the diffusion coefficients required for calculating these changes of concentration are not known, it would seem that the most reliable method for arriving at an estimation of their rapidity is afforded by the investigation

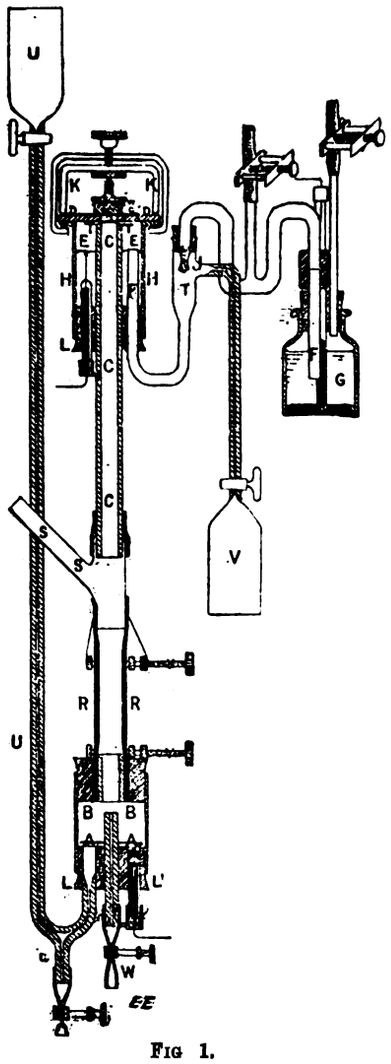

FIG 1.

of the behaviour of stationary liquids free from convection currents. This was the method adopted by me for the examination of copper solutions. When hydrogen began to be evolved owing to complete depletion of the copper-salt at the electrode, a sudden, very large fall of cathode potential took place, which caused a corresponding increase of voltage between the two electrodes that could be easily observed. This method is only applicable where very sharp breaks of potential occur, and the anode is not polarisable in the liquid employed. Another method has since been described by Cottrell. In it a constant E.M.F. is maintained between the electrodes; the current, however, must remain so minute, or the resistance of the electrolyte be so small, that practically no E.M.F. is required to overcome it according to Ohm's law.

It is the object of the present paper to describe a method which will allow the electrode potential in stationary liquids of the most varying kind to be measured, when very much larger currents are employed than those which can be made use of according to Cottrell's method, and at the same time to indicate the nature and the scope of the conclusions that can be drawn from the results obtained.

DESCRIPTION OF APPARATUS AND ELECTRICAL ARRANGEMENTS.

It was necessary that the apparatus should fulfil the following conditions: (1) The electrode under examination must be placed horizontally either at the top or at the bottom of the apparatus. It should be readily interchangeable and accessible to observation during an experiment, and allow the current to have uniform density. (2) The electrode not under examination should be as non-polarisable as possible, and no gases must be evolved which might stir the liquid. (3) The difference of potential between the electrode and the layer of electrolyte in contact with it must be capable of continuous measurement during the course of an experiment. (4) It was found desirable to have the apparatus arranged so that several successive

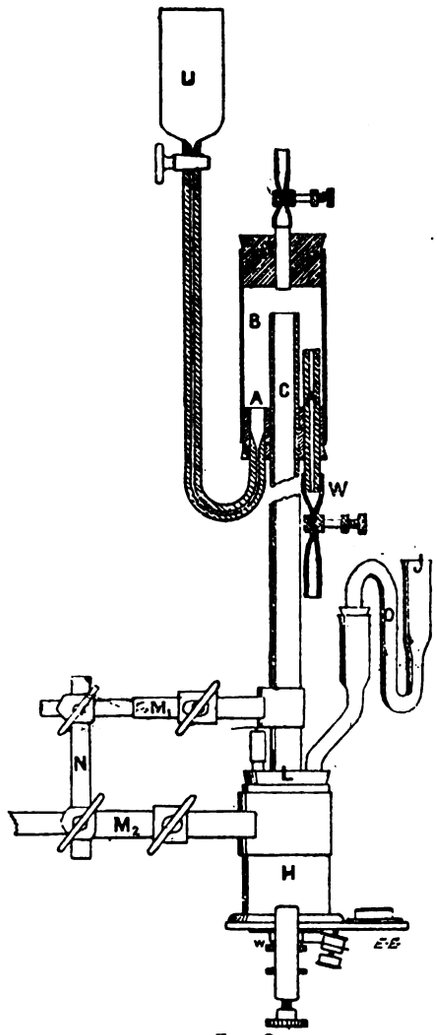

FIG. 2.

determinations could be carried out without taking it to pieces.

Figs. 1 and 2 serve to illustrate the apparatus that was designed to meet these requirements. For the sake of brevity we shall call the electrode under observation the cathode, the other electrode through which the working current enters or leaves the liquid the anode, although there is no reason why our cathode should not be used as anode and *vice versâ*. Making use of these abbreviations, Fig. 1 shows the apparatus with the cathode at the top, that is for liquids that become specifically lighter during electrolysis. In Fig. 2 the cathode is at the bottom, as used for liquids that become specifically heavier during electrolysis. The positions of the anode are indicated in both figures by A. The current passes up the wide tube, B, and then enters the long straight tube, C, of about 1cm. bore. The cathode is approached through a hole, D, in the glass plate, D (as shown in Fig. 1). The E.M.F. between the cathode and the part of the electrolyte on the other

Digitized by Google

side of the glass plate, D, is determined, a liquid connection being tapped off here through the annular space, E, and the tubes, F, to the non-polarisable standard electrode, G. We shall indicate by T the place in the electrolyte between the glass plate, D, and the tube, C, where the liquid connection is tapped off to the standard electrode. The E.M.F. actually measured on the potentiometer is that between the cathode and the standard electrode, and this is composed of the following parts: (1) the drop of E.M.F. due to polarisation between the cathode and the layer of liquid in contact with it; (2) the difference of potential between the cathode and T, calculated according to Ohm's law as the product of the resistance between the two and the current strength; (3) any small E.M.F. brought about by contact of the electrolyte examined with the decinormal potassium chloride solution of the standard electrode; (4) the constant E.M.F. of the standard electrode.

The first of these quantities is the one which it is desired to measure; the third was always assumed to be zero, as has been done by other investigators. The fourth may be taken, according to Ostwald and Wilsmore, to be 0·615 volts for the standard so-called decinormal electrode composed of mercury in contact with a decinormal solution of potassium chloride saturated with mercurous chloride. Being constant for all experiments, it need, however, not be taken into consideration. The second difference of potential mentioned may, as a rule, be calculated when the specific resistance of the electrolyte is known. It is better, however, actually to determine the resistance between the cathode and T during the course of an experiment, more especially when there is a possibility of an increase of resistance at the electrode, owing to the formation of badly conducting deposits, gas-bubbles, etc. The electrical method required for this purpose had to be devised in such a manner that no false connections should be introduced, and that it should at the same time be independent of the polarisation of the electrode. As far as I am aware, the only method suitable for this purpose is one described several years ago by Nernst and Haagn. It consists of a modification of the Wheatstone bridge method for alternating currents, two resistances being replaced by standard condensers, and rough condensers being interposed wherever a false connection would otherwise be made. Its application to the present case is shown diagrammatically in Fig. 3. The two resistances compared are the resistance from the anode to T, and the resistance from T to the cathode, plus a known variable resistance, m. These formed two arms of the Wheatstone bridge, the other two being the standard condensers, a and b (Fig. 3). A special box was made up for this determination containing capacities varying from one-thousandth of a microfarad to half a microfarad. In order to form the bridge containing the telephone between the junction of the two condensers and T, a second auxiliary electrode, P, is required in the liquid contained in the annular space, e (Fig. 1). It was found that an electrode of ordinary smooth platinum answered perfectly well for this purpose. The current for these measurements was derived from a small induction coil, a rough condenser being interposed between it and one of the junctions. The method of working consisted in giving the two standard condensers, a and b, suitable values, say 500 and 20 millemicrofarads, and finding the value, m_1, of the variable resistance, m_1, taken from a dial resistance box that produced a minimum in the telephone. The smaller of the two condensers, b—*i.e.*, the one on the anode side—was then altered to its r-fold value, 20 r millemicrofarads, the other condenser being left unaltered. The new resistance, m_2, was now determined, which produced a minimum in the telephone. The required resistance, x, from the cathode to T is then manifestly derived from the equation

$$\frac{x+m_1}{x+m_2}=\frac{1}{r},$$

its value being

$$x=\frac{m_2-r\,m_1}{r-1}.$$

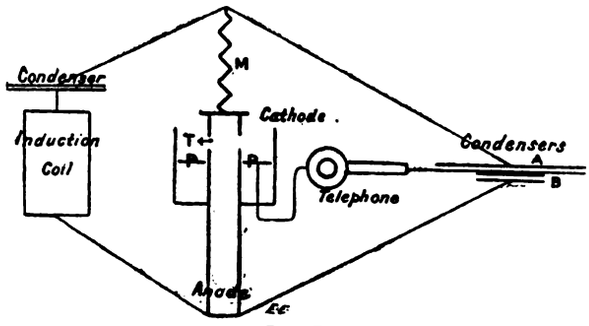

FIG. 3.

The following are details of the apparatus shown in Figs. 1 and 2 that must be specially referred to. The cathode and the glass plate it rests on are both ground perfectly flat. The latter is rectangular in shape, and the edges of the hole, d, drilled in it, are perfectly even and free from chips. The plate is put in position in such a manner that the hole, d, exactly forms the continuation of the tube, C; the way in which it is held on the flanged glass cylinder, h, and the electrode pressed against it by the specially designed clamp, K, will be understood from the Figs. 1 and 2, as also the manner in which electrical connection is made by means of thin copper foil bent round the rubber washer, w (Fig. 2). Practically no leakage took place between the electrode and the glass plate, even when no grease was employed to make a joint. Nevertheless, a small amount of liquid always

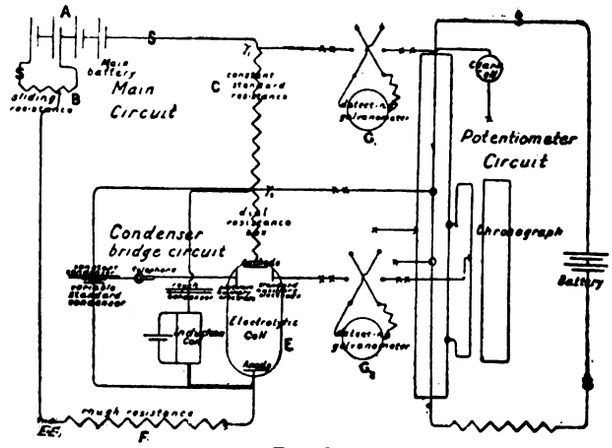

FIG. 4.

creeps up, and this seems to give rise to convection currents owing to evaporation, more especially when alcoholic solutions are employed. A very small amount of vaseline thickened with a little paraffin wax was therefore spread round the edge of the electrode before it was placed in position. In order to guard against its being accidentally moved backwards and forwards over the plate, which would have caused the grease to spread over its surface, a cardboard ring, c, was fixed on the glass plate by means of paraffin wax, and the electrode rotated inside this ring to place it in position. The electrode could easily be levelled both when used as in Fig. 1 and as in Fig. 2, by placing a small spirit-level on the glass plate (Fig. 2), the retort stand, to which the apparatus was attached, being fixed on a levelling stand. The tube, C, the end of which was bevelled, was fixed centrally in the flanged cylinder, H, and was held firmly in position with regard to the latter, not only by the rubber bung, L, but also by means of the two clamps, M and M_2 (Fig. 2), both of which are fastened to a common short rod, n. The clamp M_1 at the same time serves to support the apparatus on its retort stand. The tube, C, ends about ½mm. below the glass plate, thus allowing sufficient room for a liquid connection between the auxiliary electrodes and the liquid through which the working current is passing. The two auxiliary electrodes have already been referred to. The place where the junction between the electrolyte examined and the decinormal solution of KCl of the standard electrode is made, is indicated in both figures by J. The method of filling the tubes, P and O, and keeping the liquid in them by means of cotton-wool plugs before placing the tubes in position will need no further explanation.

Considerable difficulty was at first experienced in

Digitized by Google

arranging the anode to satisfy condition (2). The method finally adopted consisted in the employment of electrodes of either copper or mercury, the electrolyte under examination being displaced in the vicinity of the electrode by a solution of metal salt which was run in slowly through the capillary tap funnel, U (Figs. 1 and 2). The displaced electrolyte was generally removed through the tube, W (Fig. 1). The anode solution, employed in conjunction with the copper electrode, when the electrolyte was an acid alcoholic solution, consisted of cuprous chloride dissolved in a mixture of alcohol and hydrochloric acid. When the electrolyte was an alkaline solution containing alcohol, and also in some experiments on alcoholic acid solutions, a mercury electrode was employed in contact with a solution of mercurous nitrate and a little nitric acid. As the latter, however, as a rule, produced a precipitate in contact with the electrolyte under examination, a solution of ammonium nitrate was interposed. The liquids in this case were run under the electrolyte in the following sequence: (1) ammonium nitrate solution; (2) mercurous nitrate solution; (3) mercury.

The requirement that the apparatus should allow several successive determinations to be performed without taking it to pieces was only met satisfactorily when the cathode was at the top, as in Fig. 1. For this purpose it was necessary to renew the liquid at the cathode by stirring, without at the same time causing anode solution to come into the cathode compartment. As will be seen from Fig. 1, the rubber tube, R, with screw clips, T T, and the glass side tube, S, were, therefore, introduced between the tubes, B and C. The method of using them was the following: When a determination was finished, the side tube, S, which was generally left open during the experiment, was closed, about five cubic centimetres of air being left in it. The standard electrode was then removed by undoing the connection at J, and a rubber stopper with a tap funnel introduced in its place. The screw clips, Y Y, were then closed. A considerable amount of electrolyte was thus forced out of the rubber tube, R, and was allowed to escape through one of the taps. The top part of the apparatus was then taken from the retort stand and moved up and down, the rubber tube, R, being used as a hinge. Air bubbles from the side tube, S, could thus be admitted to stir the liquid and afterwards be returned to the tube S. When it was necessary to leave the apparatus overnight, the anode solution was removed through the tube, u, of the tap funnel, U, being replaced by electrolyte run in through the funnel introduced at J. It was thus found possible to keep the cathode compartment perfectly free from anode solution, even when experiments were spread out over several days. The apparatus was also used for single experiments, without the rather troublesome arrangements allowing a repetition. For the purpose of filling the apparatus as illustrated in Fig. 1, both the funnels U and V must be employed, the top being inverted for filling the upper part through the funnel V. A vent-hole with tap (not shown in the figure) allows the air to escape through the bung, L. The last air bubbles are removed from the cathode through the side tube, S. When in use the apparatus was placed on a non-vibrating shelf.

The electrical arrangements are shown completely in Fig. 4. They comprise the main circuit, the condenser bridge circuit already explained, and the potentiometer circuit. The current was derived from a battery of small accumulators, A, and was kept perfectly constant by variation within suitable limits of the original E.M.F. employed as shown at B (Fig. 4). It passed through a known constant resistance, C, then through a dial box, provided for the purpose of introducing when required the resistance m referred to. As a rule this box was, however, kept free from resistance. After this the current passed through the electrolytic cell, E, and finally through a rough resistance, F, of about the same magnitude as the latter. For the purpose of determining the current strength and the cathode potential, the voltage between the ends, g and g_2, of the known resistance, C, and between g_2 and the standard auxiliary electrode, were measured on the same potentiometer circuit. The latter was composed primarily of a slide-wire with a variable back resistance. As several points of the potentiometer had to be tapped simultaneously during an experiment, a system of wires along which mercury-cups could be moved was arranged in parallel with the slide-wire, and the required potentials tapped off from these mercury-cups, the electrical position of the latter relative to points of the slide-wire being arranged by separate determinations before an experiment. The following manipulation and measurements were carried out during an experiment. The current was kept constant at a known value, the potentiometer regulated by occasional comparison with a Clark cell, and the resistance between the cathode and T measured now and again, as already explained. At the same time, the cathode potential had to be determined by measurement of the E.M.F. between g_2 and the standard auxiliary electrode, and the time had to be read. In order to facilitate the last two determinations a chronograph was designed, which contained a slide-wire that was shunted parallel to part of the potentiometer circuit. The slider on the latter was moved by hand, so as to balance the difference of potential to be measured. Its position, however, was automatically recorded on curve-paper moved past it by means of a drum rotated by clock-work.

With regard to the already explained measurement of the resistance from the cathode to T by means of the condenser bridge circuit, it must be pointed out, firstly, that a false connection is introduced unless the galvanometer, G, for measuring the current is thrown out of circuit during a determination; and, secondly, that the rough resistance, F, is required in the main circuit on account of this measurement in order to prevent the greater part of the current from the induction coil from finding its way through the battery instead of through the electrolytic cell. The resistance taken from the dial resistance box must be so small that its effect on the current during the fraction of a minute it is in circuit need not be considered. All the points of the various circuits that were ever interchanged were connected by special wires to a central switchboard of mercury-cups, on which all the connections were conveniently and rapidly made. All such points are indicated in the figure by x x, other switches being indicated by S.

Results obtained with Aqueous Solutions of Copper Sulphate, Silver Nitrate, and Zinc Sulphate.

The first series of experiments we have to refer to is one carried out with aqueous solutions of metal salts, the substances employed being solutions of copper sulphate, silver nitrate, and zinc sulphate. As long as metal salt is left in the layer of liquid touching the cathode, the metal is deposited from such solutions at a cathode potential, probably either identical with or differing only slightly from the potential at which it is in equilibrium with the solution of its salt. But when the salt has been removed from the electrode by the current, a sudden drop of the potential of the electrode takes place. A marked difference is, however, observed in this connection between solutions of copper sulphate and silver nitrate. In the case of the former the cathode potential drops about one volt, and then becomes fairly constant again. At the same time, the resistance of the layer of liquid around the cathode increases by about 175 ohms per square centimetre, the combined effect being that the difference of potential between the standard electrode and the cathode, as measured in the experiments, increases by 1·2 to 1·3 volts above its original value. The increase of resistance is found to be due to the formation of a deposit of copper hydroxide arising from hydrolysis of the copper sulphate at great dilutions. In the case of the silver nitrate, however, when depletion of the silver occurs, a drop of the potential of the cathode, amounting to only about 0·2 volt, takes place, after which the potential approaches its former value again more or less rapidly. The cathode is then found to have become covered with a mass of silver crystals, which grow into the solution. The curves in Fig. 5 show results obtained with a silver nitrate, and with a copper sulphate solution. As has been shown in the previous communication referred to, the diffusion coefficient of the salts experimented on may be calculated when the time is known which elapses until the concentration of the salt in the layer of liquid at the electrode becomes zero, and this time may be taken as that at which the break in the curve takes place. The actual points chosen on this

Digitized by Google

break were five centivolts in the case of the silver nitrate, and 50 centivolts in the case of the copper sulphate solutions. The formula employed is:

$$k = \frac{1{\cdot}1284^2}{96{,}540^2} \frac{i^2 t n_a^2}{c^2}$$

k being the diffusion coefficient of the salt in $\frac{\text{cm.}^2}{\text{sec.}}$, when c is the concentration of the solution in $\frac{\text{mg.-equiv.}}{\text{cm.}^3}$, i the current strength in $\frac{\text{milamps.}}{\text{cm.}^2}$, t the time in seconds, and n_a the transport value of the anion. Details of the experiments and results are arranged in the following table.

by Nernst from the migration velocities of the $Ag^{\cdot}$ and the NO_3' ion, and which agrees with values extrapolated from Scheffer's determinations of diffusion coefficients. This fact seems to point to the break in the curve occurring before complete depletion of the silver at the electrode has taken place. The matter is, however, undergoing further investigation. See also remarks below regarding deposition potential of copper.

The numbers given in Table II. may be taken as typical results for the determination of the resistance of the copper sulphate solution between the cathode and the junction, T, described. The experiments 1, *a*, *b*, *c*, *d*, were carried out before the current passed through the solution; experiments 2, *a* and *b*, after the break in the potential of the cathode had taken place.

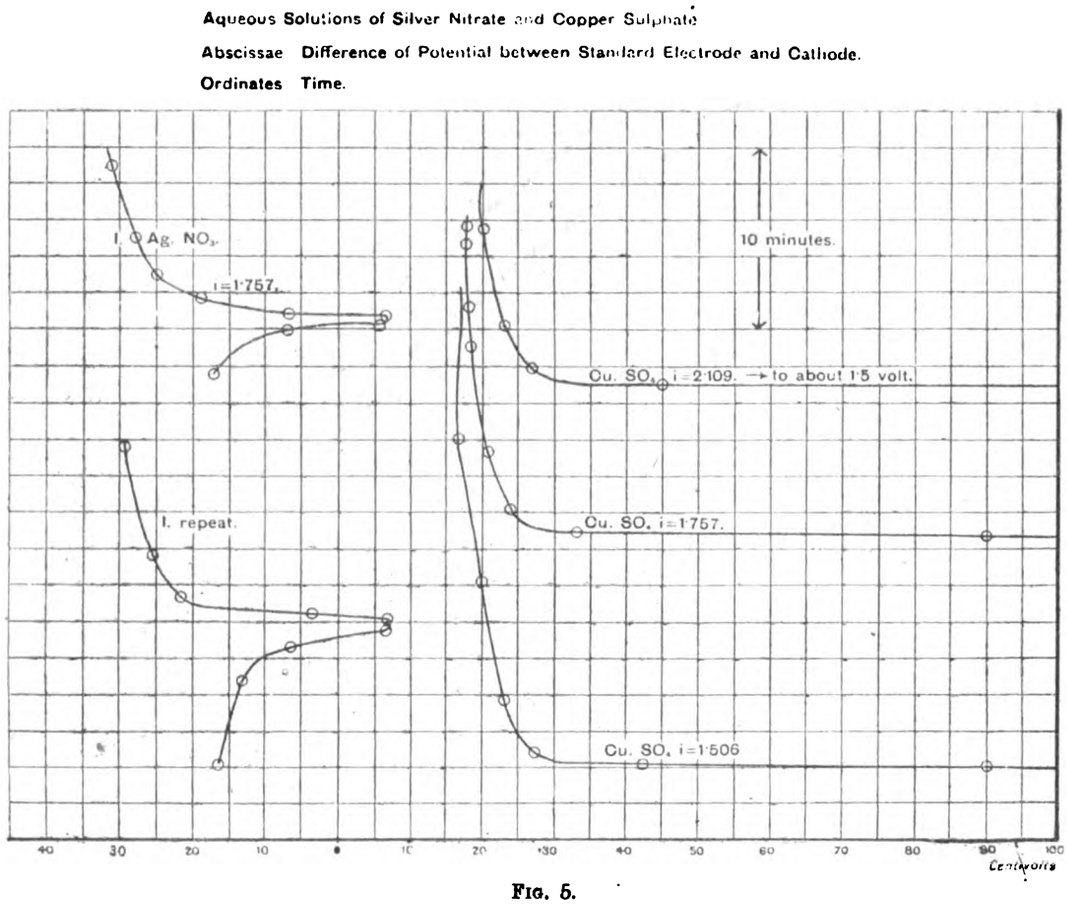

FIG. 5.

TABLE I.

A. Copper sulphate solution concentration 0·204 $\frac{\text{mg.-equiv.}}{\text{cc.}}$ Electrode—platinum-iridium of available surface 0·7589 square centimetre. $n_a = 0{\cdot}63$.

Current density in $\frac{\text{milamps.}}{\text{cm.}^2}$	Time in seconds.	Temperature T in degrees C.	Diffusion coefficient at T degrees in $\frac{\text{cm.}^2}{\text{sec.}}$	Diffusion coefficient at 18deg. by formula $k_{18} = \frac{k\tau}{1+0{\cdot}026\,(T-18)}$
2·109	790	15½	$4{\cdot}58 \times 10^{-6}$	$4{\cdot}86 \times 10^{-6}$
1·757	1,053	16	$4{\cdot}24 \times 10^{-6}$	$4{\cdot}45 \times 10^{-6}$
1·506	1,566	16	$4{\cdot}63 \times 10^{-6}$	$4{\cdot}86 \times 10^{-6}$
1·042	3,297	16¾	$4{\cdot}66 \times 10^{-6}$	$4{\cdot}81 \times 10^{-6}$

B. Silver nitrate solution concentration 0·1 $\frac{\text{mg.-equiv.}}{\text{cc.}}$. Electrode as above. $n_a = 0{\cdot}528$.

1·757	580	18½	$6{\cdot}82 \times 10^{-6}$	$6{\cdot}73 \times 10^{-6}$

According to Wiedeburg, the diffusion coefficient of $CuSO_4$ at 18deg. is $4{\cdot}479 \times 10^{-6}$ for the concentration 0, and $4{\cdot}226 \times 10^{-6}$ for the original concentration of the preceding table. The values in the table thus appear somewhat high. The value found for the diffusion coefficient of silver nitrate is very much too low if we take as correct the number $k_{18} = 12{\cdot}5 \times 10^{-6}$ $\frac{\text{cm.}^2}{\text{sec.}}$, which has been calculated

TABLE II.

No. of experiment.		Ratio of condensers.	Resistance in dial box.	Resistance calculated by the formula.
1	*a*	500 : 20	65	From 1^a and 1^b 77 ohms.
	b	: 40	207	
	c	: 50	278	From 1^a and 1^c 77 ohms.
	d	: 70	425	From 1^a and 1^d 79 ohms.
2	*a*	500 : 50	122	From 2^a and 2^b 218 ohms.
	b	: 100	462	

The potential of the cathode, after allowance had been made for the drop according to Ohm's law between the cathode and the junction, T, was, in the majority of experiments on copper sulphate solutions, found to lie about 10 to 20 millevolts below the potential of equilibrium. This matter, as well as the slight retrogression of potential at the beginning of the experiments which is visible in the copper sulphate curves (Fig. 5), similarly the conditions on which the crystallisation of the silver depends, is undergoing further investigation. Some of the results referred to, if corroborated, would lead to the conclusion that the deposition of metals from solutions like copper sulphate is not an absolutely reversible process, and this again would prove of importance in its bearing on the different nature of metal deposits obtained from different solutions. In a series of experiments on a decinormal zinc sulphate solution with an amalgamated copper electrode similar curves resulted to those obtained with the copper

Digitized by Google

sulphate. Owing, no doubt, to the fact that hydrogen is evolved sometimes after all the zinc has been removed from the solution and sometimes before, according to slight differences in the nature of the electrode, the results were somewhat irregular, and have therefore not been reproduced as curves. The values obtained for the diffusion coefficient of zinc sulphate varied between $3{\cdot}5 \times 10^{-6}$ and $4{\cdot}5 \times 10^{-6} \frac{\text{cm.}^2}{\text{sec.}}$. They point to an increase of the diffusion coefficient of zinc sulphate at great dilutions, the value obtained by Weber for solutions of 2·114 per cent.—*i.e.*, 0·26 $\frac{\text{mg.-equiv.}}{\text{cc.}}$ being $2{\cdot}78 \times 10^{-6}$ $\frac{\text{cm.}^2}{\text{sec.}}$ In agreement with this we should expect the diffusion coefficient of zinc sulphate not to differ greatly from that of copper sulphate at great dilution, owing to the fact that the mobilities of the zinc and the copper ion are nearly equal at great dilution.

(To be continued.)

THE CHANGE OF THE SHIFT.

BY SIMPLEX.

Ho, greaser, say, where is the Shift Engineer?
The volts and the amperes are wandering free.
And bid thou the Driver at once to appear,
For no one regardeth the engines but me.
Yea, tell thou the Stoker his shovel to lift,
For fires must not fail at the change of the shift.

The Shift Engineer in the messroom doth lilt,
And steppeth a sword-dance 'mid poker and tongs.
He weareth his shirt in the place of a kilt,
And tyeth a sponge where the sporran belongs.
The Relief E.-in-C. to hysterics doth drift.
For laughter is free at the change of the shift.

The Driver is playing at thrippenny nap
And counteth his winnings with gurglish glee.
The head of the Stoker is under the tap;
The station is left unto Fortune and me.
Ha! Was it the smell of shellac that I whiffed?
Doth danger impend at the change of the shift?

Ah! Help! For the armature burneth apace!
The greaser in terror hath fled from the scene.
The lights are extinguished; the engine doth race,
And Hades hath come where sweet order hath been!
Vain, vain the excuses sad voices uplift.
There's gnashing of teeth at the change of the shift.

LONDON ELECTRICAL CONTRACTORS' ASSOCIATION.

The annual general meeting of the London Electrical Contractors' Association was held at Frascati's Restaurant on Monday last, Mr. E. L. Berry, the president, in the chair.

The PRESIDENT presented his report, which, among other things, dwelt on the forthcoming London County Council omnibus Bill, and urged all members to use their influence to the utmost to oppose the Bill. He spoke of the model specification and on the advantages of the workmen's certificates, and exhorted all members to continue their interest in the association, directing special attention to the manufacturers' agreement.

The retiring secretary, Mr. E. J. Hogan, was awarded a present of £50.

The following officers were elected: *chairman*—Mr. E. L. Berry; *vice-chairman*—Mr. W. Strode; *treasurer*—Mr. Wm. R. Rawlings; *secretary*—Mr. C. W. Charles; *committee*—Messrs. Phipps, Marryat, Lund, Ratcliffe, Trickett, Joseph, Messop, Troup, Woodward, Tate, Duncan Watson, Blackwood, Wardrop, Owen Smith, Seymour, and Soutar; *hon. solicitors*—Messrs. Turner and Co.; *auditors*—Messrs. Bowden, Smiles, and Co.; *delegates to Central Board*—Messrs. Berry, Lund, Phipps, and Strode.

Mr. R. TWEEDIE SMITH then addressed the meeting at some length, dealing with the apathy of the contractors, and urging all present to use every effort to prevent a system of Tammany in London.

Mr. BERRY then proposed: "That the Central Board be requested to immediately inaugurate strong opposition to the London County Council Bills which are detrimental to the rights of contractors, and that every member throughout the United Kingdom be requested to ensure the opposition of their parliamentary representative."

This was carried unanimously.

GREENOCK ELECTRICITY ACCOUNTS.

The accounts of the Greenock Corporation electricity department for the year ended June 30, 1904, show a total expenditure on capital account to that date of £86,174. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are appended.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	4,781	10	0
Distribution of electricity	290	10	10
Repairs, etc., of public lamps	249	11	11
Rents, rates, and taxes	622	7	3
Management expenses, salaries, etc.	806	6	2
Special charges, insurance, etc.	48	12	9
*Tramways company for current supplied and taken credit for in previous years, but arbiter's award	1,427	3	6
*Arbitration expenses *re* above	753	2	7
	8,979	5	0
Balance carried to net revenue account	3,140	19	11
	£12,120	4	11

* The award given by the Board of Trade arbiter regarding the price of tramway energy applied to all energy supplied since the starting of the tramways in 1901, and as the electricity department had taken credit in the previous two years' accounts for the full price—viz., 1½d. per unit—the whole of the difference between this price and the ·7d. awarded by the arbiter is debited against this year's accounts, in addition to the law expenses. This accounts for the deficit of £2,111. On the year's working there is actually a net profit of £68.

Cr. Income.	£	s.	d.
By sale of current by meter	6,935	13	2
By public lighting	904	10	0
Rental of meters and other apparatus	14	13	9
Sale under contract to tramway company	4,018	16	7
Rents and maintenance of cableways	125	0	0
Installations	105	12	0
Miscellaneous receipts	15	19	5
	£12,120	4	11

GENERAL BALANCE SHEET.

Dr. Liabilities.	£	s.	d.
Balance due to Public Works Loan Commissioners	80,166	13	4
Sinking fund for repayment of loan	9,833	6	8
Accounts due	971	0	0
	£90,971	0	0

Cr. Assets.	£	s.	d.
Capital account—amount expended for works	86,174	16	10
Stores on hand	1,049	14	0
Accounts due for current supplied	1,250	16	3
Due from tramway company for current supplied	381	11	9
Cash balance due by treasurer	2	2	0
Balance at debit of net revenue account	2,111	19	2
	£90,971	0	0

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T.U.			1,585,206
Quantity sold	Public lamps	71,120	1,413,783

APPOINTMENTS VACANT.

Assistant Engineer, Croydon electricity works. Commencing salary, £2 per week. Applications by Nov. 12. See advertisement.

Assistant Electrical Engineer, Oldham Corporation. Salary, £75. Applications by Nov. 14. See advertisement.

Senior Charge Engineer, £130 per annum; General Office Clerk, £78 per annum; Arc-Lamp Trimmers (2), £1. 10*s.* per week each, Acton Urban District Council. Applications by Nov. 10.

Station Superintendent, Chester Corporation. £130 per annum. Applications by Nov. 14.

Electrical Engineer, Battersea Borough Council, £400 per annum. Applications by Nov. 15.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

THE WILLESDEN CASE.

The supply of electricity over any area from a central station is attended with many difficulties, and it is to remove these that the Electric Lighting Acts have been passed. Our readers will remember that the provisions of the earliest Electric Lighting Act, while removing the bulk of the difficulties, imposed others which seriously hampered the electrical industry in the days when every encouragement was needed. The subsequent Electric Lighting Acts, by increasing the period for which powers were granted, again improved matters, but still left the local authorities a veto which has in certain cases retarded the development of electricity supply in smaller districts. Further modifications proposed in this year's Electric Lighting Bill would, if they had become law, have lessened the vetoing power of local authorities, but unfortunately this Bill was one of the massacred innocents. With all this legislation on the subject, we regret to say that even electrical engineers are frequently mistaken in their ideas as to the powers conveyed by electric lighting provisional orders. An example of this is to be seen in the action which was decided last week by Mr. Justice Farwell. In this action the Attorney-General, at the instance of the Willesden Urban District Council, sought and obtained a declaration that the Metropolitan Electric Supply Company had no power to supply energy within the urban district of Willesden. The facts of the case are that the company has works at Willesden from which electricity is transmitted in bulk to its London areas. These works are connected by sidings with the North-Western Railway, and the company at the end of last year commenced giving a supply of electricity to the railway company. This the judge decided was beyond the powers of the company, and an infringement of certain clauses in its Electric Lighting Acts which expressly forbid it to supply electricity outside the areas for which the necessary powers were granted. It was contended by the counsel for the company that the Act of 1898, under which the Willesden generating station was erected, was quite general, and conferred upon the company the power of supplying electricity in Willesden. The case is a most interesting one, and is, we are afraid, liable to be misunderstood by some. It clearly shows the difference between the rights of a private individual and those of a parliamentary company. For example, if the Metropolitan Electric Supply Company had bought the land at Willesden and selected their site in such a way that they could get from it a private wayleave from the station to their older works in London, there would have been no need to apply to Parliament for any powers. If, then, these large works had been erected by a separate company, they would, as we understand the law, have been able to supply electricity to the North-Western Railway Company, and to any other large consumer within the Willesden area whom they could reach by means of private wayleaves—*i.e.*, without crossing the public streets. Instead of this, the company were obliged to seek parliamentary powers, and to submit to parliamentary disabilities at the same time. The case is a most satisfactory one as far as the Willesden Council is concerned, but here again the protection is only against the action of a parliamentary company with powers to supply electrical energy. To illustrate our meaning we would refer to the Hampstead case, in which for years there has been competition between the Hampstead Corporation and the Hampstead Electric Supply Company, which is now known as the North-West London Electric Supply Company. This company has no powers from Parliament, but has succeeded in building up a considerable business amongst consumers which it reaches with private wayleaves only. From the above it will be seen

Digitized by Google

that there is great similarity between an electric lighting provisional order and the ceremony of marriage. Both give special and exclusive rights, and both are subject to strict limitations.

FORTHCOMING EVENTS.

FRIDAY, NOV. 4.

Institution of Electrical Engineers (Manchester Section).—At 7.30 p.m., "Electric Railways," by Mr. F. O. Mills.

MONDAY, NOV. 7.

Society of Engineers.—General meeting.

TUESDAY, NOV. 8.

Crystal Palace Old Students' Society.—At 7.30 p.m., smoking concert at the Caxton Hall.

Royal Colonial Institute.—At 8 p.m., "The Rhodes Scholarship," by Dr. G. R. Parkin.

Institution of Civil Engineers.—At 8 p.m., "Coast Erosion," by Mr. A. E. Carey; and "Erosion on the Holderness Coast of Yorkshire," by Mr. E. R. Matthews.

Institution of Electrical Engineers (Glasgow Section).—At 8 p.m., general meeting.

THURSDAY, NOV. 10.

Institution of Electrical Engineers.—At 8 p.m., inaugural address by the president.

FRIDAY, NOV. 11.

Electro-Harmonic Society.—At 8 p.m., concert (ladies' night).

Tramways and Light Railways Association.—Visit to London County Council's power station at Greenwich, etc.

Physical Society.—At 7.45 p.m., council meeting. At 8 p.m., "Investigation of the Variations of Magnetic Hysteresis with Frequency," by Prof. T. R. Lyle; "The Determination of the Mean Spherical Candle-Power of Incandescent and Arc Lamps," by Mr. G. B. Dyke; exhibition of physical apparatus by Mr. Robert Paul.

SATURDAY, NOV. 12.

Institution of Electrical Engineers (Manchester Students' Section).—Visit to Messrs. Mather and Platt's works.

December—Annual dinner of the Institution of Electrical Engineers at the Hotel Cecil.

REGENERATIVE CONTROL.

A paper was presented on the 20th ult. by Mr. John J. Hall to the Tramways and Light Railways Association on the Raworth system of automatic regenerative control for electric traction. The meeting was held at the Society of Arts, with Mr. T. H. How in the chair. Mr. How, in introducing the subject, humorously remarked that we seemed to be approaching the accomplishment of perpetual motion.

An article dealing with the system will be found in our issue of July 29. After describing the regenerative motor, the shunt field, and line pressure, the paper discusses the question of current consumption. The average cost of current is put at 1½d. per car mile, ranging, however, up to as much as 3d. and 3·34d. in some instances. An average reduction in current consumption of 25 to 30 per cent. is claimed, and on very hilly tracks the economy is put at up to 50 per cent. These figures are based on the assumption that the current is measured on the cars. The author explains that the system does not claim to effect such economy when the consumption is measured on the station wattmeters, owing to the cable and distribution losses, leakage, etc. Reference is made to a trial described in our issue of July 29. In descending a gradient of 1 in 11, the energy returned, as shown by a Vulcan recording wattmeter, was 35·75 per cent. The paper claims that this figure fails to do full justice to the system, the instrument not reading correctly on the reverse or regenerative direction of rotation. The following table shows the result of the investigations made by the Brush Electrical Engineering Company into the operation of the system at Devonport. Records were taken on a recording wattmeter by Elliot Bros. The areas were taken of current consumed and regenerated. The results of their investigation show an over-all efficiency of 31·3 per cent. given in favour of regenerative control.

Route.	Watts consumed.	Ratio returned.	Per cent. returned
Mile House to Fore-street	4·570	·790	17·30
Fore-street to Mile House	4·560	1·955	42·80
Fore-street to Penny-come-Quick	3·095	1·825	58·90
Penny-come-Quick to Fore-street	5·612	·405	7·20
Penny-come-Quick to Camel's Head	11·153	1·780	15·95
Camel's Head to Penny-come-Quick	12·086	5·505	45·70
Average	6·846	2·043	31·30

In considering these particulars it has to be remembered that they are obtained from converted series-parallel motors, where the electrical losses are greater, the paper states, by probably 5 per cent. than would exist in motors specially designed for the regenerative system.

The paper gives the following relative costs of motors and currents: A pair of series-parallel motors of about 30 h.p. costs approximately £150. These operating 100 miles per day on hilly lines absorb on the average 1·5 units per car mile, or 150 units per day. For a year of, say, 300 days the consumption would be 45,000 units, which at an average cost of 1·5d. per unit would cost £281. 5s. At the end of 12 months those motors, with the cost of current added, would therefore amount to £431. 5s. A pair of regenerative motors for similar work would cost, say, £170. For this extra expense the motors can work all day long and do 40 per cent. more work, and at the same time save, say, 25 per cent. of energy required by the series-parallel system. Now 25 per cent. of £281 5s. = £70. 6s. 3d.; and £281. 10s. – £70. 6s. 3d. = £210. 18s. 9d; the regenerative motors costing, say, £170, the current costing, say, £210. 18s. 9d., makes a total of £380. 18s. 9d. Therefore, the series motor and 12 months' current cost £431. 5s.; the regenerative motor and 12 months' current cost £380. 18s. 9d.; showing a saving at end of 12 months of £50. 6s. 3d. as compared with the series-parallel system. The regenerative motors have been taken as costing £20 more than the series motors, "but we see that the makers of this class of motor use the same rated power machine for descending grades when using the electromagnetic brake, therefore there is no need to use a larger machine for regenerative work, so the saving of £50. 7s. 6d. on the first year's work can be increased to £70. 7s. 6d." The braking being effected principally by the motors, the life of the brake gear is greatly extended. Wheel blocks on level track, as a rule, last about six weeks; on hilly routes the life is reduced in some cases to as much as two weeks. In track brakes the shoes in some cases are renewed as often as once a day, and in some very hilly districts as often as twice daily All that involves the use of labour and materials. The life of the wheels is also extended in regenerative control. Where the brake gear is constantly being worn out the labour in the car-shed is correspondingly increased. On braking mechanism and car maintenance generally the author puts the economy roughly as follows: brake blocks and mechanism generally, saving per annum per car = £10; general car-shed labour and attendance = £5; wear and tear of cars, rewheeling, and trueing up = £10—making a total of £25.

In regard to generating plant, the author takes as an example of the saving in first cost a scheme of 100 cars requiring plant of 1,300 kw. capacity. The station, at £40 per kilowatt, would cost £52,000 on the series-parallel system—on the regenerative system the station could be reduced to 910 kw. capacity, securing an economy of £15,000. Further, it is possible to add to the rolling-stock by 30 per cent. without increasing the generating power.

The paper anticipates that in no branch of traction will regenerative control have so far-reaching effects as in railway operation, both for main-line and especially on metropolitan and suburban railways. The same benefits that are apparent in tramway operation will be obtained, but in a more marked degree, for where in this class of work only single cars are dealt with, the higher powers of railways will afford correspondingly greater economies.

The principle of regenerative control having been enlarged upon by Mr. J. S. RAWORTH, a discussion ensued, of which we give a summary.

Mr. H. W. SAYERS, referring to the tests carried out at Devonport, thought that it would be instructive to have more particulars, and remarked that the resistance in the

Digitized by Google

regenerative system appeared somewhat abnormal—of the order of 300 ohms. He thought that the lack of accelerating power, as compared with the S.P. motor, was a serious handicap. In regard to heating of the motors, while conceding that the tests generally applied to the S.P. motor were merely conventional, it appeared quite clear that the shunt motor was not capable of operating at full load as long as its rival. Consequently, it would either do less work or wear out quicker, signifying increased maintenance costs. The promised saving in power to the extent of 25 per cent., representing little more than ¼d., or possibly ½d., per car mile, might soon be absorbed in higher repair and maintenance charges.

Mr. S. SHARP observed that in the Devonport trials the quantity of energy returned showed a wide range, but taking the routes in pairs a pretty uniform mean resulted—30 to 33 per cent.—under similar conditions in regard to grade. Respecting the heating of the motors, he imagined that if Mr. Raworth were having a shunt motor specially constructed, instead of converting an S.P. motor, the windings would be arranged to obviate abnormal heating.

Mr. W. M. MORDEY, after recalling the fact that Sir Wm. Siemens had dealt with this difficult problem over 20 years ago, stated that the figure given in the paper for current consumption was rather overestimated. Taking the average of a number of lines, the consumption worked out at about 1¼ units per car mile. Under certain conditions there was a possibility of saving about 20 per cent. by the use of regenerative control. The system would be much easier of application to alternating currents, but these were not likely to be employed for tramways in the lifetime of the present generation of engineers.

Mr. HUMPHRIES, of the Thanet Light Railway, questioned whether a reduction of current consumption would mean a proportionate saving in the generating plant, as stated by the author. He was not convinced that the slower speed of the shunt motor uphill was compensated by greater speed on the decline, because with the S.P. motor you simply had to work the regulator. Even assuming that a higher speed was obtainable, it was not of much use when the Board of Trade interposed with a limit. Then in regard to the greater safety claimed for the shunt motor in descending hills, he did not think this was demonstrated in the paper.

Mr. HOW, the chairman, then delivered some observations. He thought there was a general disposition to regard the subject favourably, but further demonstration of the advantages claimed would be welcome. Traversing the author's figures for current consumption and charges, he joined with other speakers in considering these somewhat overstated, as also the outlay for S.P. motors. With regard to the economy in current consumption, how was this to be measured? He was not quite sure that we had yet obtained a thoroughly reliable instrument for car service. There were several excellent wattmeters, but he doubted their reliability for tests of high efficiency. Further, the skill and care exercised by the driver was an important factor. Acceleration was not of so much account with tramways, but it would be of the greatest moment with railways. Maintenance promised to be high. Even, however, if the net saving through regenerative control amounted to but half that stated in the paper, he thought it would be admitted that the system was worthy of further consideration.

Mr. RAWORTH admitted that the acceleration achieved under regenerative control was not equal to that of the S.P. motor under all conditions, but in many cases it was quite as good. He emphasised the fact that so far demonstrations had been made only on rewound existing motors. Notwithstanding this, cars driven by regenerative control had always kept schedule time. He gave figures in support of the estimate for power costs. At Southport it cost the Corporation 1·1d. per car mile for energy, while the company, using regenerative control, only stood at an outlay of ·56d.

Mr. HALL, replying, stated that the economy in current consumption was based upon actual tests under service conditions. In regard to sparking, so long as the operating current was kept within 3 per cent. of the armature current the commutation was quite satisfactory. On the question of maintenance, he referred to a letter from Mr. J. Lloyd, manager of the Southport Tramways, which states: "With reference to Demi-car, our experience of the regenerative control is that we have less trouble with it than with any of the S P. cars. The driver himself takes charge of the controller, which takes him about 15 minutes each morning. The shed men examine the under gear each night to screw up any loose bolts; they do not find one a week loose. With the S.P. cars we have one man to clean the controllers each night. We have 13 cars on the road every day, and they take him about 20 minutes to each car. The wheels on the Demi-car have run in service 8,000 miles and 2,000 miles for testing purposes. When the wheels were first put under they were 30in. in diameter, now they are $29\frac{15}{16}$th. The pinions and gear wheels show no signs of wear at all. The commutators show about $\frac{1}{64}$th, and that was made mostly in the extensive trials originally made." Mr. Hall concluded by claiming that when the reduced expense in the general upkeep of the car is added to the decreased current consumption, a substantial economy in favour of regenerative control is shown.

A SCIENTIFIC INVESTIGATION INTO THE POSSIBILITIES OF GAS-TURBINES.*

BY MR. R. M. NEILSON, ASSOCIATE MEMBER.

(Continued from page 636.)

CYCLE I., CASE 4.

It will be interesting to find what efficiency can be obtained with a maximum temperature of 2,000deg. C. by increasing the compression till the ratio of negative work to gross work is 0·4—the same as in Case 1. This ratio will be attained when $t_c = 909$ absolute C., which corresponds to a pressure of 818lb. absolute. Then

$$E = \frac{909 - 290}{909} = 0{\cdot}68.$$

The pressure-volume and entropy-temperature diagrams for this case are given in Figs. 9 and 10. The line B C is shown in dotted lines on Fig. 10 to allow Case 4 to be compared with Case 1. The sharp corner at M would likely be rounded off in practice. This would reduce the efficiency slightly. It would also, however, reduce the maximum temperature, and for this reason it might be advantageous in some cases to round off the corner intentionally.

In every case it has been assumed that the compression is adiabatic; it is usually important that it should be at least nearly so. If, for example, in Figs. 1 and 2, the compression instead of being along the adiabatic A B had been along the line A B_1, which is below the adiabatic line—that is, if heat had been allowed to escape during the compression—the heat absorbed by the fluid for the same value of T would have been increased by the area $b_1 B_1 B a$ in Fig. 2, while the heat converted into work would have been increased only by the relatively small area, A B_1 B. E would, therefore, have been reduced. If, on the other hand, the compression had been along the line A B_2, which is above the adiabatic—that is, if heat had been put into the fluid during compression—the heat absorbed and the heat converted into work would both have been reduced by the same amount—namely, the area A B B_2. E would, therefore, obviously be reduced in this case also, assuming that the heat put into the fluid during compression is obtained by the combustion of fuel. If, however, the heat put into the fluid during compression is obtained for nothing—if, for example, it is heat that would otherwise be radiated away or carried away by convection—the effect on E is not obvious.

A compression along the line A B_2 (Figs. 1 and 2) will give a higher value to E than a compression along the line A B if the heat absorbed during the compression A B_2 is got for nothing, and if the two cases are otherwise the same; but a compression along the line A B_2 produces a higher ratio of negative work to gross work. This will be clear from Fig. 1. Now, with this ratio of negative work to gross work a still higher efficiency could be obtained by

* Paper read before the Institution of Mechanical Engineers.

Digitized by Google

keeping the compression adiabatic and continuing it further. A hot compression, such as along the line $A B_2$ when the heat is got for nothing, may be advantageous in a few cases—viz., when T_1 is low compared with t_c; but generally such a compression will be harmful. It is in general disadvantageous to heat the air or fuel before compression, no matter what be the source of heat.

If gas is allowed to enter a water-cooled turbine at a high temperature, such as 2,000deg. C., there will necessarily be a great amount of heat carried away by the water. In a reciprocating engine the metal surface with which the gas comes into contact is very small compared with that in a multiple-expansion turbine, and in a reciprocating engine the bulk of the gas may expand and fall from its maximum temperature to the temperature at exhaust without ever coming near a metal surface. In a multiple-expansion turbine, on the other hand, every particle of gas must practically slide along a metal surface immediately it comes to the first ring of blades. With turbines employing gas which enters the turbine casing at such a temperature, the heat lost through the walls and

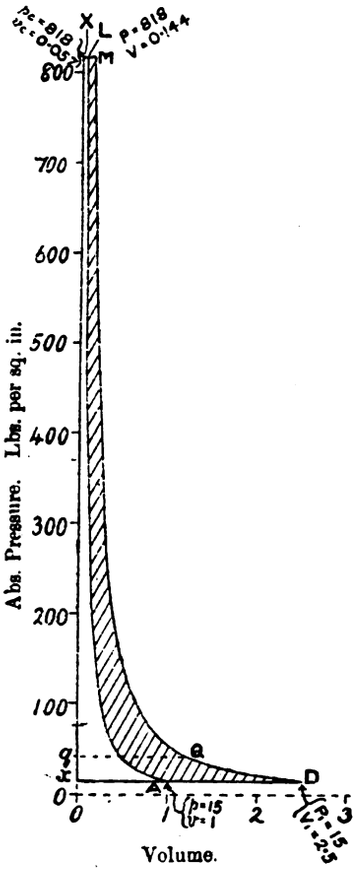

FIG. 9.—Cycle I., Case 4. Pressure-Volume Diagram.

carried away by the water must necessarily be very great indeed. It is true that the metal surface in contact with the gas can be allowed to be at a much higher temperature than the inside of the cylinder walls of a reciprocating engine; but, in spite of this, the heat lost through the walls and carried away by the cooling water (or other cooling medium) will probably be much greater with a turbine actuated by gas entering the turbine casing at about 2,000deg. C. than in a reciprocating engine in which the maximum temperature is 2,000deg. C. This loss of heat will cause the actual work done by the engine to be very much below the ideal. This is not only important in itself, but, as will be explained later on, it prevents us usefully employing a high ratio of negative work to gross work. The question of utilising this lost heat will be discussed later on.

CYCLE I., CASE 3A.

Instead of employing cooling arrangements for the metal, some or all of the available heat energy of the gas can be converted into kinetic energy before causing it to act on the turbine, so that the latter is not exposed to an unduly high temperature. This can be done by allowing the gas when at the maximum temperature to expand in a divergent nozzle till its temperature falls to a degree that the turbine can stand. More than one nozzle can be employed, but to reduce the radiation losses the nozzles should be large and few in number. Suppose that the gas is compressed adiabatically to 300lb. absolute, and then is heated at constant pressure to a temperature of 2,273deg. absolute C., as in Case 3. If now the gas be allowed to expand in a suitable nozzle, adiabatic expansion can be obtained, and if this be continued till the pressure falls to 15lb. absolute, the temperature will be 966 absolute C. (693deg. C.). This is just below the temperature which was fixed on as a maximum for a turbine without artificial cooling. The entropy-temperature diagram will be the same as in Case 3 (Fig. 8), and E will therefore be the same—namely, 0 58 The ratio of negative work to gross work will also be the same as in Case 3—namely, 0·3.

Referring to the pressure-volume diagram for Cycle I., Case 3 (Fig. 7), the area z Z H K represents the kinetic energy of the gas leaving the nozzle, which kinetic energy equals 33,840 foot-pounds. This is for a quantity of gas that measures one cubic foot at A. The velocity is 5,290ft. per second. It may be advantageous to mention for the sake of comparison the velocities of the steam jets employed in De Laval steam-turbines. If saturated steam at 50lb. absolute pressure is expanded adiabatically to a pressure of 0·6lb. absolute, which corresponds to a temperature of 85deg. F., and its heat energy turned into

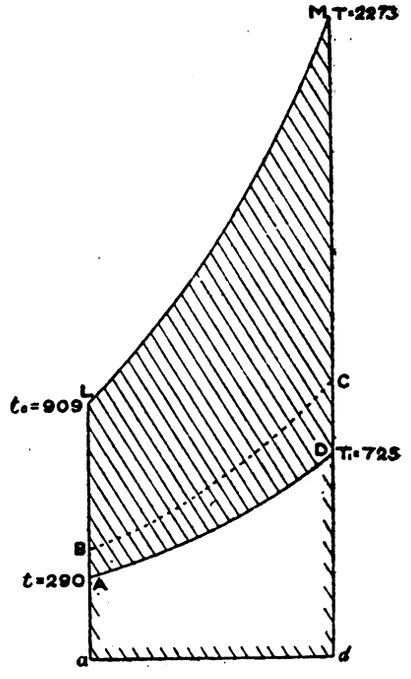

FIG. 10.—Cycle I, Case 4. Entropy-Temperature Diagram.

kinetic energy, the velocity acquired works out at 3,690ft. per second. If saturated steam at 300lb. absolute pressure were treated similarly, the velocity would be 4,380ft. per second. The velocities actually obtained in practice must be somewhat less than these figures, owing to friction in the nozzles.

To get the best results from a fluid velocity such as 5 290ft. per second would require, with a single turbine wheel, a vane speed which cannot be obtained at present for want of a sufficiently strong and light material—the stresses produced by centrifugal force are too great. This difficulty is experienced with De Laval turbines. The obvious way out of the difficulty is to employ several wheels in series, the gas passing through the several wheels with diminishing velocity, but with nearly constant pressure. This has been done in steam-turbines. With the same object of reducing the vane speed, a device has been proposed whereby the nozzles are mounted on a wheel which rotates in the opposite direction to the wheel carrying the vanes. If the two wheels rotate at the same speed (in opposite directions) this speed will be half of that of the single wheel if the nozzles were stationary. The centrifugal force is therefore only one-fourth of what

Digitized by Google

it would otherwise be. The frictional losses in the nozzles of a gas-turbine will probably be less than those in a steam-turbine for the same velocity of exit from the nozzle.

Cycle I., Case 4A.

Let us now try working to the same entropy-temperature diagram as in Case 4 (Fig. 10), but employing a divergent nozzle, as in Case 3A, to reduce the maximum temperature to 700deg. C, so that the gas can be used in a turbine without cooling arrangements. T_1 in this case will be 723deg. absolute C. (452deg. C.). It is not necessary, therefore, to perform all the adiabatic expansion in a divergent nozzle, but a portion of it can be performed in the turbine. If the fluid is expanded in the nozzle only till its temperature falls to 700deg. C., the pressure will then be 42lb. absolute; so that 27lb. can be dropped in the turbine

Referring to the pressure-volume diagram for Cycle I., Case 4 (Fig. 9) the line q Q is drawn to represent the pressure at which the gas leaves the nozzle. The kinetic energy of the gas leaving the nozzle is represented by the area X M Q q. This we can find amounts to 33,660 foot-pounds (for one cubic foot of gas measured at A), and the velocity works out at 5,280ft. per second. E will be the same as in Case 4, and so will the ratio of negative work to gross work. It seems to the author that an engine working on this cycle, according to Case 3A or Case 4A or between these, has good prospects. The ideal efficiency is high, from 0·58 to 0·68. How near one could approach this efficiency in practice would depend, of course, both on the losses in the motor proper and on the losses in the pump.

The losses in the motor proper may be taken to include the losses in the combustion chamber if such is employed and in the nozzles. The motor losses will then consist of (1) loss of heat by radiation and conduction; (2) fluid friction; (3) friction in turbine bearings; (4) loss due to incomplete expansion. The first loss will be large, but should be less than in reciprocating engines, owing to the higher velocities employed and to the higher temperatures allowable in the metal. The second loss will be considerable, but much less than in turbines using saturated steam. It has been found by experiment that hot dry air causes much less friction than wet steam. (The steam is always wet in a De Laval turbine casing, unless it enters the nozzles with a large amount of superheat.) The third loss will be trifling, and the fourth loss should be moderate. The discharge of heat with the exhaust gases is here only considered as a loss in so far as it exceeds that of an ideal engine.

It is difficult to estimate the pump losses. Rotary compressors on the turbine principle seem to have been employed only up to about 80lb. pressure. Whether or not they are suitable for high pressures is a point which we want very badly to know about. One would be inclined to believe that the fluid frictional losses with such machines would be very great if attempts were made to obtain high pressures. It by no means follows, however, that a fairly efficient rotary air-compressor cannot be devised. A reciprocating compressor always has the disadvantage that the air when drawn in becomes heated by contact with the hot metal surfaces before compression commences. This evil is reduced by compounding. It is an evil that occurs to a serious extent with reciprocating gas-engines working on the Otto cycle With a reciprocating compressor it will be difficult to avoid the necessity of jacketing the cylinder if high compressions are employed. This will bring the compression curve below the adiabatic and reduce the efficiency, as before explained. In any case, whatever be the nature of the pump, there is bound to be a certain amount of heat passed through the walls of the pump cylinders or casing. If this loss is made up by friction or impact within the pump, the compression may be along an adiabatic curve, but the loss will still have to be paid for.

The ratio of negative work to gross work is somewhat high—0·3 to 0·4. In the case of a turbine one need not fear the increase in the bulk of the engine due to this high ratio, for the bulk of the turbine will probably be very small for the power. Frictional and other losses become, however, of much greater importance when the ratio is high. To show this forcibly, consider an extreme case. Suppose that the ratio of negative work to gross work in an ideal engine is 0·5, or, in simpler language, suppose that the pump requires half the gross power of the machine, there being no friction. If, now, the machine is not ideal, and if the mechanical efficiency of the pump is only two-thirds, and that of the motor proper only three-quarters, no useful work whatever will be got out of the machine—all the work will be absorbed by friction. For if the power of the motor proper, including that spent on friction, is 100, the pump will require 50, and as its efficiency is two-thirds, it will take 75. This is exactly what the motor will give out after deducting friction. There will therefore be no power got out of the machine.

When there is a high ratio of negative work to gross work, success will therefore be dependent largely on the efficiency of the pump. Unless the pump is at least fairly efficient, success cannot be expected. In the Diesel engine the bulk of the air is compressed to about 500lb. per square inch, and the air which carries the oil into the cylinder is compressed from 100lb. to 200lb higher.* It would be interesting to know with what efficiency the air is compressed in the Diesel engine.

Otto cycle reciprocating engines having ideal efficiencies of 0·4 to 0·45 have given practical efficiencies of half that amount. By practical efficiency is meant ratio of brake horse-power to thermal units in gas consumed, calculated on the higher calorific value. When the ideal efficiency is increased above 0·45 the ratio of practical efficiency to ideal efficiency usually falls below 0·5—the greater the ideal efficiency the greater are the losses. With a turbine the losses ought also to increase when the ideal efficiency is increased, but whether to the same extent as with an Otto engine it is difficult to say. When considering high compressions it is well to note that the Diesel engine with a high compression and an incomplete expansion has given some of the highest practical efficiencies yet attained. The compression should not cause the same trouble in starting a turbine as in starting a reciprocating engine, as with a turbine we should be able to arrange that at every instant the gross work is greater than the negative work. With a reciprocating engine having a single cylinder working on the Otto cycle we have, of course, periods when the negative work exceeds the gross work.

Cycle II., Case 1.

With regard to explosion turbine engines, suppose that the fluid is compressed adiabatically to, say, 101lb. per square inch absolute—that is, to a temperature of 500deg. absolute C. Let it now be heated at constant volume by explosion, and let there be a mixture of such a strength that the temperature will rise to 2,000deg. C. (2,273deg. absolute C.). The pressure will then be 459lb. absolute. If the gas is now allowed to expand adiabatically till its pressure is atmospheric (when its temperature will be 855deg. absolute C.), and then cooled at that pressure till it resumes its original state, the pressure-volume and entropy-temperature diagrams will be as shown in Figs. 11 and 12. In Fig 12 the heat supplied to the fluid is represented by the area a R T s, the heat rejected by the area a A S s, and the heat converted into work by the area A R T S.

$$E \times \frac{\text{area A R T S}}{\text{area } a \text{ R T } s} = 0{\cdot}55.$$

The negative work can be compared with the gross work in Fig. 11. The ratio of negative work to gross work $= \frac{\text{area } v \text{ V R A}}{\text{area } v \text{ V R T S}} = 0{\cdot}23$. Cycle II., Case 1, very nearly resembles common practice to-day with reciprocating explosion engines. The expansion is, however, continued to atmospheric pressure. This, as a rule, is not desirable in a reciprocating engine on account of the extra length required to be given to the engine cylinder. This not only increases the loss by friction, but increases the loss of heat by the expanding gas, and if the same length of stroke is employed for drawing in the fresh charge, increases the heating of the charge before compression. The case, however, is very different with turbines, and there seems

* "The Diesel Engine," by H. Ade Clark. Paper read before the Institution of Mechanical Engineers at Leeds in July, 1903, p. 395.

Digitized by Google

no good reason why with these the adiabatic expansion should not be carried practically to atmospheric pressure. In practice the maximum pressure and the average maximum temperature throughout the gas would be less than the values here indicated owing to radiation losses.

Cycle II., Case 1A.

The gas could not be allowed into an uncooled turbine at the maximum temperature in Cycle II., Case 1; but if the expansion were performed wholly or nearly wholly in a divergent nozzle, the temperature of exit from the nozzle

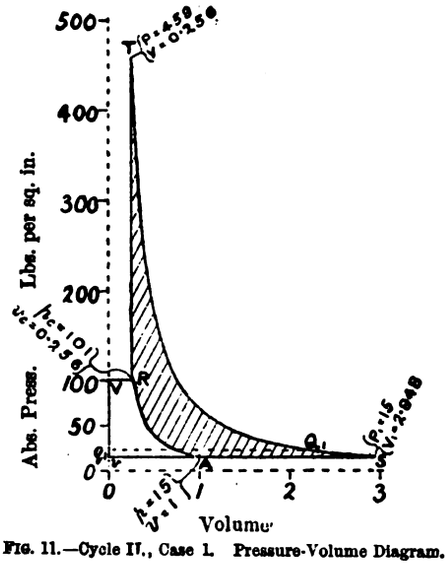

Fig. 11.—Cycle II., Case 1. Pressure-Volume Diagram.

would be sufficiently low to allow of the gas entering an uncooled turbine. For example, if the gas at the maximum temperature of 2,273deg. absolute C. and the maximum pressure of 459lb. absolute were expanded in a perfect divergent nozzle till the temperature fell to 700deg. C. (973deg. absolute C.), which was fixed on as the maximum allowable temperature in an uncooled turbine, the mean pressure on leaving the nozzle would be 23·5lb absolute.

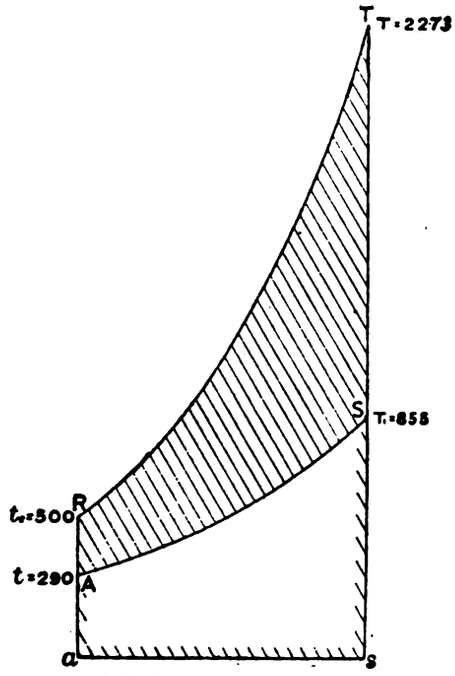

Fig. 12.—Cycle II., Case 1. Entropy-Temperature Diagram.

The kinetic energy of the gas (one cubic foot at A) on leaving the nozzle would be represented by the area V R T Q_1 q_1 in Fig. 11, and would amount to 20,500 foot-pounds. The mean velocity (the square root of the mean square) would be 4,120ft. per second. On comparing Cases 1 and 1A of Cycle II by reference to the table with Cases 2, 3, 3A, 4, and 4A of Cycle I., which have the same maximum temperature, it is found that the efficiency is very much greater than Cycle I., Case 2, is nearly as great as Cycle I., Cases 3 and 3A, and is considerably below Cycle I., Cases 4 and 4A. The ratio of negative work to gross work is, however, greater than in Cycle I., Case 2, and less than in Cases 3, 3A, 4, and 4A of Cycle I.

There are two objections to the user of turbines of a cycle such as Cycle II., and these objections must be set against the advantage which turbines would possess over reciprocating explosion motors in being able to make better use of the tail end of the pressure volume diagram. One of the objections is that explosions at constant volume have to take place intermittently, while a turbine desires a continuous supply of fluid. If the supply is not continuous, the power of the turbine is less than it would otherwise be for a given size of machine, and the initial cost, the bulk, and—most important—the loss by friction are greater in proportion to the power developed than they would otherwise be. The other objection is that the fluid must leave the explosion chamber at varying pressure. This necessitates, unless special means are provided to prevent it, the fluid entering the turbine casing either at varying pressure or at varying velocity. This, of course, is objectionable, as the speed of rotation of the turbine cannot during the period of a cycle be made to vary correspondingly.

The second objection might be met by employing in a parallel-flow turbine of the De Laval type long radial blades, and causing the nozzles to be altered in position according to the pressure, so as to direct the gas on to the outer ends of the blades at high pressures and on to the inner ends of the blades at low pressures. The difficulty could also be met by an arrangement of reciprocating engine combined with a turbine, the gas being first expanded in the reciprocating engine to a certain pressure and then passed on to the turbine to complete its expansion. If several reciprocating cylinders were employed, the first objection also would be got over. It is true that with such a combination some of the most important advantages of the turbine would be lost. The idea is, however, in the author's opinion, worthy of consideration. Reciprocating steam-engines have been successfully combined with steam-turbines in this manner.*

Cycle II., Case 2.

An explosion engine in which a very high compression pressure is employed will now be considered. If compression be carried to 818lb. absolute as in Cycle I., Case 4, one obtains with a maximum temperature of 2,000deg. C. a maximum pressure of 2,045lb. absolute, and a very high ratio of negative work to gross work. If a much lower compression—namely, 417lb. absolute—is adopted, this will give a temperature of compression of 750deg. absolute C. Working on the same cycle as in the last case, and arranging the explosive mixture to give a maximum temperature of 2,000deg. C. (2,273deg. absolute C.), a maximum pressure of 1,265lb. absolute is obtained, and the pressure-volume and entropy-temperature diagrams will be as shown in Figs. 13 and 14. Referring to Fig. 14,

$$E = \frac{\text{area A U W W}_1}{\text{area } a\,\text{U W } w} = 0{\cdot}68.$$

Referring to Fig. 13,

$$\frac{\text{neg. work}}{\text{gross work}} = \frac{\text{area } u_1\,U_1\,U\,A}{\text{area } u_1\,U_1\,U\,W\,W_1} = 0\,38.$$

E is the same as in Cycle I., Case 4, and the ratio of negative work to gross work is also the same. The compression is lower than in Cycle I., Case 4, but the maximum pressure is very much higher. The excessively high maximum pressure is an objection to this case.

Cycle II., Case 2A.

If the expansion took place in an ideal divergent nozzle, as before, till the temperature fell to 700deg. C. (973deg. absolute C.), the gas would still have a pressure of 70lb. absolute, while the mean velocity of exit from the nozzle would be 4,300ft. per second. If the gas were expanded in the nozzle down to 25lb. absolute, the temperature would then be 741 absolute C., and the mean velocity of the gas leaving the nozzle would be 4,830ft. per second.

* See paper by Prof. Ratean read before the North of England Institute of Mining and Mechanical Engineers at Newcastle-on-Tyne, Dec. 13, 1902; or paper by the same author read at the Chicago meeting of the Inst. of Mech. Engineers, 1904.

Cycle III., Case 1.

It has been proposed, when a water jacket is employed, to utilise the heat passed into the jacket water by causing this heat to generate steam from this water. This steam could then receive further heat from the products of combustion, which would therefore be reduced in temperature, while the steam would be superheated. The steam and products of combustion could then expand adiabatically, doing work in the same or in separate turbines. The carrying out of this idea would affect the efficiency in the several cases considered of Cycle I. Cooling arrangements are not required in Cycle I., Case 1, so this case need not be further considered. In Cycle I., Case 2, let it be supposed that the combustion chamber is jacketed, and that the

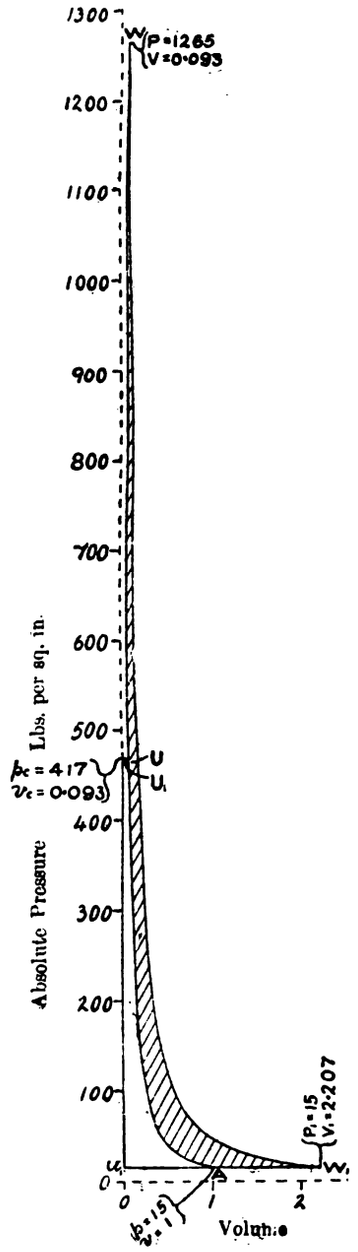

Fig. 13.—Cycle II., Case 2. Pressure-Volume Diagram.

jacket water is heated and converted into steam by heat taken from the products of combustion, which have their temperature thus lowered from 2,000deg. C. to 700deg. C.—that is, to the temperature at which they can safely be allowed into an uncooled turbine, the steam being superheated up to 700deg. C. Let this be called Cycle III., Case 1.

Referring to Fig. 6, the heat in the products of combustion which is converted into work is now represented by the area A B C D instead of by the area A B E F. The heat represented by the area *d* C E *f* has, however, been employed in heating water and generating and superheating steam. The fraction of this heat which is converted into work will not now be as great as in the original scheme of working. That is to say, the net work got out of the heat put into the water and steam will be less than the area D C E F. By transferring heat to the water and steam from the gas, E is, therefore, reduced. There must, however, in any case, as already mentioned, be lost in practice a large amount of heat from the products of combustion when these products of combustion enter the turbine casing at a temperature such as 2,000deg. C., and, by adopting this combined steam and gas scheme, a much

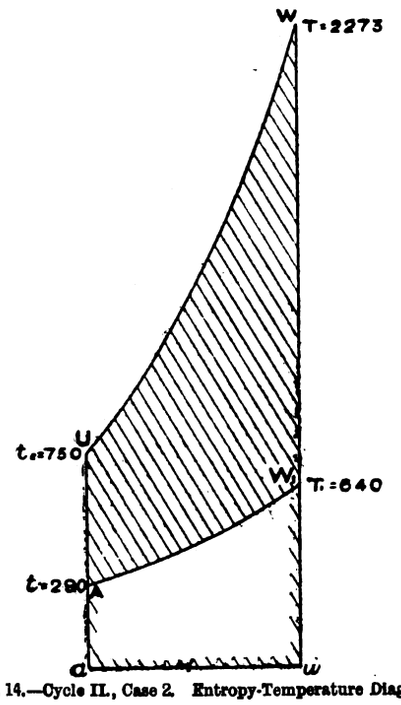

Fig. 14.—Cycle II., Case 2. Entropy-Temperature Diagram.

higher practical efficiency may possibly be obtained than would otherwise be possible. As the net work ideally is less than in Cycle I., Case 2, and as the negative work is not less (and may be greater by the amount of work required to pump the water into the jacket if under pressure), the ratio of negative work to gross work is increased. In Case 2 of Cycle I., the ratio of negative work to gross work is low, and it will be, therefore, allowable to increase this ratio.

Cycle III., Case 2.

Case 3 of Cycle I. could be modified in the same way by reducing the temperature of the products of combustion from 2,000deg. C. to 700deg. C., and by employing the heat so given up in heating water and generating and superheating steam. The steam could be generated at 300lb. pressure absolute (the same pressure as the products of combustion) and superheated to 700deg. C. at this

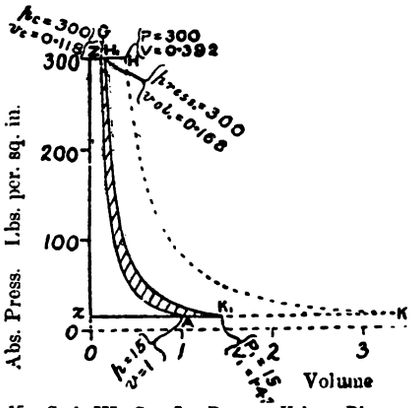

Fig. 15.—Cycle III., Case 2. Pressure-Volume Diagram—Gas.

pressure. The steam and gas could then be expanded adiabatically in the same or in separate turbines. As in the previous case, E would be reduced, and the ratio of negative work to gross work increased. As in the previous case also, the practical efficiency might be largely increased.

The pressure-volume and entropy-temperature diagrams for the gas in this case (called Cycle III., Case 2) are shown in Figs. 15 and 16 respectively. The gas is compressed along the line A G as in Cycle I., Case 3,

Digitized by Google

till its pressure is 300lb. absolute, and its temperature is 409·5deg. C. (682 5deg. absolute C.). It is then heated by combustion at constant pressure along the line G H as in Cycle I., Case 3, till its temperature is 2,000deg. C. (2,273deg. absolute C.). Heat is now withdrawn from the

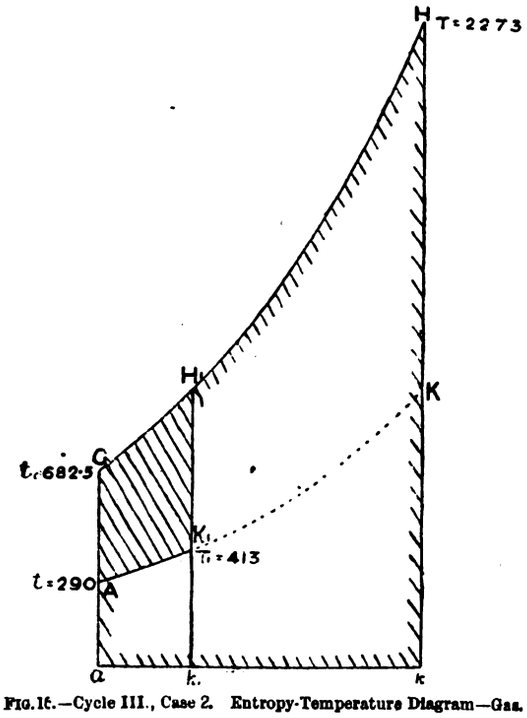

FIG. 16.—Cycle III., Case 2. Entropy-Temperature Diagram—Gas.

gas at constant pressure and transferred to the water and steam, the temperature of the gas falling along the line H H_1 to 700deg. C. (973deg. absolute C.) at H_1. The heat transferred from the gas to the water is represented (Fig. 16) by the area k_1 H_1 H k. The gas now expands adiabatically along the line H_1 K_1 till the pressure is 15lb. absolute, when the temperature will be 140deg. C. (413deg. absolute C.). The contraction of the gas at constant pressure along the line K_1 A completes the cycle. Dotted lines have been placed on Figs. 15 and 16 to illustrate Cycle I., Case 3, where this differs from the present cycle. The two cycles can thus be compared.

Pressure-volume and entropy-temperature diagrams for the water are shown in Figs. 17 and 18. Referring to Fig. 18, the water is heated at a constant pressure of 300lb. per square inch absolute along the line f c from 100·6deg. C. (373·6deg. absolute C.) to 214deg. C. (487deg. absolute C.), which is the boiling point at this pressure. The water is now converted into steam, this process being represented by the line c g; and the steam is superheated at constant pressure as represented by the line g d till its temperature is 700deg. C. (973deg. absolute C.). The steam is then expanded adiabatically along the line d e till it falls to 15lb. pressure absolute, its temperature then being 184deg. C. (457deg. absolute C.). The steam is now exhausted and cools along the line e h. At h it is saturated, its temperature being 100·6deg. C. (373·6deg. absolute C.), and thereafter it condenses along the line h f, and is compressed to its initial state. Fig. 17 shows the work done by the steam in its generation, superheating, and adiabatic expansion. The work done in forcing the water into the chamber at 300lb. pressure is not shown in Fig. 17, and is negligible in an investigation of the nature of the present.

The heat required to raise the water from 373·6deg. absolute C. to 487deg. absolute C. is represented in Fig. 18 by the area f_1 f c c_1. The area c_1 c g g represents the latent heat of steam at a pressure of 300lb. absolute (the temperature being 487deg. absolute C.), and the area g_1 g d e_1 represents the heat required to superheat the steam from 487deg. absolute C to 973deg. absolute C. The area f_1 f h h_1 represents the latent heat of steam at a pressure of 15lb. absolute, and the area h_1 h e e_1 represents the heat required to superheat this steam from 373·6deg. absolute C. to 457deg. absolute C.

Comparing this case with Case 3 of Cycle I., it is found that the total heat absorbed is the same in both cases, being represented by the area a G H k in Fig. 16. The portion of this heat which is converted into work in Case 3,

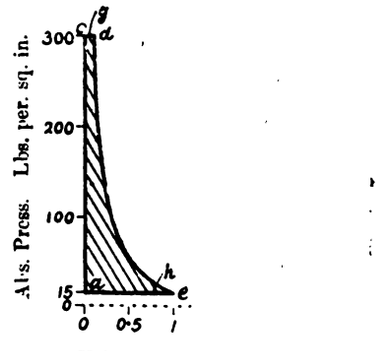

FIG. 17. - Cycle III., Case 2. Pressure-Volume Diagram—Steam.

Cycle I., is represented by the area A G H K, while the corresponding portion in the present case is represented by the sum of the areas A G H_1 K_1 (Fig. 16) and f c g d e h (Fig. 18). This sum is less than the area A G H K, and E in this case is only 0·33 as compared with 0·58 for Case 3 of Cycle I. The fall in the value of E is due to the relatively low efficiency of the steam portion, which has an ideal efficiency of only 0·28. (This is really not low for a steam-engine.)

The feed water has been taken at a temperature corresponding to atmospheric boiling point. It has been assumed that the steam is exhausted into the atmosphere, and is not condensed for use over again. It would, therefore, be necessary, in order to follow the cycle, to heat the feed water to 100deg. C. It should not be difficult to approximately accomplish this by utilising the heat of the exhausting gases. By heating the feed water still more

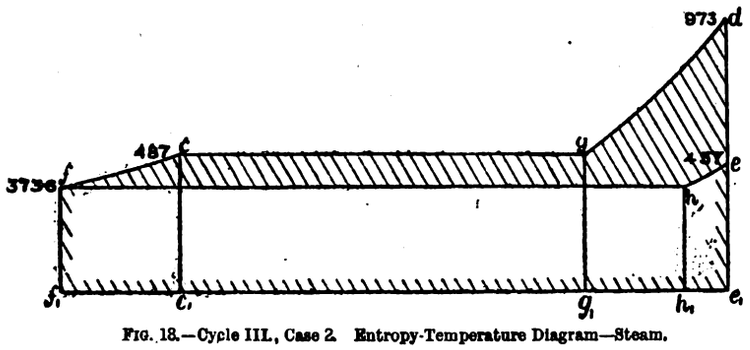

FIG. 18.—Cycle III., Case 2. Entropy-Temperature Diagram—Steam.

the efficiency could be improved; but the improvement would be slight (less than in an ordinary steam-engine), and the feed water would have to be under pressure. As, moreover, any increase of exhaust or back pressure is a serious matter with a turbine, and as feed-water heaters must to a certain extent affect this back pressure, any prospect of gain by heating the feed water beyond 100deg. C. need not be considered.

The gross work in the present case is represented (Figs. 15 and 17) by the area z Z H_1 K_1 + the area a c d e. This is less than the gross work in Cycle I., Case 3, which is represented by the area z Z H K. The negative work in Cycle I., Case 3, was represented by the area z Z G A. In the present case it is also represented by this area, neglecting the work of pumping the water into the jacket.

Digitized by Google

The ratio of negative work to gross work in the present case is 0 41, as compared with 0·3 in Cycle I., Case 3. This ratio (0 41) is rather high. It will, however, probably not be so objectionable in the present case as the ratio 0 40 in Case 4 of Cycle III., as the real efficiency in practice will come nearer to the ideal in this case than in Case 4 of Cycle III. We could in the present case reduce the ratio by lowering the compression. This would reduce E.

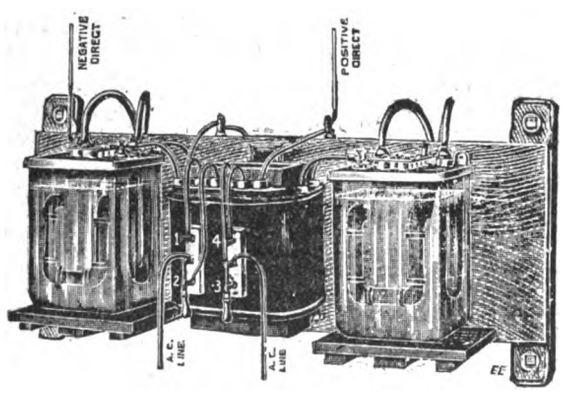
As the mass of the water employed is not the same as the mass of the air and fuel, the scale for entropy in Fig. 18 has been made different from that in the other entropy-temperature diagrams, so that in all these diagrams areas represent quantities of heat to the same scale. In all the pressure-volume diagrams the scales are the same, except in Fig. 19, which will be referred to hereafter. It might be mentioned here that all the numerical results given in this paper have been obtained by calculation and not by scaling the diagrams.

(To be continued.)

THE CHURCHER ALTERNATING RECTIFIER.

We take from our American contemporary, the *Journal of Electricity, Power, and Gas*, the following interesting description of the Churcher alternating-current rectifier, which is a decided departure :

Much hard work must be done, difficulties overcome, methods of manufacture and sale perfected, before any real success is achieved. Such has been the case with the alternating-current rectifier, about which more or less has been written in the last few years. It is not a newly discovered fact that aluminium and some other metals have the faculty of developing upon their surfaces an insulating film when in contact with certain solutions, and while electrically positive to another electrode in the same solution, but it has remained in an unperfected state.



The Churcher Alternating Rectifier.

The Churcher alternating-current rectifier is a decided departure from anything before constructed, and is now in marketable and practical shape. The best that has been accomplished heretofore was a very inefficient and crude device. A single cell with a pair of suitable elements will rectify part of the cycle of an alternating current, but this is not a true unidirectional current. It is still an alternating current in character with one alternation of greater amplitude than the other, and giving an efficiency of perhaps 20 per cent. when charging a storage battery. This poor result is partially caused by the return or leakage current passing through the rectifier and through the battery in the wrong direction, hence discharging it. To charge a storage battery under this condition, it is evident that an excessive charging current must be used to overbalance the excessive discharge that takes place during one-half of the cycle. For example, in figures that are approximately correct, to charge a battery of cells aggregating 50 volts a potential of about 60 volts is ordinarily required. Supposing, for illustration, that this potential will pass 10 amperes through the cells on direct-current circuit. In order to charge at this rate from an alternating current with a single old-type rectifier, it will be necessary to raise the charging potential sufficiently, say to 75 volts, to force 50 amperes through the cells—an excessive charge. This is because of the fact that the potential of the return wave of the alternation will be added to that of the battery, and produce a serious leak through the insulating film on the aluminium electrode. The average discharge potential would be 50 plus 75, or 125 volts. Average, because at the peak of the alternation the actual potential would reach about 150 volts against the film, which is approximately its breakdown point. This high return potential, as it may be termed, will cause a discharge of about 40 amperes—an excessive discharge rate. This leaves a net charging current of 10 amperes It is presupposed that a battery requiring 10 amperes would have capacity of about 100 ampere-hours, and hence it will be seen that in order to charge at 10 amperes from the old type of rectifier it was necessary to charge at 50 and discharge at 40 amperes, leaving the required margin for charging. At this rate the rectifier would be rapidly destroyed, and the best storage battery would be served likewise. A rectifier of that type is not worthy of further consideration, as it is of no more real value for other purposes than for charging batteries.

The next step was the combination of four rectifying cells, known as the Graetz method of connection. This combination was somewhat better, in that it rectified both waves of the cycle, and hence gave a true unidirectional current. The efficiency was necessarily low, because of the fact that the resistance in the path of the useful current was double, and leakage was also double that of a single rectifier. The old type of single cell being inefficient to start with, the combination of four was nearly four times as bad, to say nothing of the wear and tear on four sets of electrodes and four solutions. The only gain was a really unidirectional current produced, so that in charging a storage battery all of the energy passing through it was available for discharge, barring, of course, inherent losses peculiar to storage batteries.

The next step was the perfection of the Churcher rectifier. This device rectifies both waves of any alternating current and requires but one jar, one solution, and one set of electrodes to do so. In this way the internal resistance is reduced to a very low point—in fact, it is only limited by mechanical necessities to prevent short-circuits. This loss is almost negligible. The principal loss that does take place is the leakage current. This current does not pass through the apparatus operated by rectified current, but is expended in heating the solution. This loss is largely dependent upon the electrode potential at the film, the purity of the aluminium and solution, and its temperature. Where continuous service is required of the rectifier, it is therefore imperative to prevent this initial rise in temperature by the use of water-cooling pipes or radiation of some sort.

This form of rectifier requires the use of a transformer with a secondary of twice the direct-current voltage required, plus the resistance loss. This secondary coil is tapped in the centre, and by virtue of the action of the rectifier this tap remains positive at all times to one or the other extreme terminal. The active electrodes are attached to each of the extreme secondary terminals, the number depending upon the phase of the alternating supply. Owing to the peculiar properties of the films on these electrodes, no appreciable current passes from either to the other. Electrodes of inactive material, such as platinum, carbon, etc., would short-circuit the transformer. Between these active electrodes, but insulated from them, is placed an inactive electrode, preferably platinum. Connected between this electrode as one terminal and the centre tap of the transformer as the other is connected the battery to be charged, direct-current motor or other apparatus to be operated. In operation the current passes from the centre tap of the transformer to the motor, from the motor to the inactive electrode in the rectifier solution to one or the other active electrodes, depending on which is at that instant negative to the centre of the transformer. Inside the rectifier the current, therefore, passes from the inactive electrode first to one, then to the other active electrode, as the alternations of the cycle take place, the centre of the transformer remaining positive at all times. It will be understood from this that one side of the transformer is active while the other is inactive, and then reversed during the next alternation.

Digitized by Google

The regulation of direct current is best attained by placing an adjustable inductance between the transformer terminals and the active electrodes of the rectifier. This regulation can also be very efficiently attained by an inductance in the main alternating supply, or by varying the number of turns of wire in the primary of the transformer. Either form of regulation is, of course, much more efficient than placing resistance in series with storage batteries when charging from 110-volt direct-current mains. It is also a well-known fact that a pulsating unidirectional current is especially desirable for charging storage batteries. Just why it is so is not very well understood, but the fact remains.

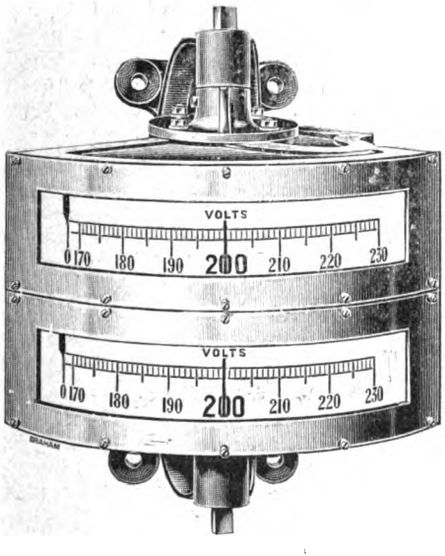
The practical limit of voltage of one cell of the Churcher rectifier is about 50 volts direct current at full ampere load or a difference of potential across the active electrodes of about 130 volts. Somewhat higher voltage may be obtained under favourable condition, but the efficiency is generally much lower because of the increased leakage from one transformer terminal to the othes. Through the use of two cells and two secondaries in the one transformer twice the voltage can be obtained; three cells with three secondaries in the one transformer will give three times the voltage, etc.

Thus it is evident that the Churcher system of rectifiers will deliver any potential of direct current from any alternating current. This statement may seem very broad, but it is perfectly true. Potential, phase, cycles, direct current are all matters of detail, readily worked out by anyone familiar with the system.

TRADE NOTICES AND NOVELTIES.

Nalder Duplex Station Voltmeter.

Messrs. Nalder Bros. and Thompson, Limited, of 34, Queen-street, E.C., have recently placed upon the market a new form



of station voltmeter which possesses some novel and most useful features. It is of the "edgewise type," and consists of two similar instruments fixed together and mounted on a hinged bracket, so that the voltmeters may be turned in any desired direction. These instruments can be illuminated if required. The advantage of such an instrument for paralleling purposes is evident, as it is much easier to determine when both the voltages are the same than is the case by using two distinct instruments. Also, for reading the voltage on each side of a three-wire system, the instrument is a distinct advance on anything that has appeared hitherto. Such an instrument will be highly appreciated by all central-station engineers, as it is of use in both alternate-current working and three-wire continuous-current systems. We have also to announce that Messrs. Nalder Bros. and Thompson have been awarded a gold medal for electrical measuring instruments exhibited at the St. Louis International Exhibition.

Underfeed Stokers.

From Erith's Engineering Company, 70, Gracechurch-street, London, we have a catalogue in which are fully described the principle and working of their patent underfeed stokers. Illustrations included of installations already at work prove that the merits of the system have won for it extensive recognition of a practical order. The good reports which we have from time to time obtained from users confirm the theory of underfeed as being substantially correct, while the above-mentioned firm have shown us that the difficulties attending its practical application have been successfully overcome.

LEGAL INTELLIGENCE.

AREA OF SUPPLY.

The Attorney-General and Others v. The Metropolitan Electric Supply Company, Limited.

In the Chancery Division last week Mr. Justice Farwell had before him an action in which the Attorney-General at the instance of the Willesden Urban District Council sought a declaration that the Metropolitan Electric Supply Company had no power to supply energy within the urban district of Willesden.

Mr. Upjohn, K.C., and Mr. J. W. Greig appeared for the Attorney-General, and the company were represented by Mr. Cripps, K.C., Mr. Jenkins, K.C., and Mr. C. H. Sargant.

The defendant company was incorporated under the Companies' Acts, and its articles of association provided for the unrestricted acquisition of land on which to erect power stations and the supply of electrical energy. By Section 5 of the Act passed in 1889 in favour of the defendant company it was directed that "the undertakers shall not, at any time after the passing of this Act, supply energy or (except for the purposes of this Act) erect or lay down any electric lines or works beyond the area of supply otherwise than under the authority of Parliament or under a license granted by the Board of Trade under the principal Act, provided that where the undertakers were on May 20, 1889, supplying, or under any binding agreement to supply, energy to any premises beyond the area of supply they may continue to supply or supply energy to such premises until Sept. 29, 1890." The area of supply mentioned in the first schedule was a district situated within the administrative county of London. By three subsequent provisional orders as confirmed by Parliament, the defendant company was given similar powers in three other districts all situated in the said administrative county, and each order contained a prohibition similar to that contained in Section 5 of the Act of 1889. In 1898 the defendant company secured the passing of another private Act of Parliament, which authorised them to construct a generating station at Willesden, owing to the lack of land within the areas which they were authorised to supply. This Act contained the following further provisions: "It shall be lawful for the company to hold and use as a station for generating electric current or electrical energy certain lands recently acquired by them in the parishes of Willesden and Acton . . . and to establish and work on those lands plant for generating electrical energy and for other purposes incidental to or connected with their undertaking or business"; and "It shall be lawful for the company to use any of their cables or wires and any mains or cables connected therewith for the transmission of electric current or electrical energy from their works on the said lands at Willesden and Acton to the several distributing stations of the company in their Paddington, St. Marylebone, and Mid-London areas defined by the several provisional orders hereinbefore mentioned and the area in St. Martin-in-the-Fields and the neighbourhood defined by the Metropolitan Electric Lighting Act, 1889, and to use the generating station on the said lands for the purpose of supplying electric current or electrical energy within the several areas or districts over which the company have now powers of supply or over which they may hereafter have such powers under any special Act or provisional order." In 1898 the Willesden Urban District Council obtained powers to supply electricity within its district. In December, 1903, the defendant company commenced to supply the London and North-Western Railway Company, who have sidings adjoining their generating station at Willesden, with electrical energy from the said station. It was now contended that such supply was a violation of the statutory prohibition in the Act of 1889 and the subsequent orders.

Mr. Upjohn, K.C., contended that the prohibition in the defendants' private Act and in the orders was general, and meant that they could supply electricity only within the limits of the statutory districts. The Act of 1898 did not confer any power upon the company to supply electrical energy in Willesden; it merely allowed their generating station to be used for the purpose of supplying the statutory districts and no others.

Mr. Cripps, K.C., said that the defendants were, under their memorandum of association, a company with unlimited powers of supplying electrical energy. Their private Act and the orders gave the company special powers, and put them under special disabilities in certain districts. The prohibition was not a general one, preventing them from exercising their general powers; it meant that the company, as undertakers under the special Act or order, should not raid neighbouring districts and compete with other companies. "Undertakers" meant undertakers under the Act and exercising the powers conferred by the Act, and not the company with its general powers of supply. Alternatively, it was contended that Section 2 of the Act of 1898 was quite general, and conferred upon the company the power of supplying electricity in Willesden.

In delivering judgment, his **Lordship** examined the provisions of the Act of 1889, which defined the "undertakers" as the defendant company. He thought it germane to enquire what the Legislature had in view in passing that piece of legislation. He was entitled to put himself in the position of the Legislature with the knowledge which it had acquired at that time. It appeared that the object of that

Digitized by Google

and similar legislation was to allot certain metropolitan districts to certain companies—sometimes one in a district and sometimes two, but never more than two. Further, it was clear from certain clauses that Parliament took into consideration the financial condition of the companies which asked for statutory powers. The Legislature would naturally take pains to see that every company had sufficient funds not only to carry out the necessary works, but to carry on the undertaking when once they had started active operations, and certain clauses were inserted with that view. Now he was asked to say that the prohibition contained in Clause 5 of the Act of 1889, and repeated in the subsequent provisional orders, was not a general prohibition, but only applied to the company as undertakers under the particular Act. He agreed that some qualification was necessary, and that was that the undertakers, so long as they were undertakers working that particular undertaking, must not supply electricity outside the statutory area—the prohibition was not meant to extend to the company for all time. But he could not interpret the prohibition so as to limit it in the way the defendants wished. Further, the proviso to the clause excluded the idea of limitation, for if this was not a general prohibition the proviso would be unnecessary. The result was that he could not insert limiting words in Clause 5. Then he came to the Act of 1828, the object of which was clear from the preamble. Parliament had thought proper to have a number of electric districts complete in themselves. But in this preamble Parliament was told that the system had broken down and could not work in this particular instance, owing to the increase in the consumption of electricity. The company appealed to Parliament to relax its policy so far as to allow them to erect a generating station for supplying their statutory areas outside those areas. That was the plain meaning of the Act; it was intended to benefit customers of the company within their areas. Section 2 was in general terms, and what it would mean if the company at any time relinquished its areas he would leave to someone else to decide when the case arose. But the section did not authorise the company to supply electrical energy from that station indiscriminately, while Section 16 enabled them to supply their districts, and was consistent with the recitals in the preamble. He could not find anything in the Act giving the defendants power to supply electricity in Willesden. On all these grounds it seemed to him that the company were acting in contravention of legislation, and must be restrained by injunction; but he would suspend the injunction for a month to allow the railway to make other arrangements for a supply of electricity, and if the defendants appealed within a fortnight then it would be suspended until the hearing of the appeal. There must also be a proviso to the effect that the declaration and injunction should not apply in the event of the company parting with its statutory undertakings, as to which event the Court expressed no opinion.

DISPUTED ELECTRIC LIGHT ACCOUNT.

At Aston Police Court on Friday last, William Hunter, cab proprietor, was summoned by the Aston Manor Corporation for the non-payment of £3. 1s. 11d., of which £2. 10s. 10d. was for the supply of electrical energy, and 11s. 1d. for rental of fittings. The electrical supply was from March 5 to May 26, when defendant ceased to use the current.

Mr. R. B. Leech, assistant engineer to the Corporation, stated that the current for which defendant had been charged had been consumed, and defendant was the only consumer who had not paid his account.

Defendant's plea was that the charge was not just, and that the Corporation had not carried out their agreement. He was quite willing to pay on the meter reading.

Mr. Leech replied that the number of Board of Trade units shown on defendant's account was true.

Defendant did not dispute the rental charge, and as to the charge for current, complained that on the bill the state of the meter was not shown.

Mr. Leech said that the gross amount was shown.

Defendant said that on the first reading of the meter he went down the cellar with a youth, and asked what current he had consumed, and the youth replied 32. The meter bore the word "units," and when he received his bill he found that the number of Board of Trade units for which he was charged was 128.

Mr. Leech explained that each division shown on the meter was equivalent to four Board of Trade units.

Defendant asked why the man did not tell him that this was so, and expressed the opinion that that was because he did not know.

Mr. Leech: A number of the consumers engaged an expert in Birmingham. That expert came to the works, and was perfectly satisfied that the meters had to be multiplied by four.

The **Chairman** said the magistrates could see the Corporation's difficulty, but, technically, Mr. Hunter had cause for complaint. The view of the Bench was that if the meter was not intended to register Board of Trade units, proper notice should have been given to the defendant before it was fixed. If that were not done, a man might go on using the light under a wrong impression.

Mr. Leech said the reason Mr. Hunter had not received that notice was that the Council expected the meters to be adjusted to the Board of Trade scale early in February, but some delay occurred.

Ultimately the case was adjourned for a fortnight, and the Bench suggested that the meter should then be brought into court.

STREET OBSTRUCTION.

Mr. R. Fitz-Rogers, manager of the Middlesbrough and Stockton tramways, was charged at Middlesbrough Police Court the other day with allowing tram No. 15 to stand longer than was necessary to take up and set down passengers.

According to the Chief Constable, three officers observed that No. 32 car, which was going along Newport-road in the direction of Stockton, was overloaded. Mr. Fitz-Rogers asked the inspector to remove the excess passengers, but the inspector declined. He, however, would be glad to assist their servants to do so, which was in accordance with his instructions.

Meanwhile, No. 15 car came up from the opposite direction, and Mr. Fitz-Rogers said he would refuse to allow it to proceed until the police cleared the overloaded car of its excess passengers. This the police declined to do, and there was a delay of five minutes, and an obstruction to the street traffic, as a large crowd collected.

The Bench inflicted a fine of 20s. and 21s. costs. Notice of appeal was given.

TRAMWAY FARES.

Montagu John Blatchford, a member of the Town Council, was charged at the Halifax Borough Court, at the instance of the Tramways Committee, with having refused to pay a tramway fare. The amount involved was ½d., the fare from the railway station to the stopping stage near the post office. Originally the stage was opposite the post office, but it has been moved for purposes of convenience about 20 yards nearer George's-square. Mr. Blatchford, who was going to Highroad Well, boarded the car at the old stopping place, and the conductor demanded the fare as from the railway station. The defendant said the case was a trumpery one, and might have been obviated by a little explanation and courtesy. A fine of 1s., inclusive of costs, was imposed.

At the Nottingham Summons Court John Mellers was summoned for refusing to pay a penny tram fare.

Mr. H. W. Day, of the town clerk's department, prosecuted, and said that defendant boarded a St. Ann's Well-road car at the bottom of Market-street and travelled to Parliament-street. When asked for his fare, defendant said that he had got on the wrong car. The conductor said that he must either pay a penny fare or leave his name and address, but the defendant thrust his hand in the conductor's face, causing his mouth to bleed. A constable had to be fetched before the defendant would give his name and address. Mr. Day pointed out how necessary it was that conductors should be protected in the discharge of their duty, and said that each car bore boards plainly stating the destination.

The **Defendant** said that he only got on the car in Queen-street, and added that as soon as he found his mistake he attempted to get off.

A fine of 10s. was imposed.

LINCOLN TRAMWAYS COMPANY.

In the King's Bench Division, before the Lord Chief Justice, Mr. Justice Kennedy, and Mr. Justice Ridley, sitting as a Divisional Court, the case of the Lincoln Tramways Company *versus* Dickinson came on for argument, on appeal by the defendant from a decision of Judge Sherston Baker at Lincoln County Court.

Mr. Hugo Young, K.C., for the defendant, said that the whole question turned on the construction of certain letters. The defendant was asked by the plaintiffs to make a report on their lines. He did so, but was unable to give evidence in the impending arbitration. After his initial fee of 50 guineas had been paid, the plaintiffs alleged that he was bound to give evidence, and that as he had failed to give evidence, they were entitled to recover back the fee they paid him to report. The arbitration never became necessary, as the parties came to an agreement. Meanwhile, however, Mr. Dickinson had declined to give evidence, and the plaintiffs engaged another gentleman, in view of the possible arbitration, paying him also 50 guineas. Plaintiffs sought to recover the fee from the defendant, who contended that there was no contract to give evidence, and that he had done what he was paid for—namely, made an examination and reported on the lines, with a view to assisting plaintiffs to see what price they ought to ask. The county court judge decided in favour of the plaintiffs, and defendant now appealed.

Their Lordships reversed the decision of the Court below, judgment being entered for the defendant, with costs.

COMPANIES' MEETINGS AND REPORTS

BRITISH COLUMBIA ELECTRIC RAILWAY.

The annual meeting of this Company was held at Winchester House on Friday last, Mr. E. L. Evan-Thomas presiding. Particulars of the report appeared in our last issue.

The **Chairman** stated that the gross earnings for the past year had increased since the enlargement of the capital two years ago by 65 per cent. from the lighting and from the railway 40 per cent. Their net earnings had during the same period increased 54 per cent. from lighting and from power 50 per cent. In connection with the anticipated extensions, the engineer's estimate was that the next 6,000 h.p. would only cost an additional £37,000.

The **Hon. M. R. Gifford** seconded the motion, and the report was adopted.

NORTH-WESTERN ELECTRICITY AND POWER-GAS.

The meeting of the shareholders of this Company was held at the North-Western Hotel, Crewe, Mr. T. W. Twyford occupying the chair. The chairman having explained the position of the Company, it was decided to increase the capital with a view to paying off the liabilities incurred in obtaining the two Acts of Parliament, and for other purposes. A sum of nearly £6,000 was promised at the meeting. The

Digitized by Google

Company will make an appeal to the public for capital when the money market is in a favourable condition.

NEW COMPANIES REGISTERED.

Horstmann Gear Company, Limited. — Capital, £1,000. Object: to acquire from S. A. Horstmann, A. Horstmann, E. H. Horstmann, G. O. H. Horstmann, and W. T. Edgar the benefit of a certain existing invention relating to speed gear of motorcars, cycles, and other machines (Patent No. 11,614 of 1904).

Falkirk Electric Construction Syndicate, Limited.—Capital, £100,000. Object: to acquire the control of the statutory rights under the Falkirk and District Tramways Order Confirmation Act, 1901, for the construction of tramways in Falkirk and district, and for that purpose to enter into an agreement with the Scottish Electric Traction Company. Registered office: 37, Castle-street, Edinburgh.

Darlington Wire Mills, Limited.—Capital, £20,000. Objects: to acquire and carry on that part of Messrs. Dunford and Elliott (Sheffield), Limited, business which is carried on at the Skerne Wire Mills, Darlington, formerly known as the Darlington Steel Wireworks, as steel-wire drawers, makers of steel and iron wire, tramway, electric light, and other wire, etc.

Liens Registered.

Electric Law Press, Limited, London, E.C.—Lien registered Oct. 20 for £140 7 per cent. debenture, part of £500; amount previously issued, £100; no trustees; charged on the undertaking and all the property and assets, including the uncalled capital, stock-in-trade, and book debts for the time being.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Vienna.—The Government Railways require tenders for telegraph tape for 1905. Tenders by Nov. 5.

Melbourne.—The Federal Postmaster-General requires tenders for 6,000 yards of telegraph cable. Tenders by Nov. 15.

Crejour (Roumania).—The Municipality require tenders for construction and working of tramways for 50 years by Nov. 7.

Porto Alegre (Brazil).—The term for receiving tenders for an electricity station, already announced, has been prolonged to Nov. 30.

Banza (Spain).—The Municipality requires tenders for the electric lighting for five years. Particulars from the Alcalde, Banza (Jaen).

Guirgia (Roumania).—Tenders are required for the electric lighting of the town. Particulars from the town's secretary. Tenders by Jan. 28, 1905.

Hammersmith.—The Council invites tenders for the supply of (1) extra high-tension feeder mains and (2) draw boxes, frames, covers, etc. Tenders by Nov. 16. See advertisement.

Erith.—Tenders are invited for material and work in connection with the installation of electric light at the Education Committee's offices at Picardy, Belvedere. Tenders by Nov. 11. See advertisement.

Caen (France).—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1, 1905.

Liege.—Tenders are required for the construction and working (concession) of three electric tramways. A deposit of £400 is required. Particulars from the Provincial Government, Liège. Tenders by Nov. 14.

Hammersmith.—The Guardians invite tenders for a complete wiring installation for the electric lighting of their new workhouse and infirmary at Wormwood Scrubbs. Tenders to the Clerk to the Guardians by Nov. 15.

Musselburgh (Scotland).—The Town Council invite tenders for electric wiring and fittings for town hall and offices. Specification may be obtained from the Burgh Surveyor. Tenders to Mr. George Landale, burgh surveyor, by Nov. 5.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Johannesburg.—The Municipal Council invite tenders for two 35-ton electric overhead travelling cranes and transformer pillars and switchgear. Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W., and received by them not later than Dec. 27.

Rotherham.—The Corporation invite tenders for wiring the new isolation hospital buildings in Badsley Moor-lane. Specification and forms of tender at the office of the Borough Electrical Engineer, Rawmarsh-road. Tenders to be sent to Mr. W. J. Board, town clerk, Town Hall, Rotherham, by Nov. 21.

Ballinasloe (Ireland).—The Committee of the District Lunatic Asylum invite tenders for wiring the temporary buildings for 35 incandescent lamps of 16 c.p. each, at a pressure of 200 volts, and the necessary overhead cables to connect same with engine-house, and all else necessary. Tenders by Nov. 14.

Madrid.—An application has been received from Don José Xinxo for a concession for an electric tramway starting from the Plaza Rovira in Gracia and terminating at San Juan de Horta. The notice is published with a view to eliciting any applications for the same concession on more advantageous terms; such applications to be made by Nov. 10.

Craiva (Roumania). — The *Moniteur des Intérêts Matériels* (Brussels) announces that the adjudication will take place at 4 p.m. on Oct. 25 (Nov. 7) at the Mayoralty of Craiova, of the concession for construction and working of a line of tramways (mechanical traction) in the town of Craiova. The duration of the concession is fixed at 50 years. A provisional deposit of £200 is required.

Brussels.—Tenders are invited for the construction of an electric generating station and other works in connection with the establishment of a goods station at Brussels. The estimated cost of the work is about £4,367. A deposit of about £280 is required to qualify any tender. Specifications (price 1s. 10d.) and further particulars may be obtained from M. De Rudder, Administrateur des Voies et Travaux, 11, Rue de Louvain, Brussels.

Burslem (Staffs).—Tenders are invited for the supply and erection of the following electric lighting plant at the workhouse, Chell, for the Guardians of Wolstanton and Burslem Union: (Section A) water-tube boilers, with fittings; (B) feed-water heater, feed pumps, piping, etc.; (C) two 25-kw. steam dynamos and booster; (D) switchboard; (E) cables and wiring; (F) accumulators; (G) arc lamps. Tenders to Mr. J. A. Lowndes, clerk, by 12 noon on Nov. 15.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, London, E.C. Tenders by March 31.

Dundee.—The Town Council invite tenders for the relaying of the present copper strip feeder main throughout the town with insulated cables. Specifications may be had on application to Mr. H. Richardson, A.M.I.E.E., city electrical and tramways engineer, Dudhope-crescent-road, Dundee, on payment of 40s., which will be returned only on receipt of a bona fide tender. Tenders to Mr. W. H. Blyth Martin, clerk to the Council, City Chambers, Dundee, not later than first post on Nov. 12.

Sydney.—Tenders will be received at the office of the Acting Deputy Postmaster-General, Sydney, New South Wales, up to 2.30 p.m. on Dec. 28, for the supply and delivery at the Departmental Stores, Sydney, of telegraph, telephone, and electric light material. Specifications and general conditions may be seen and tender forms obtained at the General Post Offices, Sydney, Melbourne, Brisbane, Adelaide, Hobart, and Perth. Samples may also be seen at Sydney, Melbourne, Brisbane, and Adelaide.

Manchester.—The Electricity Committee invite tenders for the whole of the work required in connection with the wiring for arc and incandescent lighting of Stuart-street generating station. Specifications may be obtained on application to Mr. F. E. Hughes, secretary, Electricity Department, Town Hall, Manchester, on payment of a fee of £2. 2s., which amount will be refunded on receipt of a bona fide tender. Tenders to be addressed to the Chairman of the Electricity Committee, and delivered at the Town Hall, Manchester, by 10 a.m. on Nov. 11.

Brisbane.—Tenders are invited by the Deputy Postmaster-General for the supply and delivery at the Telegragh Office Yard, Thursday Island, of 100 tubular wrought-iron telegraph poles to Specification No. 11 and Schedule No. 51, and also for the supply and delivery at the cable tanks, Thursday Island, of three nauts of submarine cable to Commonwealth Specification No. 8 (Queensland, No. 22) and Schedule No. 50. Tenders by Dec. 12. They must state the time required for delivery; this time will be counted from the date of the notification of the acceptance of the tender. Specifications and forms of tender can be obtained at the General Post Offices, Sydney, Melbourne, Brisbane, and Adelaide. Neither the lowest nor any tender will necessarily be accepted. Tenderers are required to note that Customs' duties must be included in all charges, as per clause 2 of the general conditions. All tenders sent by post must be registered.

RESULTS OF TENDERS.

Falkirk.—The District Tramways Company have accepted the tender of Bruce Peebles and Co., Edinburgh, at £81,000, for permanent way, 8¾ miles, complete electrical equipment, cables and overhead construction, rolling stock, car-shed, etc.

Accumulators.—The A.B.P. Accumulator Company, Limited, Stockton-on-Tees, report the following recent contracts: Handsworth Urban District Council—256 19-plate cells of their standard S. type; Exmouth—230 17-plate cells; St. Andrews, Fifeshire—230 17-plate cells.

Richmond (Surrey).—The Guardians have received the following tenders for the installation of telephones at the workhouse, Grove-road:

	£	s.	d.
Tamplin and Makovski, Limited, Brighton-road, Redhill.	184	3	9
W. Wallace and Co., Limited, 151, Curtain-road, E.C.	169	10	0
Installation Company, Limited (less £1. 5s.)	152	7	0
Reynolds and Co., George-street, Richmond	137	15	0
Electrical Engineering and Maintenance Company, 5, Eastcheap, E.C.	137	0	0
T. Potter and Sons	132	0	0
J. G. Clack, 4, Trafalgar-road, Twickenham	130	0	0
Ditto (alternative)	116	0	0
London and Provincial Telephone Company, 11, Queen Victoria-street, E.C.	122	3	7
Ditto (alternative)	110	16	5
Hemingway and Pritt, Eton-street, Richmond (accepted).	120	0	0
National Telephone Company, Limited	110	0	0

Mortlake.—From the 19 tenders sent in, that of the Brush Electrical Engineering Company, Belvedere-road, London, has been accepted for providing and erecting certain electrically-driven centri-

Digitized by Google

fugal pumps, dynamos, cables, pumping main, etc., for the Richmond Main Sewerage Board.

Barking (Essex).—The Urban District Council have accepted the following tenders for the construction of light railways: D. T. Jackson, Ripple-road, Barking, at £8,117. 4s. 3d., Sections 1 and 1A, 2 and 2A, and 4 and 4A; Dick, Kerr, and Co., Abchurch-yard, Cannon-street, E.C., at £694. 15s. 8d., Sections 3 and 4A.

BUSINESS NOTES.

TRACTION.

Leicester.—The Humberstone-road section has been opened.

Warrington.—Four top covers, at £80 each, have been ordered.

Brighton.—Another electric omnibus has been added to the Brighton-Hove service.

Wakefield.—The light railway connecting Wakefield with Leeds and other places was opened yesterday.

Halifax.—The construction of the length of tramway line from Sowerby Bridge to Styles Triangle has been commenced.

Wrexham.—It is reported that arrangements are in progress for the extension of the tram service from Johnstown to Rhos.

Gloucester.—The total cost of the lately-constructed electric tramways (£147,000 to £148,000) represents a saving of £26,000 upon the original estimate.

Bury.—At its meeting last week the Corporation formally sanctioned the promotion of a Bill in the next session of Parliament for power to construct several extensions.

Falkirk.—The tramway scheme has been hung up owing to the action of a member of the original syndicate in commencing legal proceedings to interdict the new scheme.

North-Eastern Railway.—Sir George Gibb received a deputation on Wednesday, and promised that express electric trains, with first-class carriages, should be run to the coast during the busiest parts of the day.

Sheffield.—As the result of the report upon regenerative control presented by Mr. H. E. Yerbury, the borough electrical engineer, the Corporation have decided to expend a sum of about £160 in experiments.

Flintshire.—It is reported that the project mooted last year of constructing a tramway from Connah's Quay, along the side of the Dee estuary to Holywell, and thence to Mold and Buckley, is not likely to be proceeded with this year.

Cardiff.—The Corporation have passed the following resolution: "That a halfpenny additional fare be charged on the Cathays and Cowbridge-road extensions when opened for traffic." The proposal to introduce advertisements on the cars has been abandoned.

Pontypridd.—The Pontypridd stipendiary magistrate has sanctioned the appointment of Mr. Togarmah Rees, of Newport (Mon.), as surveyor under the Lands Clauses Act to value certain properties which the Council had parliamentary powers to take over for the purpose of the tramway.

Wigan.—The tramways engineer (Mr. Jas. Slevin) suggests that the Council should apply for powers in their forthcoming Bill for the completion of the New Springs route as far as Springs Bridge; also that a clause be inserted in the Bill for the purpose of extending the Pemberton line to Abbey Lakes, Upholland.

Barnet Light Railway.—The Herts County Council have adopted a recommendation of the committee that the county surveyor be directed to prepare the necessary plans, working drawings, and specifications, and that the necessary steps be taken to acquire the lands needed for widening the main road at Barnet, and also for a site for a generating station.

Belfast.—The Corporation have approved the tramways specifications as amended by the consultating engineers, Messrs. Lacey, Sillar, and Leigh, and the town clerk has been instructed to advertise for tenders, to be sent in not later than two weeks from the date of the advertisement. It has been decided to transfer the electric lighting undertaking from the Gas and Electricity Committee to the Tramways Committee.

New York's Underground.—The City Hall to West 145th-street section was opened on the 27th ult. Between 7 p.m. and midnight 127,381 passengers were carried. Express trains are to be run every few minutes during the busy hours of the morning and evening, local trains being dispatched every three minutes. There will be a 10 minutes' service throughout the night. When the further trains now in course of construction are ready the service will be increased.

Batley.—At a meeting of the Tramways Committee, Mr. Paris, of the British Electric Traction Company, attended respecting the construction of the Bradford-road tramways. The committee informed Mr. Paris that they had no objection to the reconstruction of the line as a double line, and were prepared to recommend the Council not to press for the rearrangement of the terms of the agreement between the Corporation and the company as to the maintenance. The company are to communicate with the Council.

West Fife.—In connection with the proposed tramway for the Dunfermline and district tramways it was reported at a meeting of the Kirkcaldy Committee of Fife County Council on Saturday that the road surveyor had been instructed to visit several places where tramways had recently been laid down in country districts before any arrangements were come to. No definite decision was arrived at by the authorities concerned at the conference the other day, but the Kirkcaldy Committee have adopted an encouraging attitude.

Perth.—As already announced in our columns, the municipal tramways are to be converted to electric traction, the consulting engineers being Messrs. Kincaid, Walter, Dawson, and Manville. After a protracted delay, the decision of the Town Council appears to have been accelerated by the exuberance of the experimental motor 'bus, which developed a tendency to gravitate towards the Tay and to precipitate the City Fathers into its rapid waters.

Rowley Regis.—On Wednesday Colonel Yorke, on behalf of the Board of Trade, made an inspection of the tramway which has been constructed by the District Council from Old Hill to Blackheath at a cost of about £28,000. The District Council have leased the line to the British Electric Traction Company, and it is expected that the cars will be running in the course of the next few days, the Board of Trade inspector's pronouncement being highly favourable. It is probable that the complete system, including the lines of the neighbouring authorities, will be opened at the same time.

Birmingham.—At Monday's meeting of the Corporation the necessary authority was given to the Parliamentary Committee for presenting the Bill dealing with tramway extensions next session. Except for the deletion of the Harborne route, the Bill will embody all the routes provisionally agreed upon by the Corporation some time ago, a proposal to withdraw the Corporation-street and Martineau-street route being defeated. We learn that Raworth's Traction Patents have received instructions to equip 40 new cars for the Birmingham and Midland Tramways with regenerative control.

Swindon.—The Town Clerk reported that the Board of Trade had issued their certificate approving of the new tramways, but the certificate was issued on condition that the present canal bridge in Regent-street be only used for one year, except with the approval of the Board of Trade. On the report of the electrical engineer it was resolved that the through service of cars from the corn exchange to Gorse Hill be discontinued, and that all regular cars run to and from the Centre, but that when the traffic demands it an additional car be run through from the corn exchange to Gorse Hill. Two additional cars are to be ordered from Messrs. Dick, Kerr, and Co.

King's Norton.—The Urban District Council have decided to apply for a provisional order for an extension of the tramway from the present terminus to the King's Head at Alcester Lanes End, a distance of six furlongs. The Tramway Committee's report stating that they had passed a resolution rescinding the appointment of a sub-committee to confer with the city of Birmingham in reference to the future working of the trams in the Council's district, and recommending that a special committee be appointed with full power to negotiate with the Corporation, has been approved. This new committee will also prepare and submit a special report as to the present position of all the Council's negotiations as to the future working of the tramways.

Croydon.—At the last meeting of the Town Council the Tramways Committee recommended in connection with the extension of the tramway system to Upper Norwood that powers be sought for a further extension from the borough boundary at Church-road, Upper Norwood, along Crystal Palace-parade, and terminating near the high-level entrance to the Crystal Palace. This extension will be partly within the urban district of Penge and partly within the metropolitan borough of Camberwell. Alderman Taylor, in moving the adoption of this report, referred to the questions asked at a previous Council meeting with regard to the cost of the extensions. The whole of the tracks would cost £70,000; the electric equipment, £25,000; enlargements and new depôt, £20,000; 40 cars, £30,000; contingencies, £10 000; streets improvement, £25,000. The total would come to £180,000. The report was adopted.

Newport.—An informal trial trip was run on the Stow-hill section on Tuesday. The large party included several members of the Corporation, and Messrs. R. H. Haynes (borough engineer). H. Collings Bishop (electrical engineer and tramways manager), L. D. R. Du Verge (deputy electrical engineer and tramways manager), and Fox (deputy borough engineer). The trip gave every satisfaction. The cars which the Corporation intend running on the Stow-hill route are of the latest design, and can carry 55 passengers. They have very powerful motors, and are fitted with a hand brake, slipper brake, a rheostatic brake, and a running back brake, the latter being intended to prevent the car from attaining any speed in a reverse direction. During the trial it was proved that any one of these brakes is sufficient to hold the car on the steepest part of the gradient, while, if necessary, they can all be applied at the same time. The Board of Trade inspection will probably take place in a day or two.

London County Council.—The Highways Committee recommended (*a*) that expenditure on capital account of sums not exceeding £19,280 in all be authorised in respect of (1) the erection of the superstructure of the first portion of the Streatham car-shed required in connection with the electrical working of the London County Council tramways, and (2) the execution of paving works, the laying of rails, and the construction of conduits in and in connection with the car-shed; (*b*) that the erection of the first portion of the Streatham car-shed be carried out without the intervention of a contractor, and that the drawings, specifications, and estimate of £16,180 be accordingly referred to the Works Committee for that purpose; (*c*) that the paving works, the laying of the rails, and the construction of the conduits required for the first portion of the Streatham car-shed be carried out by the Council's permanent-way staff under the supervision of the chief officer of tramways. The committee also recommend that powers be sought to divert the route of the Lewisham and Forest Hill tramway, on the ground that the route selected would entail a large amount of street widening. As the result of a petition from the local tradesmen, the Lewisham Borough Council will probably make representations to the Council with a view to an extension of this line. In regard to the Edgware-road station of the Baker-street and Waterloo Railway, the committee recommend that the plans submitted in regard to entrances and exits

Digitized by Google

be provisionally approved. The Islington Borough Council have decided to offer no opposition to the overhead system on the Moorgate-street to Manor House route.

Bradford.—At a special meeting of the Bingley District Council a report was given of an interview held between representatives of the District Council and a sub-committee of the City Council on the proposed extension of the city tramways from Allerton to Wilsden. The project has been mooted by the residents of Wilsden, and they have secured the promise of the land required for the widening of the road from Allerton to the city boundary at Wilsden free of cost, and have good hopes of securing that required for the remainder of the route (within the Bingley district) to Ling Bob, if an undertaking can be secured for the extension of the tramways to that point. The Bradford sub-committee asked that Bingley should bear half the expense of widening the road in the city to the Wilsden boundary, the total cost of which is estimated at about £5,000, and suggested that Bradford would bear half the cost of the improvement forward to Ling Bob, this part of the work being estimated to cost £1,000. In other words, the Bradford proposal was that the two authorities should be at the joint expense of the highway improvement. The Bingley Council decided that these terms could not be accepted, but expressed willingness to widen the portion of the road in the Bingley district if an undertaking were given that the tramways would be laid to Ling Bob, and on condition that the Wilsden people were able to secure the land required free of charge to the Council.

Aston.—At the meeting of the Council on Friday last the Public Works Committee reported that the work of reconstructing the Lichfield-road tramway was proceeding. It was hoped that it would be completed at the beginning of this week. The committee were continuing the negotiations with the railway company in reference to the rebuilding of the Aston Station railway bridge. Cars are now running to Witton, both up the Witton-lane and round Trinity-road, and also along the Victoria-road to Six Ways. The committee have decided to issue 1d. return fares for workmen along the Victoria-road and Aston Cross route. The same will be done with regard to Witton and Aston Cross, and also in the portion between Salford Bridge and the Cross. Halfpenny fares for children will probably be instituted, but the question of such fares for passengers generally is in abeyance. The men on the steam cars are qualifying in order to take positions on the electric cars. Colonel Yorke, R.E., on behalf of the Board of Trade inspected the system on Wednesday. A large party, including several members of the Corporation, Mr. G. Conaty, Mr. Barling (Birmingham Electric Traction Company), Mr. R. Green (consulting engineer), Mr. Lawson (electrical engineer), Mr. G. Trentham (contractor), Mr. F. W. Richardson (deputy surveyor), and Mr. Foster (electrical engineer to the Council), participated in the trial trip. The inspection commenced from Aston Cross, and in a double-deck car the party proceeded along Park-road and Witton-lane to the depôt. From here the car was taken along Witton-road, Bevington-road, and Trinity-road to Aston Church. Afterwards the lines in Victoria-road from Six Ways to the Vine, and from there along the Lichfield-road to Aston railway station were traversed. A single-deck car was waiting at the station for the purpose of passing under the bridge, and in this the journey was continued to Gravelly Hill and back to Aston Cross. Colonel Yorke expressed satisfaction at the manner in which the work had been carried out, and granted a maximum running speed of 12 miles an hour along Trinity-road, and of 10 miles an hour along all the other routes.

Tramway Accident.—The Stalybridge coroner held an enquiry last week into the death of a little boy named Thomas McCabe, who was killed on the 11th ult. through the derailment of a car belonging to the Stalybridge, Hyde, etc., Board. The jury unanimously returned the following verdict: "The accident was due to the slippery state of the rails at the top of Ditchcroft; the driver is exonerated from blame, and is commended for doing his duty." As the driver was completely exonerated from all blame, his narrative of the accident will doubtless give a very fair account of how it occurred: "I pulled up at the corner of the Guide Post for the guard to set right the switch and loop, and got round the curve all right, but in order to do so I had to apply sand to the rails on account of the wheels skidding. On the way from there to Park-hill I noticed the wheels were greasy, and about twice I used sand up to the stopping place at the top of Ditchcroft. The sand acted. When at the stopping place I brought the car to a standstill with the power brake, but could not tell for how long. Upon receiving a signal to start, I placed the controller of power brake from the fifth notch to the third notch, released the hand-brake, and applied sand to the rails. There did not appear to be any effect from the power brake, and I continued to use sand by means of the hopper. Still there was no effect, and I bent down with the sand bag in my hand and threw sand on the rails, and whilst in that position I could not hear the wheels revolving. I had left the power brake at No. 3 notch during the time I was down on the step, and as soon as I noticed that the car was gliding like a sleigh I returned to the brake, took off the power brake, and momentarily placed the controller to the first notch of power to release the wheels. At this time I was quite certain the trolley was on the wire. I continued to use the sand hopper. The brake was absolutely useless unless the wheels would revolve, but I cannot say whether I released the wheels after my attempt. The car was then going at a great speed. I looked down the road to see if anything was in the way, and I noticed a woman running, and a horse and lurry near the Royal Oak. I then placed the power brake on the second notch, then a third notch, and yet there was no effect. We were then about to enter the curve, and I reversed the motor as a last resource, but this had no effect. I seized the handle of the hand brake, and I remember no more until after the collision, except that the car jumped." From other evidence it appeared that the car left the rails at the curve opposite the Royal Oak. After going at a great speed down the hill it ultimately dashed into the house at the corner of Hartley-street, where the deceased lad was sitting. The driver also sustained considerable injuries.

Newcastle.—The following letter from Mr. Le Rossignol was read at the meeting of the Corporation: "Gentlemen,—At the meeting of Council held on Wednesday last, Oct. 26, a discussion arose upon the letter which I had asked to be read, and in that discussion Alderman Newton is reported in the Press to have made the following statements: (1) horses had been bought and the committee knew nothing about; (2) motorcars had been bought, also without authority; (3) cars were built, although they had an ample supply of cars, simply in order to give men in their employment permanent work; (4) the increase in Mr. Le Rossignol's salary was given under misinformation—he might use a stronger word. Regarding the first statement, on April 26, 1901, the committee by minute approved of the plans for the reconstruction of the sheds at Haymarket and Gosforth, these plans showing stables, etc., for horses and on April 26 instructed me to carry out the work. On May 8, 1902, the committee confirmed the special minute of the Finance Sub-Committee of May 7, 1902, sanctioning the purchase of the first six horses of the stud, and every horse since purchased has been passed in the ordinary way through the pay bill which comes before the committee of which Alderman Newton is a member. On Oct. 20, 1902, the committee, after a survey on the spot, 'instructed the general manager to prepare and submit to them plans for stables at Byker with about four stalls and two loose-boxes, a shed in which to keep the tower repairing wagon and carts,' and on Nov. 6, 1902, instructed me to proceed with the work of construction. In July, 1903, I reported to the committee and Council in my annual report that the Tramways Committee then had 15 horses and the necessary carts, vans, and did their own carting work. In face of this it is idle for Alderman Newton to assert the committee's ignorance. As regards the second statement, that motorcars had been bought, also without authority, the minute of the Tramways Committee meeting of May 22, 1902, states, 'It was agreed that the general manager should purchase a small motorcar to be kept at the power station in readiness for use of officials.' This is the only motorcar the committee possess, but one motor tower wagon has been bought by the committee under their minute of June 12, 1902. As regards the third statement, that 'cars were built although they had an ample supply of cars, simply in order to give men who were in their employment permanent work,' the minute of the Tramways Committee meeting of July 10, 1902, states 'the general manager was instructed to submit designs of proposed new cars, and after the design had been approved, to get the 40 additional cars built.' Only 20 additional cars were built by me under this minute, and the committee's minute of May 12, 1904, instructs me to push on as quickly as possible for race week the construction of the new cars then building. All the cars the committee at present possess, and perhaps more, will be wanted to maintain a proper service next race week. As regards the fourth statement, 'the increase in Mr. Le Rossignol's salary was given under misinformation—he might use a stronger word,' I can only refer to the Council proceedings of Jan. 13, 1904, and repeat what I stated in my letter to the Council that 'during 1903 I had the heavy work of designing and constructing all the extensions to the power station, pumping station, car works, car-sheds, and lines authorised by the 1902 Act, thereby saving you £4,000, which the city otherwise would have had to pay in fees. For this service the Corporation unanimously granted me an increase of £100 a year in my salary, and I very naturally regarded this increase of salary as evidence of the confidence of the members of the Corporation had in me, and also as a tangible proof of the satisfaction which my work had given.' The Council ought to remember that this increase was given after I had been four years in their service. I think the Council will agree that, as I cannot answer for myself in this chamber to Alderman Newton's inaccurate statements, it is only fair that this denial should have the same publicity as his accusation received." Alderman Newton intimated that, so far from modifying anything he had said, he could greatly amplify it. The letter was referred to the Tramways Committee.

LIGHTING AND GENERAL.

Stockton.—The Town Council have resolved to extend the electric light cable to Hartburn.

Hessle.—The Urban District Council intend to apply for an electric lighting provisional order.

Goole.—An application has been made for a further extension of time of the Urban District Council's electric lighting order.

Northwood.—The Northwood Electric Light and Power Company are about to lay their mains in the chief roads in Northwood.

Belfast.—The electrical engineer, Mr. V. A. H. M'Cowan, will report at the next meeting with regard to a short extension of a main.

Eastbourne.—The Council intend to apply for a provisional order authorising them to supply electric energy in the parish of Willingdon.

Bacup.—The Lancashire Electric Power Supply Company are about to proceed to open up the streets and lay the trunk mains within the borough.

Removal.—The Johnson-Lundell Electric Traction Company have removed their offices to their factory at Spencer-street, Southall, Middlesex.

Barton.—The Lancashire Electric Power Company intend to apply for a provisional order to supply electric power in the Rural District Council's area.

Gillingham.—Sanction has been obtained to the proposal of the Town Council to borrow an additional £19,754 for the purpose of electric light extensions.

Woolwich.—The Council have resolved to apply for a provisional order authorising the Council to supply electric light and power throughout the borough.

Digitized by Google

Wimborne.—The Rural District Council will support the Bournemouth and Poole Electric Supply Company's application for an order to supply the district with electricity.

Llangollen.—The Urban District Council are about to consider a petition from ratepayers for an extension of the Llangollen electrical light installation to include Church street.

London County Council.—On Tuesday it was agreed to lend the Battersea Borough Council £11,314 for electric light installation and meters. Several notices to lay mains were agreed to.

Barnsley.—In consequence of the Electricity and Lighting Committee's annual inspection of the public lamps in the borough, a number of additional lamps are to be placed in various streets.

Llanelly.—The Urban District Council are still considering the electric light and traction question. It appears that Mr. J. C. Howell, electrical engineer, Llanelly, has been asked to report.

Award.—We are informed that Messrs. John Davis and Son, Limited, Derby, have been awarded both a gold medal and a bronze medal for their special surveying and mining instruments exhibited at the St Louis Universal Exhibition.

Barnstaple.—An articled pupil has been accepted at the electric light station on the following terms: that a premium of £100 be paid in respect of the pupil, that he serve three years, and that he be paid £20 the second year and £40 the third.

Longton.—The number of units generated for the three weeks ended Oct. 15 was 7,525, against 6,833 for the corresponding period of last year, being an increase of 10 per cent. During the past three weeks 168 additional lamps have been fixed.

Stock Exchange.—Application has been made to the Stock Exchange Committee to allow the Calcutta Tramway Company's further issue of 2,732 ordinary shares of £5 each, fully paid, Nos. 102,269 to 105,000, to be quoted in the official list.

St. Marylebone.—An agreement has been prepared between the Council and the trustees of the Emmanuel Schools for the acquisition of the present site of the schools, a portion of which is required immediately for the purposes of the new generating station.

St. James's and Pall Mall Electric Light Co.—The amount of electricity sold by the company for the quarter ended Michaelmas is returned at 1,338,880 units, estimated to produce £19,873, as against 1,277,469 units, which produced £20,652, for the corresponding period of last year.

Croydon.—The County Council have instructed the General Purposes and Sanitary Committees to make provision in next year's estimates for the installation of electric light in place of gas in all those buildings that are under their supervision other than those they have already decided to instal.

Loughborough.—On Saturday afternoon a trial run of the plant at the new electricity power station was made with satisfactory results, and on Monday the station commenced supply to Messrs. Morris and Bastert, at the Empress Works, with current for motive power as well as lighting. Only one engine has been put down, and the public supply will not be available for some time yet.

Swindon.—The proposed feeder cable to the Gorse Hill district is to be laid in the conduits as early as possible, at an estimated cost of £380. On the report of Mr. Griffin, it has been resolved that a Lancashire boiler be put in at the electricity works. The last monthly report of the electrical engineer shows 245 consumers connected, as compared with 114 a year ago, and 157 street lamps, as against 79 last year.

Bradford.—The work of fixing boilers and electrical plant has been proceeding for some time at the Sunbridge-road destructor, and the actual generation of electricity has now begun, although the installation is not yet completed. A 300-kw. set is now at work, and the current generated is being used for lighting. The ultimate intention is to use it for traction purposes, which will probably be done about Christmas.

St. Pancras.—It is proposed that, in regard to the laying of cables and service pipes for the supply of electric current, the present arrangement of the trenches being opened up by workmen employed, controlled, and paid by the electricity and public lighting department be continued, but that in future the works department follow up the work of laying down cable and services by reinstating the trenches permanently on the same day.

Mirfield.—An enquiry has been held into an application by the Urban District Council for power to borrow £4,948 for the purpose of carrying out an electric lighting undertaking. It was proposed to charge 6d. per unit for lighting, and 2d. per unit for power purposes. It had been under consideration to obtain the current from the Huddersfield Corporation, but at last it was decided to take it from the Yorkshire Electric Power Company, Limited.

St. Helens.—A scheme of extension of the electricity works, involving an outlay of £8,000, is necessary. The engineer has informed the Council that on two nights last winter the capacity of the station was tested to its utmost, and if anything had gone wrong it would have been necessary to disconnect some of the lighting, or to cut off the supply from one or two sections of the tramways. He hoped they would get through this season without any trouble, but they would be pinched.

Portsmouth.—Application is to be made for sanction to borrow £1,200 to complete the proposed Portsmouth telephone extensions, in addition to the £635 already sanctioned by the Council, and £20,000 to cover future extensions of the telephone system, the estimate being for 1,000 lines at £20 per line. This is exclusive of the extension to Southsea, and the money will only be spent as further extensions are found desirable, which, before being carried out, will be submitted to the Council for approval. The committee anticipate to exhaust this money in two years.

Perth.—The Electric Lighting Committee have adopted Mr. Lambert's report on the extensions necessary at the electric station to enable that department to provide electricity for the tramways. Mr. Lambert stated that a 440-kw. dynamo with foundations costing £3,200, steam-piping £150, tramway switchboard £1,400, and additions to the present switchboard £250 would be necessary, making a total of £5,000. The committee will recommend the Council to call for tenders for this additional plant.

Diesel Engines.—The Mirlees-Watson Company, Limited, engineers and founders, Scotland-street, Glasgow, who are now manufacturing Diesel oil-engines, have issued an illustrated pamphlet describing the engine and pointing out its numerous advantages. They state that over 900 Diesel oil-engines, having a total aggregate power of 45,000 b.h.p. are now in use, and that three Diesel engines made by them can be seen running in their own works driving miscellaneous machinery, cranes and dynamos, and they are highly satisfied with the results obtained from them.

Gloucester.—At the last Electricity Committee's meeting the engineer reported that 101 new arc lamps had been fixed, and presented plans and estimates of the proposed extension of plants at the electricity works, for which a special meeting of the committee will be summoned to consider. At the last meeting of the City Council Alderman Fielding, chairman of the Electricity Supply Committee, said it was yet early to predict, but they had every reason to expect that after paying all expenses, interest, and payment of loans, they would have a surplus on the year's working.

Wrexham.—Arrangements have been made for advances up to £5,600 for electric light extension purposes. The electrical engineer, in his last report, gives the following particulars: Current used for tramways in September, 1904, 11,413 units; September, 1903, 14,442 units; for lighting, etc., September, 1904, 21,511 units, as compared with 23,414 units in 1903; total consumption September, 1904, 32,924, September, 1903, 37,856 units. New consumers connected September, 1904, one, September, 1903, two; total number of consumers September, 1904, 140; September, 1903, 134.

Wandsworth.—The Borough Council have adopted a report of the General Purposes Committee on a scheme prepared by Mr. W. P. Adams for utilising the Tooting dust destructor for the generation of electricity. The committee recommended that the County of London Electric Supply Company, Limited, should be informed that the Council contemplated applying for a provisional order for the supply of electricity in the borough, but before taking steps with that object, they would be glad to learn whether the company would be prepared to hand over to the Council the Streatham area of their undertaking upon terms, and whether they would be prepared to purchase in bulk the electricity generated at the Tooting dust destructor.

Whitstable.—At a special meeting of the Council on Tuesday, Mr. W. C. C. Hawtayne said the cost of lighting the town by electricity would probably be £15,000, as the town was of a straggling nature. The interest on the cost of the installation would be about £940, and the cost of manufacture about 2d. per unit. Taking as a basis an annual sale of 130,000 units, their working expenditure would amount to £1,080, which with the £940 would make a total of £2,020. Against this they would have a revenue of £2,700. This they should be able to do with 250 connections. He advised the Council to apply for a provisional order at once. After hearing the report the Council decided to adjourn the discussion until the November meeting.

Awards.—Messrs Everett, Edgcumbe, and Co., 151 and 152, Great Saffron-hill, Holborn-circus, have been awarded a gold medal for their exhibit of electrical instruments at the St. Louis Exhibition. We are informed that the Allis-Chalmers Company, Milwaukee, Wis., have obtained the highest honours at the St. Louis Exhibition with each of their three exhibits—steam-engine, electrical, and mining plant. The 5,000-h.p. engine popularly known as the "Big Reliable," and the huge generator built by this company's electrical department, otherwise known as the Bullock Electric Manufacturing Company, each won a grand prize. In the department of mines and metallurgy the Allis-Chalmers exhibit was also awarded a grand prize, the highest honour given by the international jurors. The Bullock Electric Manufacturing Company's grand prize also covered all their alternators, synchronous motors, direct-current generators and motors, and rotary converters. In addition, the Bullock system of multiple-voltage control of motors won a gold medal.

Russia.—The *Journal de St. Pétersbourg* of Oct. 8/21 states that for more than 20 years researches have been made with a view to fixing on a waterfall capable of furnishing sufficient power to supply St. Petersburg with electricity. Hitherto, the most suitable for this purpose appeared to be a cataract in Finland, which it was proposed to utilise for the working of an electric tramway (see Board of Trade *Journal* of Sept. 8, p. 436). Further researches, however, have resulted in the discovery of the Kiviniemi waterfall on the River Voksen (46 miles from St. Petersburg), with energy equivalent to 25,000 h.p. This waterfall is about 45 miles closer to the metropolis than the one in Finland, and is offered for sale at a considerably smaller price. Unless the difficulties of conveying the current prove insuperable, the Kiviniemi waterfall will be purchased. This, remarks the *Journal*, will ensure the supply of electricity to private houses at a moderate rate, a consummation which was held to be impossible so long as the source of power was situated in Finland.—*Board of Trade Journal.*

Dundee.—The Works Committee on Monday considered an application from the National Telephone Company for permission to lay underground cables through several of the city streets. It is understood that there is a great difficulty to cope with underground wiring over a considerable area of the city, owing to the multiplicity of cables for electric and traction purposes, and it was resolved to recommend the Council to sanction the extension of the existing lines, but that no additional streets be opened for the purpose. A report was submitted

Digitized by Google

relative to the proposed establishment of a kiosk to serve the purpose of a telephone call office in High-street, and it was remitted to the committee to ascertain whether a suitable niche might not be found within the line of The Pillars at the Town House.

Village Telephones.—The directors of the Notts and Midland Merchants' and Traders' Association on Monday passed the following resolution: "That this meeting congratulates the Postmaster-General on the experiments now being made with regard to village post offices serving the purposes of telephone call offices, and is of opinion that such service will be of great benefit not only to people residing in villages, but to traders generally; that, considering the arrangement made with the National Telephone Company, it cannot be expected that that company will undertake the extension work; and that a letter be written to the Postmaster-General expressing the hope that the principal villages in Nottinghamshire and Derbyshire may be connected with the existing system at an early date."

Islington.—At to-night's meeting the Lighting Committee will recommend the laying of a low-tension distributing main at a cost of £90. They will also report on an application from the Underground Electric Railways Company, Limited, for a supply of electricity upon special terms for lighting purposes at the tube railway stations in the borough in consideration of a guaranteed load factor of 23 hours per day all the year round. Inasmuch as this proposal has the exceptional advantage of ensuring what would practically be a continuous use of current, the committee recommend that the lowest rate already authorised by the Council for motive power—viz., 1½d. per unit—be charged for the supply of electricity to the Underground Electric Railway Company's stations in the borough where such supply can be taken from existing mains.

Hammersmith.—The Electricity and Lighting Committee in their last report state that the premises of 14 additional consumers, representing a maximum of 300 8-c.p. lamps, have been connected to the mains; that nine consumers have been disconnected; and that the present number of consumers taking current from the mains is 1,511. The borough surveyor has submitted plans showing the proposed third extension of the electric installation buildings, consisting of additions to the boiler-house. It is proposed to carry the structure on steel stanchions, coal bunkers for the storage of 450 tons of coal being provided. For the present the sides will be covered with corrugated iron. The floor provided over the boilers will be used to carry the economisers. A slate roof will cover the boilers, and a corrugated iron roof will cover the coal bunkers, both roofs being provided with glass skylights at top. The estimated cost of the work is £2,000. The cost of providing a new cable and excavating and laying a new pipe for the new workhouse is £1,462. Tenders for these works and for connecting Olympia are being invited.

Tiverton.—At Tiverton Mercantile Association last week the president, Alderman John Thorne, according to the *Western Morning News*, challenged the hon. secretary to produce any minute showing authorisation to the committee to organise an opposition to the present electric light scheme. It would be utterly impossible for public bodies to continue to do public work if at the last moment without any notice opposition were organised and utterly misleading statements made by a body which took no responsibility for its actions. The committee had gone behind the association and misrepresented facts to the Local Government Board's inspector, inasmuch as it had said so many people were in favour of the loan and so many against, whereas its unauthorised canvass was absurd, and not worth the paper it was written on. He was not called upon, and yet his name was on the list. He did not wish to see the association made the laughing-stock of the town by such actions. He moved "that the action of the committee in organising opposition to the application of the Town Council for a loan for installing the electric light was unwarranted, mischievous, and not such as would commend the work of the association to the public generally." Mr. Henson, a member of the Town Council, seconded the motion, which was not carried.

London Gazette.—A receiving order has been made out on creditors' petition in the estate of Arthur E. Brooks, electrical engineer, 110, Cheapside, London. The first meeting will be held at 11 a.m. on Nov. 7 at Bankruptcy-buildings, London. A general meeting of the British Electric Traction (Pioneer) Company, Limited, will be held at Donington House, Norfolk-street, Strand, London, W.C., on Wednesday, Nov. 30, 1904, at 11.30 a.m., for the purpose of having the liquidator's accounts, showing the manner in which the winding up has been conducted and the property of the company disposed of. The South Lancashire Electric Traction and Power Company, Limited, has been wound up voluntarily, and Henry D. Eshelby, of 24, North John-street, Liverpool, chartered accountant, appointed liquidator. A general meeting of the British Schuckert Electric Company, Limited, will be held at Clun House, Surrey-street, Strand, London, on Friday, Dec. 2, 1904, at 12 noon, for the purpose of having laid before the meeting the account of the liquidator, showing the manner in which the winding up has been conducted and the property of the company disposed of. An adjudication order has been made out in the estate of James Marsden, electric fittings manufacturer, 39, Woodcock-street, Birmingham.

Stoke-on-Trent.—The new electricity and destructor works which have been erected by the Corporation have just been formally opened. A combined scheme of refuse destruction and electricity production has been carried out. The streets of the town are lighted with gas from the Corporation's own works, and the electricity supply will be mainly to private consumers for lighting and power purposes. The continuous-current three-wire system, with a pressure of 240 volts between conductors, has been adopted. The engine-room contains two 240-i.h.p. Willans engines direct coupled to 150-kw. Dick-Kerr dynamos. The battery-room contains a battery of 242 Tudor cells having a maximum total capacity of 350 ampere-hours. About six miles of cables have been laid in wooden troughs. The destructor works contains complete duplicate sets of refuse destructor plant, each capable of consuming under average conditions 30 tons of refuse per day. The estimated cost of the whole scheme is £30,640, divided under two heads, that for the electricity works being £17,840, and that for the destructor £12,800. The buildings have been designed and carried out by Mr. A. Burton, borough surveyor, who has also superintended the erection of the destructor plant, and the electrical portion of the work has been directed by Mr. P. J. S. Tiddeman, the Council's electrical engineer.

Ripon.—The Electric Lighting Committee are considering an application from Messrs. Foote and Milne, Limited, Westminster, for consent to the application to the Board of Trade for a provisional order for the district. The firm offer to enter into an agreement with the Council embodying the following points—viz.: (1) The compulsory area to be named in the order to be the same as in the existing order held by the Corporation. (2) The powers to be contained in that order only to be exercised by a company to be approved by the Board of Trade, and in which company residents in the area of supply shall be given the opportunity of subscribing. (3) The maximum price for current to be named in the order to be 7d. per unit. The actual charges not to exceed the following: to the Corporation for lighting, 5d. per unit; to the Corporation for power, 2½d. per unit; to ordinary consumers for lighting, 6d. per unit; to ordinary consumers for power, 3d. per unit. (4) The Corporation to have the right to requisition the company to lay down distributing mains for the purpose of a general supply throughout any street, or part of a street in which the Corporation have the control and management of the public lamps, but such requisition not to be binding upon the company unless the Corporation give a written undertaking at the time of service to take a supply of energy for lighting the public lamps in such street or part of a street for a period of not less than three years; and it shall not be binding upon the company to supply energy to public lamps outside the compulsory area named in the order, unless such public lamps be placed at intervals of not more than 75 yards from each other, or from any existing distributing main of the company.

Cheltenham.—The report of Mr. Swinburne on the history, position, and prospects of the Cheltenham electricity undertaking has been received by the Council, and will come before the meeting on Nov. 9. At the last meeting of the Lighting Committee, Mr. Kilgour submitted a proposal for expending £1,900 in machinery in connection with the tramway extensions. The *Cheltenham Chronicle* understands that the mayor (Alderman Waghorne) and the town clerk have recently paid a visit to London to interview the Local Government Board with reference to the procedure to be adopted for the repayment of the accumulated deficit on the revenue accounts of the electric department, now represented by an overdraft from the bank, but which the Corporation have deprived themselves of the power to place upon the rates. The result of the interview was that the permanent officials conditionally pledged the Local Government Board not to oppose the Council's application for a provisional order, empowering them to raise a loan for the gradual redemption of the debt, but intimated that it must be accompanied by a guarantee that such a thing should not again occur. To this the visitors replied that they would give the pledge of the Council not to repeat this irregularity, but it was pointed out that they could not pledge future town councils of which they would possibly not be members. They therefore suggested the incorporation in the provisional order of powers for the appointment of a chartered accountant as auditor of the borough accounts. This idea also failed to commend itself, and in the end the condition laid down by the Board, if the provisional order is to be carried through, is that the Government system of audit must be applied to all the borough accounts.

Fulham.—The borough electrical engineer (Mr. Arthur J. Fuller) in his recent report on the advantages of opening a workshop recommends a 6in. screw-cutting gap bed lathe for the workshop at the electric lighting works, at an estimated cost of £50, in order that the smaller repairs at present carried out by neighbouring engineers may be carried out by the Council's staff. Regarding the first section of the electric lighting extension scheme authorised by the Council, the borough electrical engineer has submitted a report as set out below as to the date on which the various portions should be ordered: (1) generator switchboard, ordered (estimated date of completion of work, December, 1904); (2) 1,000-kw. Belliss set, December, 1904 (July, 1905); (3) chimney, December, 1904 (July, 1905); (4) boiler-house, buildings, and alteration, including new rectifier room (part ordered), December, 1904 (August, 1905); (5) coal bunkers, elevators, etc., December, 1904 (September, 1905); (6) four boilers and accessories (portion already ordered), December, 1904 (September, 1905); (7) boiler pumps, December, 1904 (September, 1905); (8) condenser, sump, and river work, January, 1905 (September, 1905); (9) wiring motors, March, 1905 (September, 1905); (10) exciter set, January, 1905 (July, 1905); (11) pipes (portion already ordered), February, 1905 (September, 1905); (12) economisers, March, 1905 (September, 1905); (13) turbo-alternator, ordered; (14) extra buildings, (15) connections, and (16) contingencies as required. Provision having been made in the extension scheme approved by the Council for new mains and connections to the extent of £6,000, we are of opinion that the Council would be well advised to adopt the borough electrical engineer's proposals for side street lighting, particularly having regard to the fact that in many of the streets referred to the paving has not yet been laid. It is recommended that electric mains be laid in Finlay-street, Stevenage-road, Harbord-road, Woodlawn-road, Creswell-street, Inglethorpe-street, Chipstead-street, Quarrendeon-street, Studdridge-street, Gliddon-road, Talgarth-road, Glazbury-road, and Palliser-road, as shown upon the plan submitted by the borough electrical engineer dated Oct. 24, 1904, at an estimated cost of £875. It is also recommended that incandescent lamps be installed in the streets as recommended by the borough electrical engineer as and when occasion requires.

PROVISIONAL PATENTS, 1904.

OCT. 24.

22832 **Apparatus or means for automatically operating and controlling electric motor starters, particularly when used in connection with pumps which require to be automatically started and stopped.** The Tangye Tool and Electric Company, Limited, and Alfred Hewson Bate, 11, Burlington-chambers, New-street, Birmingham.

22838. **Improvements in or relating to electric arc lamps.** The Jandus Arc Lamp and Electric Company, Limited, and Adrian Denman Jones, Hartham Works, Hartham-road, Holloway, London.

22839. **Improved method of supporting electric tramway overhead power transmitting or trolley wires.** James William Allen, Abbotsford, Livingstone-road, King's Heath, Birmingham. (Complete specification.)

22903. **Improvements in and relating to controllers for electric circuits.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22904. **Improvements relating to electrical measuring instruments.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

22905. **Improvements in electro-thermic fans.** Frederic de Mare, 72, Cannon-street, London. (Complete specification.)

22908. **Multiple connecting system for telegraphic and telephonic communication.** Oskar Arendt, 216, Friedrich-strasse, Berlin, Germany. (Date applied for under Patents Act, 1901, Oct. 24, 1903, being date of application in France.) (Complete specification.)

OCT. 25.

22914. **Improvements in switch lampholders for electrical purposes.** Harold Ashton, 8, Bull's Head-yard, Manchester.

22915. **Improvements in the construction of single and two-way electric switches.** Clement Brown Folk Olai and Brown and Barlow, Limited, 16, Loveday-street, Birmingham.

22930. **Improvements in insulated bolts for electric tramway systems and the like.** James Haydock and Thomas Smith Jones, Penny Bank-chambers, Halifax.

22944. **Mercurial, electrical, and hydraulic automatic gas extinguisher in cases of fire by accident or otherwise and of steam or water.** John Poyzants Pavis and William Henry Edwards, 16, Lyndhurst-road, Peckham, London.

22959. **Improvements in electric incandescent candle lamps.** Arthur William Pitt, 34, Carmenia-road, Balham, London.

22963. **Improvements in connection with vacuum brake apparatus for electrically-operated and other trains.** James Gresham, Harry Edward Gresham, and George Kierman, 18, Southampton-buildings, Chancery-lane, London.

22964. **Improvements in gas or vapour electric apparatus.** James Reid Baker, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Nov. 6, 1903, being date of application in United States.) (Complete specification.)

22966. **Improvements in the construction of dynamo and like brushes.** Frederick John Chaplin and Robert Chaplin, 77, Colmore-row, Birmingham.

23001. **Improvements in automatic electric switches.** William M. Scott, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

23009. **Improvements in or relating to intercommunication telephone systems.** Isidore Bernard Birnbaum and Herbert George White, 322, High Holborn, London. (Complete specification.)

23015. **Improvements in devices for automatically switching electric cars from one line to another, also applicable for other vehicles running on rails.** Robert Franklin Jones and Charles Joseph Jones, 6, Lord-street, Liverpool.

OCT. 26.

23027. **An improved terminal for resistance coils.** John Arthur Hirst and Percy Smith Brook, the Northgate Electrical Engineering Works, Victoria-road, Chester.

23031. **Improvements in fuse heads for electric blasting.** Frederick Render, 6, Bank-street, Manchester. (Complete specification.)

23032. **Improvements in hangers or cars for electric trolley wires.** Levi Thomas Allen and Richard Edgar Sharples, 6, Bank-street, Manchester.

23050. **Improvements connected with electric railways.** Oscar Sayle Gill, 139, Dale-street, Liverpool. (Complete specification.)

23056. **Improvements in electrical switches particularly applicable for use on motor cycles and the like.** Charles Walter Hathaway and Triumph Cycle Company, Limited, 18, Hertford-street, Coventry.

23064. **Improvements in switches for reversing the current in electric motors.** George Herbert Whittingham, 52, Chancery-lane, London. (Date applied for under Patents Act, 1901, Oct. 29, 1903, being date of application in United States.) (Complete specification.)

23090. **Improvement in methods of increasing the effective radiation of electromagnetic waves.** John Stone Stone, 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, Oct. 30, 1903, being date of application in United States.) (Complete specification.)

23093. **Improvements in contact breakers for overhead systems of electric traction.** Herbert Victor Mitchell, 55, Chancery-lane, London.

23094. **Improvements in and relating to shields and projectors for X-ray tubes.** Charles Wray Maunsell and Frederick Rowland Butt, 70, Chancery-lane, London.

23095. **Thermo-electric generators.** Franklin Wise Howorth, 46, Lincoln's-inn-fields, London. (William Edwin Haskell, United States.) (Complete specification.)

23097. **Improvements in electrical measuring instruments.** Guy Carey Fricker, 46, Lincoln's-inn-fields, London.

23109. **Improvements in and connected with electro-capillary apparatus.** James Tarbotton Armstrong and Axel Orling, 61, Chancery-lane, London.

OCT. 27.

23118. **Electromagnetic device for automatically applying sanding apparatus on electrically-driven vehicles.** Mark Cummins, 8, Peel-terrace, Chester-road, Old Trafford, Manchester.

23128. **Improvements relating to the trolley pulleys of electric tramcars and the like.** Samuel Richardson Thompson, 55, Market-street, Manchester.

23150. **Improvements in apparatus for the distribution of alternating electric current.** Arthur Francis Berry, 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Oct. 29, 1903, being date of application in France). (Complete specification.)

23165. **Improvements relating to electric gas igniting and extinguishing apparatus.** George Hill, 6, Bream's-buildings, Chancery-lane, London

23182. **Improvements in electric fire-alarms.** William Butterworth Hopkinson, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, April 15, 1904, being date of application in United States.) (Complete specification.)

23201. **Improvements in or connected with the third-rail insulators of electrical railways.** Edward John Chambers, 7, Staple-inn, London.

23203. **Improvements in contacts for electric controllers, reversing switches, and the like.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23204. **Improvements in electric heating apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23205. **Improvements in and relating to the regulation of alternating electric distributing systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Allgemeine Elektricitäts-Ges., Germany.)

OCT. 28.

23219. **Improvements in the caps of electric lamps, adapters, and similar fittings.** Harold Ashton, 8, Bull's Head-yard, Manchester.

23222. **Improvements in electric stop motions for drawing and roving frames** William Muir, George William Somerville, and Howard and Bullough, Limited, Globe Works, Accrington.

23253. **An improved construction of section insulator for electric trolley wires or the like.** Thomas Ernest Raymond Phillips, 11, Finsbury-square, London.

23254. **An improved construction of trolley head for collecting electricity from electric trolley wires or the like.** Thomas Ernest Raymond Phillips, 11, Finsbury-square, London.

23276. **Improvements in electrical apparatus and methods of manufacturing and operating the same.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23279. **Improvements in electrical resistances.** Hermann Aron 47, Lincoln's-inn-fields, London. (Complete specification.)

OCT. 29.

23302. **Improvements in or connected with magnetic or electromagnetic mechanism.** Louis Heathcote Walter, 92, Victoria-street, London.

23352. **Improvements in and relating to carbons for electric arc lamps and the like.** Otto Hellstern, 35, New Broad-street, London.

23377. **Improvements in dynamos.** Isidor Deutsch, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

23380. **A process for smelting nickel ores in an electric furnace and an improved crucible therefor.** La Société Electro-Métallurgique Française, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Oct. 30, 1903, being date of application in France.) (Complete specification.)

23392. **Improvements in alternating-current motors, also relating to generators and direct-current machines.** Valere Alfred Fynn, 70, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Nov. 17, 1904.

1903.

22758. Voltage-regulated electric system for lighting railway and other carriages, for ventilating, heating, and other purposes. Dalziel.

22858. Electrically-synchronised clocks and the like. Chandler and Bonniksen.

22911. Alternating-current motors. Carolan. (General Electric Company.)

22913. Alternating-current motors and methods of controlling the same. Carolan. (General Electric Company.)

23521. Loose-handle automatic magnetic blow-out circuit breakers. Whipp.

23608. Electric switches. Tomlinson and Lomax.

24799. Electric motor systems applicable to electric railways and like purposes. British Thomson-Houston Company, Limited. (General Electric Company.)

25482. Apparatus for obtaining variable electrical ignition applicable to gas-engines. Mellor.

25527. Electric train-control sytems. British Thomson-Houston Company, Limited. (General Electric Company.)

25591. Induction coils and transformers. Delves, Broughton, and Cole.

25855. Electric switches. British Thomson-Houston Company, Limited. (General Electric Company.)

26851. Voltage-regulating devices for alternating-current electric lines. Fitzi.

27446. Form of mechanical ear for suspending overhead lines or wires especially for electric traction purposes. Rea and Reindorp.

27506. Dynamo-electric machinery. Wright and Midgley.

28192. Ball-bearing for use on motors, dynamos, and other machines. Haynes and Gowing.

28453. Electrical motor-starting switch. Crowther and Horsfall.

1904.

461. Means for securing wires on insulators Benedikt and Macek.

786. Means or apparatus for forming the joints in conduits for electric cables. Sutton and Gregson.

2093. Means for the excitation and regulation of induction machines. Leblanc. (Date applied for under International Convention, Jan. 28, 1903.)

7208. Controlling systems for electric motors. Westinghouse and Aspinwall. (Date applied for under International Convention, May 1, 1903.)

9340. Means for carrying overhead trolley wires of electric tramways. Morris.

11857. Electric switches. Stevens.

12007. Regulating apparatus for automatically maintaining electric accumulator charging currents constant. Akt.-Ges. Brown, Boveri, et Cie.

12643. Control of continuous-current electric motors for use in electric traction. Mégroz. (Date applied for under International Convention, June 4, 1903.)

14526. Electric motor controllers. Barrett.

15382. Sub-station connecting arrangement for telephone systems. Birnbaum and White.

15952. Electrode for electrical accumulators. Berg. (Date applied for under International Convention, July 18, 1903.)

17046. System of electric traction for railways and tramways. Marshall.

18098. Wireless telegraphy and apparatus for carrying out the same. Dymond. (Ges. für drahtlose Telegraphie m. b. H.)

18181. Telegraph transmitters. Roussel and King.

19561. Trolleys or collectors for electric tramways. Honnette and Gebhardi.

19683. Electric igniters for explosion engines. Eisemann.

20007. Supports for incandescent electric lamps. Romain and d'Ayguesvives.

20278. Electric switch. Hunter and Warren.

20791. Device for supporting electrical conductors. Bettmann and Zapp.

20975. Electric incandescent lamps. Boult. (Ad. Wagner S. Brechtel und Co.)

NOTES.

Wireless Telegraphy.—It is reported that a Bill will be shortly introduced in Canada for the governmental control of wireless telegraphy, the military authorities urging the expediency of such control in time of war.

Willesden Polytechnic Electrical Engineering Society.—A meeting of the above was held on Saturday evening last, when an interesting paper was read by Messrs. Hayman and Lawrance on the subject of the lighting and power arrangements in the new building. The subject was treated in a very complete manner, and led to considerable discussion. A vote of thanks to the authors concluded the meeting.

Society of Arts.—The Society of Arts will commence its fourth half-century on the 16th inst., when Sir William Abney, as chairman of the society's council, will open the one hundred and fifty-first session with an address. The subjects on which papers will be read at the meetings before Christmas include British trade, canals, the St. Louis Exhibition, patent law, Burma, and street architecture. There will also be a course of lectures on wind instruments, with musical illustrations.

Royal Society.—The council of the Royal Society have bestowed the Copley medal upon Sir William Crookes, F.R.S., in recognition of his extensive researches into spectroscopic chemistry, electrical and mechanical phenomena in highly rarefied gases, radioactive phenomena, and other subjects. Prof. Ernest Rutherford, F.R.S., receives the Rumford medal for his researches into radioactivity, particularly for his discovery of the gaseous emanations from radioactive bodies and their properties. The Davy medal is awarded to Prof. W. H. Perkin, jun., for his discoveries in organic chemistry. Sir Joseph W. Swan gains the Hughes medal for his invention of the electric incandescent lamp and various improvements in the practical application of electricity.

Permanent-Way Institution.—We have received a pamphlet relating to this institution, which was founded by Mr. W. L. Meredith, C.E., and has been doing useful work during the last 20 years in furthering the education of inspectors and others concerned in the permanent-way work of railways by the reading and discussion of papers. There are numerous local sections, and Colonial centres are in contemplation. The council have decided to award gold and silver medals for the two best papers sent in each year. The membership roll has been steadily increasing, and now approaches to a total of 500, which it is hoped to still further increase in the near future. We note that a council meeting will be held at Nottingham on the 12th inst., when new members will be elected and the officers of 1905 nominated. The hon. secretary is Mr. G. E. McLewin, and the London offices are at 9, Gracechurch-street, E.C.

The Effect of Pressure on the Light from an Electric Arc.—In a paper presented to the American Physical Society, of which an abstract appears in the New York *Physical Review*, Mr. W. J. Humphries describes some further tests carried out by him. An electric arc was enclosed in a steel cylinder provided with a quartz window, and the light as produced in air of high pressure examined by means of a Rowland concave grating of 21½ft. focal length. The decrease in wave frequency, detected and measured by Mohler and the author some years ago at the Johns Hopkins University, has been confirmed, and the observations, with the same results, have been extended to many other lines and to a somewhat higher pressure. This work is being done through the aid of the Rumfor Fund, and apparatus is nearly ready by which the investigation can be extended to fully 300 atmospheres pressure if necessary.

St. Louis Awards.—We are glad to see that this country has come in for a considerable share of awards in connection with the St. Louis Exhibition. Amongst those who have been successful in the electrical engineering and kindred branches, we learn that Messrs. Kelvin and James White, Limited, have been awarded a gold medal for the various measuring instruments for switchboard, test-room, and laboratory use exhibited by them. Messrs. Crompton and Co. have gained a similar award. Messrs. Sherard Cowper-Coles and Co., Limited, have been awarded two gold medals—one for electro-chemistry and the other for metallurgy. We also note that Messrs. W. F. Stanley and Co., Limited, 4 and 5, Great Turnstile, Holborn, have obtained a gold medal for surveying and drawing instruments; and that Messrs. William Simons and Co., Limited, Renfrew, have been awarded the grand prize for their exhibit of dredging plant.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on Tuesday afternoon, Sir James Crichton-Browne, treasurer and vice-president, in the chair. H H. the Raj Rana Bhawani Singh Bahadur of Jhalawar, Mr. J. Jennens, and Mr. E. J. Preston were elected members. It was announced that the institution had received a bequest of £100 under the will of the late Miss Harriet Jane Moore. The special thanks of the members were returned to Dr. Ludwig Mond for his donation of £755 for the purpose of erecting a lift from the basement to the second floor of the institution, and any surplus after the completion of the work to go to the research fund. During the recess the entrances and exits of the lecture-room of the Royal Institution have been materially improved by the erection of two covered-in iron staircases, and the widening of the doorways, and the ceiling has been considerably raised. A Christmas course of lectures, adapted to a juvenile auditory, will be delivered by Mr. Henry Cunynghame, C.B., on "Ancient and Modern Methods of Measuring Time" (experimentally illustrated). The dates of the lectures are Dec. 27, 29, and 31, 1904; Jan. 3, 5, and 7, 1905.

Long-Distance Transmission.—California is the home of long-distance high-voltage transmission, which is due to the fact that water power is abundant, while coal is dear and transport facilities few. We have recently received from the Stanley Electric Manufacturing Company, of Pittsburg, a most interesting map showing the long-distance transmissions now actually working in California. From this we note that energy is being transmitted commercially from a number of power-houses over a very extensive area, the present longest distance transmission being 232 miles — from De Sabla power-house to Sausalito, *viâ* Cordelia. A total of 10,000 h.p. is being regularly delivered into San Francisco from the Electra power-house, *viâ* Stockton and Mission San José, a distance of 147 miles. The map is ornamented by some photographs of transmission lines and power-houses, which make it more complete and of considerable interest to electrical engineers. Owing to the cheapness of coal in England, similar long-distance transmission plants are out of the range of commercial politics here. It is worthy of note that these long-distance lines are invariably overhead, which keeps the cost down to a point quite impossible with underground conductors.

Patent Law.—The subject of "The Effect of Patent Law on Modern Civilisation," selected by Mr. C. T. A. Haussen last week for his presidential address to the Civil and Mechanical Engineers' Society, possessed additional interest from the approach of the new regulations which

Digitized by Google

come into force on Jan. 1. A strong plea was advanced for the greater protection of inventors, who have conferred extensive benefits upon the public without in many cases reaping a fair share of the prosperity themselves. Mr. Haussen instanced the case of James Watt, who would have obtained little return for his patent had not the term been enlarged, although owners of property contiguous to railways have had the value of their holdings enhanced enormously. He advocated more liberal legislation so as to render patent grants more secure and to increase their duration, which would give inventors a better chance of making their patents successful. In regard to the duty payable on grants, Mr. Haussen suggested that, in lieu of fixed fees, a tax should be levied upon the income derived, thus furnishing a substantial source of revenue. The advantages of such a system from the inventor's point of view are not quite obvious. It can hardly be the moderate fees payable to the Patent Office for the grant that handicap struggling inventions, while in the case of successful patents the proprietors presumably pay income tax already.

Street-Lighting.—Hearsay evidence, which is not accepted in courts of law, is published freely in the daily Press. We have before us at the present time a cutting from a paper containing an extract from the *Pall Mall Gazette* on the question of street-lighting. The extract is from the letter of a correspondent, and the newspaper which publishes this extract does not trouble to give even the name of the correspondent, so that the value of his opinions may be gauged. We are therefore obliged to draw our own conclusions as to his fitness to give an unbiassed opinion as to the relative merits of gas and electricity for street-lighting. He says: "The fact that Kingsway and Aldwych are to be lighted by gas and not by electricity will come as a surprise to 'the man in the street.' But incandescent gas under pressure has made such headway during the past few years that electricity as a street illuminant has been badly beaten both on the score of cheapness and efficiency. The arc light is ruinously expensive, and when the contract period for lighting the City's streets has expired, incandescent gas will certainly be substituted." We presume that neither the editor of the paper from which we take this extract—the editor of the *Pall Mall Gazette*—nor the correspondent whose epistle the latter journal publishes is aware of the extensive trials, ranging over some years, which have been carried out by Mr. Bradley, the engineer to the city of Westminster. These trials conclusively prove the incorrectness of the views expressed in the above letter, and show that electric arc lighting is the cheapest and most efficient method of illuminating public streets.

Electric Lamps.—The question of the supply of electric lamps by the electrical undertaking is one which has exercised the minds of a large number of central-station engineers. These engineers have to work undertakings in competition with gas companies, and are handicapped by the fact that users of electricity are very prone to buy their lamps in the cheapest market. The result is that their bill for energy goes up, while the light actually obtained from these lamps goes down, and electric lighting is discredited. The obvious solution, which, unfortunately, is not easy of adoption, is that electrical undertakers should supply consumers free with electric lamps of high quality. We have recently received an interesting circular from the City of London Electric Lighting Company, which clearly shows that this matter is appreciated by the engineer of this company. In this circular consumers are urged to use only lamps of the best English manufacture, and the company offer advice gratuitously as to the best makes obtainable. The lamps actually in use will be also inspected by the company's expert free of charge. This move is in the right direction, and is worthy of noting by electric light undertakers who do not already adopt some such methods in order to maintain their position against gas competition. It is the more necessary from the fact that gas companies throughout the country almost invariably undertake the maintenance of incandescent gas-burners. In the same circular an offer is made to carry out insulation tests of consumers' wiring at the low fee of 10s. per test, which includes a report as to any alterations or repairs that may be required.

Electricity and Fire.—The Manchester Corporation recently introduced in its fire department a self-propelling engine fitted with a dynamo, air-pump, and telephone system. This arrangement is intended primarily to assist the fireman in rescuing persons overcome by smoke, and to fight the flames in situations where the absence of such apparatus would render his position untenable. The fireman's headgear comprises a hood, to which is attached an air-pipe, telephone instrument, and an incandescent lamp. Thus provided, our fire guardians can operate in situations where the absence of such an outfit would mean prompt asphyxiation. The fireman obtains a supply of pure air, enabling him to breathe in the foulest atmosphere; the incandescent lamp provides illumination; and the telephone establishes communication with the chief of the party. A great feature of this innovation is that, like most ingenious devices, it is comparatively simple. The additional equipment on the fire-engine is not large, consisting of a small dynamo and the telephone apparatus. The dynamo, which supplies current for eight 32-c.p. lamps, is driven, like the air-pump, from the flywheel of the steam pump. Such an apparatus may reasonably be expected to soon pay for its relatively small cost in the property, to say nothing of the lives, saved. We do not know whether this equipment has yet been called upon to undergo the practical test of a heavy fire, but it certainly promises to be of no little utility. This is evidently the view of some of our Transatlantic friends, and one of the American technical journals frankly asks whether in this instance, at any rate, that land of enterprise cannot learn a lesson from outside. Manchester seems to have scored.

Societe Industrielle de Mulhouse.—This society is offering a number of medals and awards for competition in the early part of next year. The competition is open to the world, but all engineers sending in apparatus or designs should do so before Feb. 15. These should be addressed to the president of the society at Mulhouse. As an example of the awards which are open, we give the following. The society offers a silver medal for the best new application of electricity in the bleaching industry, or in painting or printing. Again, a silver medal is offered for the best essay treating of the comparative expense of installing in a given factory an electric light plant, a gas plant, an acetylene plant, and a water-gas plant. The installation must consist of at least 300 lamps, and the scheme must be worked out in detail. First cost and cost of maintenance should be gone into, and a comparison made of the intensity of the illumination obtained with the different systems. The society also offers a medal of honour and a sum of £20 for the best scheme for controlling a printing machine, or any other machine requiring variable speeds, by means of a three-phase motor supplied at constant frequency and voltage. Certain limits are laid down, as, for instance, the efficiency must not be less than 40 per cent. under any conditions, nor must the power factor be lower than ·4. The horse-power required may be assumed at 10, and the variation of speed about five times the lowest

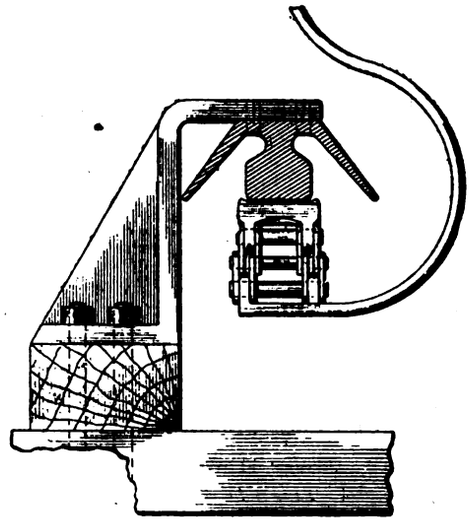
Digitized by Google

speed. In this case, unfortunately, the competitor must have had his devices working for at least six months in a factory in Alsace. The results of this last competition should be interesting to electrical engineers, but we doubt if the value of the award is quite sufficient to secure a representative entry.

Electrical Enterprise in South Africa.—Our contemporary the *British and South African Export Gazette* gives in a recent issue an interesting interview with Mr. R. A. Dawbarn, M.I.E.E, of the firm of Mordey and Dawbarn, who are responsible for the new electrical works of the Johannesburg Corporation. Mr. Dawbarn's remarks on the British manufacturer are worthy of reproduction, and will be appreciated by the hardly-used class of electrical engineers. In this respect Mr. Dawbarn said, speaking of the design and manufacture of single-phase alternating plant: "The English makers are undoubtedly holding their own in regard to design, price, and quality alike, and nowadays they are also quite able to deal with three-phase problems as efficiently as their foreign competitors. The fact is that the Englishman is by no means behind the foreigner, and it sometimes happens that a new idea is quietly utilised in England long before it is suddenly discovered and boomed elsewhere. For instance, you have the Liverpool Overhead Electric Railway, which has been running quite 13 years, though many people are under the impression that this means of locomotion is purely American. Another example is the City and South London Railway's Greathead tunnel for deep-level electric trains, which was the pioneer of its type. The Englishman is not given to advertising his achievements so much as some of his competitors, and the world often accepts the widest claims of adept advertisers without question." Mr. Dawbarn went on to criticise our manufacturers in one respect—*i.e.*, they were content to be poorly represented in South Africa. He added that "American and Continental representatives of machinery houses in the majority of cases possess a far better technical education than their English rivals, and they are consequently able to carry more conviction and to better realise local requirements. I feel convinced this influences British trade very prejudicially." The rest of the interview deals with questions concerning the Johannesburg scheme, treated by us in former issues.

Proposed L.C.C. Overhead Line.—Though the majority of the metropolitan borough councils have proved obdurate in the matter of consenting to the overhead system north of the Thames, it is not likely that the County Council will encounter similar opposition from the Camberwell and Lambeth boroughs in regard to the proposed tramway extension from South Norwood to the Crystal Palace. The Croydon Corporation, whose system is on the overhead principle, are seeking powers to extend their lines so as to provide a service to the Palace, and as the last two or three hundred yards of the line will come within the metropolitan area, they have approached the County Council with a view to the latter body undertaking the construction of this short length, and either leasing it to the Corporation or granting through running powers. At Tuesday's meeting of the County Council the Highways Committee made a favourable recommendation, so that as the two boroughs within whose districts the route is situate are scarcely likely to withhold their consent, the next few months will probably witness the introduction of the overhead system on the lines owned by the County Council. Another matter before the Council was the vexed question of carrying the tramways over Blackfriars and Westminster Bridges and joining them by way of the Embankment. As the City Corporation is apparently disposed to reconsider its attitude on this point, there is a fair chance of the Council's perseverance being rewarded, especially if the trend of events during the past two or three years has had the effect of modifying Lord Halsbury's æsthetic susceptibilities in accordance with public requirements. In such an urgent matter as this, it is surely unnecessary to wait until the Royal Commission has waded its way through the enormous mass of evidence on the whole London traffic problem, particularly when hitherto uncompromising opponents like the City Fathers evince a tendency to recognise both the need and the reasonableness of the proposal.

New Third-Rail Design.—A patent has been granted in the United States to Mr. A. F. Chase for a third-rail design, of which a description, with the accompanying diagram, appears in the *Electrical Review* of New York.



The depending portion of the rail has its widest part at the under-face thereof, and this width is proportionate to the face of a contact shoe, intended to receive the propelling current from the rail. The upper part of the depending portion, which is the rail proper, preferably narrows toward the top into a neck-like form, terminating in a flat top, from which spread outward on each side two oppositely disposed flanges. From these flanges extend wings, which are preferably straight and must incline downward and outward, and are of such lengths as to bring their lower ends in or about the same horizontal plane as the base or contact face of the rail proper. In each of the flanges are boltholes, drilled vertically through the same, to enable the third-rail conductor to be mounted to the rail-hanger. This construction of third rail provides a water-shed over the rail proper, and may be made integral therewith, the downwardly inclined extending wings also protecting the conductor laterally.

40,000-Volt Transmission.—An interesting plant has recently been laid down in Northern Italy by Messrs. Brown, Boveri, and Co., of Baden. The works are situated near Gromo, amongst the Alps, and energy is transmitted some 20 miles to Nombro at 40,000 volts. The reason for this very high voltage was that the engineers wished to get the loss of energy in the line down to 4 or 5 per cent., and to use wires not more than 6·5mm. in diameter. The central station is equipped with three groups of turbo-generators of 750 kw. capacity The alternators are three-phase and work at a frequency of 50. The transformers are connected directly to the alternators without the intervention of any kind of interrupter, and the generator and transformers are connected in parallel on the high-tension side. The transformers are oil-cooled, and the oil is kept cold by means of water circulating through cooling pipes placed in the oil. In each of the three

Digitized by Google

main conductors there are placed three single poles, oil break switches, which act automatically for excess current, and can be operated by hand. As these interrupters are arranged to act simultaneously, there are six breaks in the circuits at the same time when the switches are open. The automatic switches are opened by mechanical means to ensure simultaneous working. The insulators used on the overhead line are of special make, and have been tried up to 80,000 volts in dry air. When the moisture in the air reaches 60 per cent., there is a discharge to earth at 39,000 volts, and when water falls on the insulator there is a slight discharge at 54,000 volts. The insulators are carried on poles 26ft. high, and the wires are spaced 33in. apart. On sharp curves the poles are placed close together, but the mean distance is about 44 yards. The working results from this installation will be of great importance to the profession as a whole. The experience gained at these high voltages under the climatic conditions of Northern Italy will be of special value.

British Mineral Production in 1903.—A report on mines and quarries issued by the Home Office gives the amount and value of the home production of minerals during 1903. The total value of the minerals raised amounted to £101,808,404, a decrease of £5,296,480 as compared with 1902. This decrease, however, is to be accounted for by the fall in the average price of coal from 8s. 2·84d. per ton in 1902 to 7s. 7·93d. in 1903, the output of that mineral being the highest hitherto recorded—viz., 230,334,469 tons, an excess of more than three million tons over that mined in the preceding 12 months. The quantity of coal exported, exclusive of coke and patent fuel, and of coal shipped for the use of steamers engaged in foreign trade, was 44,950,057 tons, an increase of nearly two million tons on the exports for 1902. Germany, France, and Italy each received over six million tons, Sweden over three million tons, and Russia, Spain, Denmark, and Egypt each over two million tons. Adding the 2,055,444 tons exported in the form of coke and patent fuel and the 16,799,848 tons shipped for the use of British and foreign steamers engaged in foreign trade, the total quantity of coal which left the country was 63,805,349 tons. The amount of coal remaining for home consumption was 166,529,120 tons, or 3·930 tons per head of the population; 18,302,240 tons were used in the blast furnaces for the manufacture of pig iron, as against 17,649,137 tons in the previous year. The output of iron ore, 13,715,645 tons, shows a further increase of 289,641 tons, but the value (£3,229,937) is less by £58,164 than in 1902. The ore yielded 4,500,972 tons of iron, or about one-half of the total quantity of pig iron made in the country; 6,314,162 tons of iron ore were imported during the year, 78 per cent. of which came from Spain. Copper, gold, lead, silver, and zinc all show an increase on the figures of 1902 both in the amount and value of the metal obtained, and in the case of tin, although the amount obtained is less, the value is greater. Of the non-metallic elements an increase from 150,000 to nearly a million cubic feet in the output of natural gas at the Heathfield workings is recorded.

Municipalities and the Telephone.—The Postmaster-General received on Monday a deputation of representatives of corporations owning telephones, with reference to the proposed acquisition of the National Telephone Company's system by the Government. Delegates attended from Glasgow, Guernsey, Hull, Brighton, and Swansea. The municipality of Portsmouth were not represented, but telegraphed to say they were in accord with the views of the deputation. The Lord Provost of Glasgow explained that the authorities who had already organised and were working municipal telephones were in a state of considerable anxiety and doubt as to the future, which tended in some measure to restrict their efforts. They were of opinion that, if bought at all, the whole of the National Telephone Company's system ought to be purchased by the Government, and perhaps a solution of the problem would be the granting of a lease for a stated period of years to the great municipalities who had a service working in concert with that of the Government. Alderman Carden (Brighton), in answer to the Postmaster-General, stated that he thought it would be impossible to make it compulsory on municipal authorities throughout the kingdom to take over the telephone system. The Postmaster-General remarked that the effect of that would be that only the profitable undertakings would be worked by the municipal authority, and the unprofitable districts would be left to be worked by the Government, a policy which he was afraid he could not support. He expressed his gratification that the deputation were agreed that, if the National Telephone Company's business were purchased, it should not be done piecemeal, but as a whole. Similarly, any arrangement that might be made, or might be considered advisable, for the transfer to municipal authorities of the powers acquired must be equally in its entirety and not in part, and every municipality would then have to take it over and work its local exchange whether it liked it or not, leaving in the hands of the Government simply and solely the trunk lines. He did not know what Parliament would decide, but personally he should never himself support any view different from that, and he could not see that the transfer of any portion of this business to municipalities would conduce to cheapness or to efficiency. The deputation afterwards consulted with the Postmaster-General in private.

Electricity Vindicated.—The Electrical Contractors' Association is evidently animated by a laudable ambition to remove the firebrand stigma inflicted upon electricity by the indiscriminating reporter. From the official organ of that body we learn that a disastrous conflagration occurred a few days ago at St. Chrysostom's Church, Manchester. An electric lighting installation had been completed in the church a few days before, and, as it happened, the light was switched on for the first time on the day of the catastrophe. The flames spread with great rapidity, and within a few minutes of the discovery of the outbreak all hope of saving the edifice was abandoned. Beyond the bare fact that the electric light had been in use on the day, there was not a vestige of evidence to connect the conflagration with the new installation; but, following the usual practice, many of the papers in the neighbourhood immediately attributed the disaster, more or less candidly, to the electric lighting. The Manchester section of the Electrical Contractors' Association determined that these statements should not go unchallenged. After instituting preliminary enquiries, the association conducted an investigation into the matter in conjunction with the Corporation electrical department. Prior to the current being switched on when the light was used for the first time, a careful test had been made of the wiring, which proved to be completely insulated. Although the fire had left no trace of its cause, enquiry of the rector, verger, and assistants elicited the fact that at 6.45 p.m. one of the double-pole switches was turned off altogether by the contractor's foreman, and through the second double-pole switch a supply to two fittings in the choir only remained. These lights were turned off by the verger in the presence of the cleaners a little after 7 o'clock, some hours before

Digitized by Google

the fire. Thus all circuit wiring from the switchboard onwards was absolutely cut off from the supply, and the mains from the point of supply to the place where they rise through floor to the switchboard are still intact, showing that no fault occurred there. It transpired that a large fire was left in the vestry for the purpose of burning all the rubbish which had accumulated during the alterations, and a gas-ring was in use at the back of the organ for hot-water purposes. The evidence does not prove these to be the cause of the outbreak, but it shows pretty conclusively that the electric light was not responsible for the disaster. The Manchester contractors have rendered a valuable service to the electrical industry, and a few of these investigations will be of great aid in counteracting the unjust aspersions which are so often cast upon electricity.

Municipal Indebtedness.—At the meeting of the Institute of Bankers the other day the president, Mr. J. Spencer Phillips, selected for the subject of his address the question of municipal indebtedness, which has of late come in for frequent discussion in the Press and elsewhere. As is generally known, the sum of this indebtedness approximates £400,000,000, and suggestions have been made that our municipalities are instituting a race with the National Debt. There is, however, still a big margin between the two, and in considering the rapid strides which municipal indebtedness has incontrovertibly made of late years it should be remembered that this has been essentially the period of municipal development. Heavy outlays have been incurred which are not likely to be repeated during the next decade. We do not propose to deal here with the ethical aspect of a comparison between the National Debt, which may be termed a reflection of the battlefield, and municipal liabilities, for which the country has had a substantial return in economic progress; but in considering the criticisms of municipal trading, it is but fair that some discrimination should be shown between its different branches. As to whether music halls, aquaria, and banks should be the subject of such enterprise there may be considerable difference of opinion, but few will deny that a public service such as the tramways comes within its legitimate sphere, and in this department there have been many successes, some of them notable ones. From its past year's revenue Liverpool contributed towards the relief of the rates no less than £25,166 from tramways alone, and altogether local taxation was reduced to the extent of 11½d. in the £ as the result of municipal enterprise. Glasgow and Leeds are other examples which readily occur to the mind. Nor is this the measure of the benefit derived by the public, the other great advantages including improved services and reduced fares, though in the latter respect there is a tendency to adopt the prudent advice recently given by the president of the Municipal Tramways Association. Another point which has to be remembered in considering the growth of municipal expenditure is that local authorities have had imposed upon them certain functions of, financially speaking, an unproductive character, such as education, which exhibits an annual tendency towards expansion. In regard to the Metropolis, Mr. Phillips severely deprecated the extravagant example which it set to the provinces. This is rather a reversal of the usual practice of holding the English capital up as a model of economic stagnation. However, the statements made by Lord Welby the other day should be reassuring to the alarmists, for, notwithstanding the numerous enterprises upon which the London Council Council has embarked, the total of its loans is still considerably less than two years' rateable value. Were municipal indebtedness to continue increasing at the rate it has done during the past decade, it would doubtless be necessary to place some curb upon it, whether by legislation, public opinion, or the common-sense of our local councillors. Perhaps a combination of the last two would effect the object, as public opinion, which so far has not made its voice felt very distinctly in this connection, would probably assert itself if the rates bill became too onerous.

The Temperature of the Arc.—Messrs. C. W. Waidner and G. K. Burgess contribute an article on this subject to the *Physical Review* of New York. After discussing the various phases of the question, the authors give a table, reproduced herewith, of the estimates of arc temperature reviewed by them. From this table it will be seen that the photometric methods based on the extrapolation of Wien's equation show that the "black body temperature of the arc" (pure graphite) is at least 3,750deg. absolute, so that its true temperature must be higher than this; it is not possible to state how much, in the absence of more definite knowledge concerning the departure of carbon from black body radiation. In the light of the best evidence that is at present available it would seem that the true temperature of the hottest part of the positive carbon is between 3,900deg. and 4,000deg. absolute.

Observer.	Absolute temperature of the arc.	Method.
Le Chatelier.	4,370	Photometric: Intensity of red light.
Violle.	3,870	Calorimetric: Specific heat of carbon.
Wilson and Gray.	3,600	Total radiation of copper oxide, empirical relation for.
Wanner.	3,700-3,900.	(Varying with carbons used.) Photometric, in terms of Wien's law.
Very.	Between 3,600 and 4,000.	Wave-length of maximum energy Wien's displacement law: $\lambda m\ T = C$.
Lummer and Pringsheim.	Between 3,750 and 4,200	Wave-length of maximum energy Wien's displacement law: $\lambda\ T = C$.
Féry.	3,760	Total radiation: Stefan-Boltzmann law.
	4,150	Photometric: Wien's law.
Waidner and Burgess.	3,690	Holborn-Kurlbaum pyrometer, Wien's law.
	3,680	Wanner pyrometer, Wien's law.
	3,720	Le Chatelier pyrometer, Wien's law.

As an explanation of the high values found by Le Chatelier and Féry, using photometric methods, the authors allude to the want of monochromatism of the glass used, this circumstance applying specially to the red glasses that are sometimes employed with the Le Chatelier optical pyrometer. Further, the authors point out that the "centre of light" transmission of this glass is higher than that usually assumed from Le Chatelier's early determinations, probably made with a different kind of glass. The authors state that if they are justified in assuming these explanations to be satisfactory, a comparison of the results contained in the table will show, when allowance is made for the experimental difficulties and uncertainties that may arise from varying conditions of the arc (such as current strength, length of arc, quality of carbons, etc.), that the results obtained, dependent as they are on the extreme extrapolation of different laws, are in quite satisfactory agreement, and diminish somewhat the doubt which is always present when we must venture beyond the domain of experiment. The value obtained by Féry for the "black body temperature" of the arc by making use of the Stefan-Boltzmann law for the total radiation of a black body is in most satisfactory agreement with the results obtained by Wanner, dependent on the extrapolation of the Wien-Planck relation, and is nearly identical with the author's own photometric determinations, based on the same relation.

LEEDS, WAKEFIELD, AND WEST RIDING TRAMWAYS.

An extensive system of electric tramways, owned by the Wakefield and District Light Railways Company, has been recently inaugurated. Although there is a considerable mileage at the moment in operation, the scheme is only partially completed, and when the remaining sections and links are finished the system will embrace wide districts round Leeds and Wakefield, including Horbury, Ossett, Normanton, Castleford, Pontefract, Lofthouse, and Rothwell. Eventually it will involve the operation of some 75 miles of single track, linking together, by a frequent service, some of the most populous districts in the West Riding of Yorkshire. The ramifications of the tramways are clearly shown in the accompanying map (Fig. 1), from which it will be seen that the most important trunk line runs from Wakefield to Thwaite Gate, and there joins the Leeds Corporation tramways system. Bearing in mind the recent and important discussions on the subject of joint running powers, it is interesting to note that it has been possible for the company to arrive at an arrangement with the Leeds Corporation under which cars can be run to the centre of Leeds. Such an understanding must result in the greatest convenience, and should materially add to the efficiency of the District Company's system and prove to be a useful feeder to the Corporation tramways.

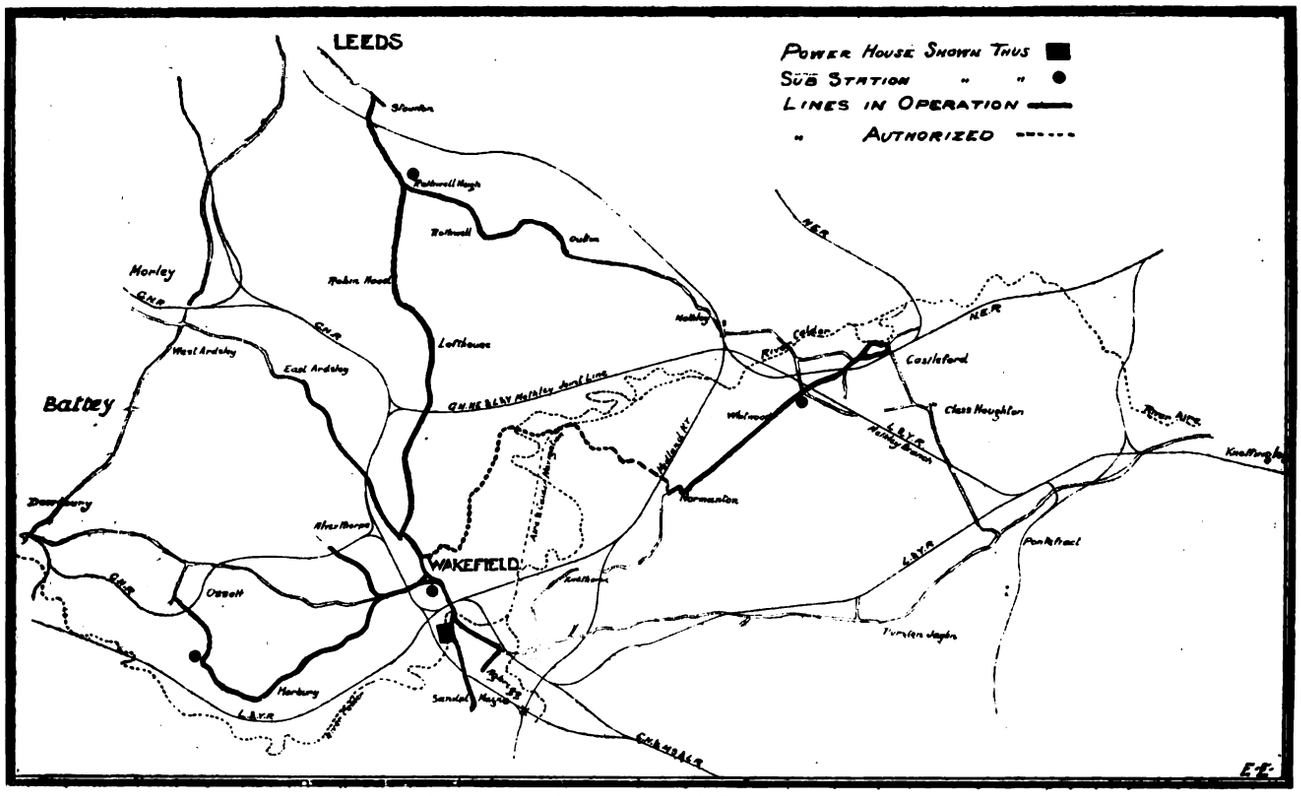

FIG. 1.—Map of Leeds, Wakefield, and West Riding Tramways.

Taking Wakefield market place as the centre, the system branches out into four directions—to Sandal Magna (two miles), to Agbriff (two miles), to Ossett *vid* Horbury (nearly five miles), and to Thwaite Gate (about seven miles). There is, in addition, a most important branch line from the Leeds end of the line through Rothwell and Oulton. A considerable portion of track has been constructed between Normanton and Castleford, a distance of about 3½ miles, and eventually

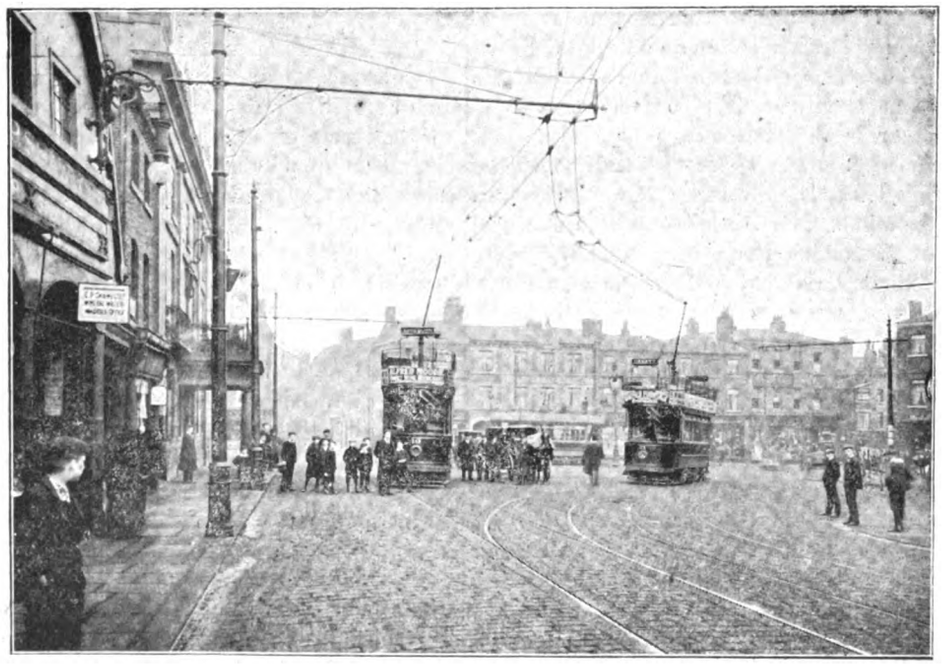

FIG. 2.—Side-Pole Construction, Bull Ring, Wakefield.

Digitized by Google

this would be linked up to the main system. Other lines are in course of construction, the total mileage constructed up to date being roughly 32½ miles of single track. The contract for the whole of the work was given to the firm of Dick, Kerr, and Co., Limited, the consulting engineer for the scheme being Mr. B. D. V. Cooper.

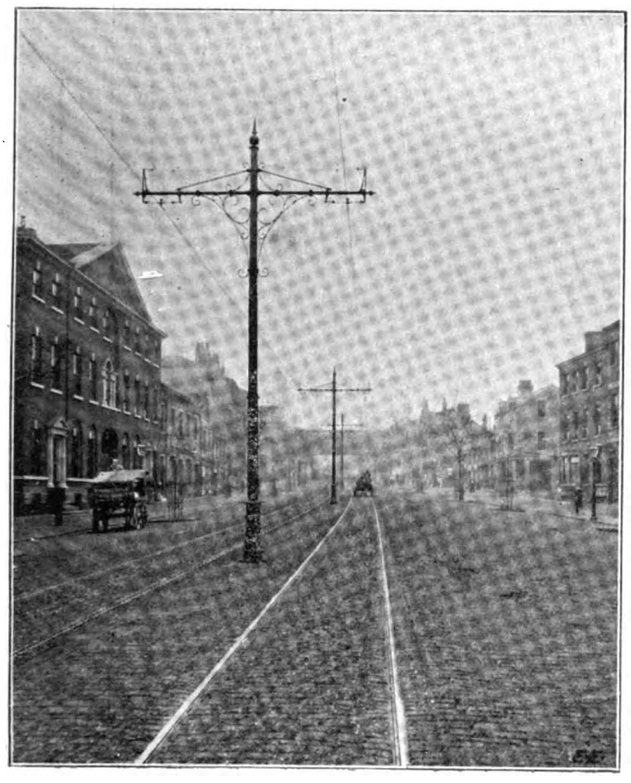

FIG. 3.—Centre-Pole Construction, Westgate, Wakefield.

Such a system obviously calls for high-tension transmission, as it would be, of course, impossible to work all the routes embraced in the extended scheme from one central station. The generating station is situate at Belle Isle, Wakefield, where alternating current is generated at high pressure for transmission to sub-stations, where it is transformed to direct current of 500 volts. One sub-station is in use in Wakefield about one mile from the power station, where three 200 kw. rotary converters have been erected, and another in Rothwell with two 200-kw. rotaries. Later on there will be a third at Castleford, which is about 10 miles from the power station, and a fourth at Ossett.

The total length of tramways at present in operation is approximately 25 miles of single track, laid to a gauge of 4ft. 8½in. The usual method of construction has been employed. On about nine miles of single track the roadway has been excavated to a uniform depth of 12½in. below the upper surface of the rails, to receive an 8in bed of concrete to carry the paving for a width of 8ft. for single track and 17ft. for double track. The roadway between the rails and for an average space of 18in. on either side,

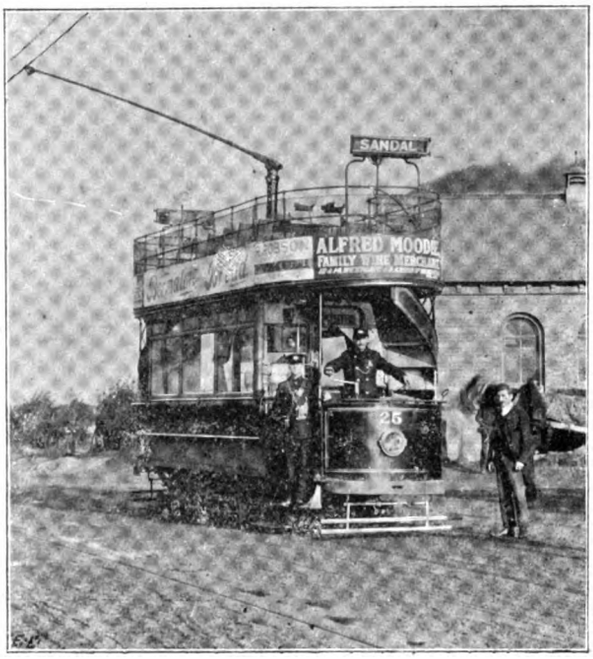

FIG. 5.—Motorcar, Leeds, Wakefield, and West Riding Tramways.

both for single and double track, is paved with granite setts 5in. deep and 4in. wide. In the remaining portion, some 16 miles, the roadway between the rails is filled in with screened macadam. The rails are of the girder type, weighing 94lb. per yard, and are laid in 45ft. lengths, with a proportion of shorter lengths to allow for closures. The rails are generally in accordance with standard tramway practice, 6½in. deep, with a groove of 1⅛in.; they are used as a return conductor, the joints being of the plain type, secured with six-holed fishplates, 24in. in length, and are double bonded with 4/0 Neptune copper pin bonds.

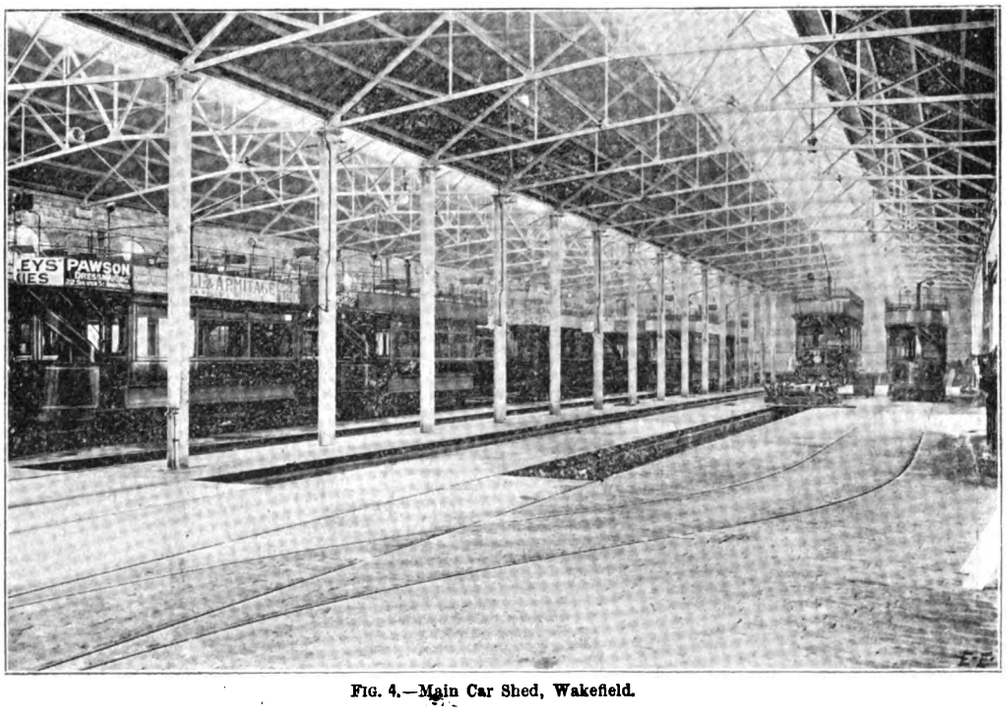

FIG. 4.—Main Car Shed, Wakefield.

Digitized by Google

The construction of the overhead lines is for the most part carried out on the side-pole system (Fig. 2), with bracket arms and flexible suspensions. Centre poles (Fig. 3) are employed only to a small extent. The poles, which have an over-all length of 31ft., and are made up in three sections

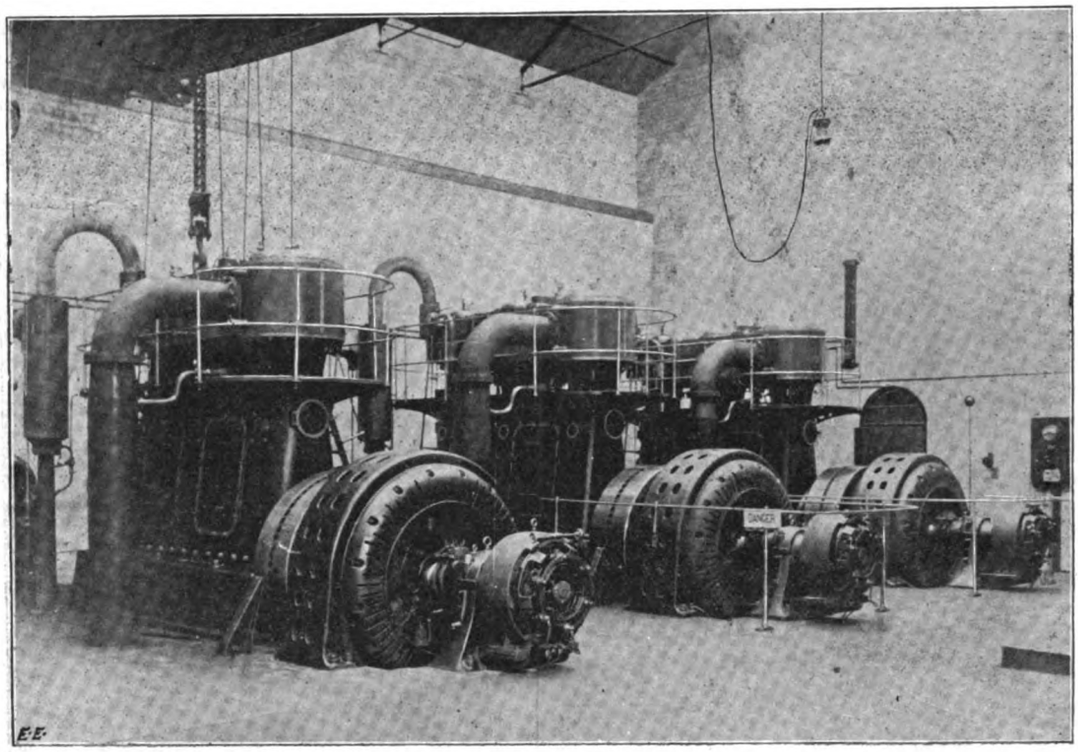

FIG. 6.—Generating Plant, Leeds, Wakefield, and West Riding Tramways Power Station.

of lap-welded mild steel, are erected about 40 yards apart on the straight, and closer on curves, in holes 6ft. deep, surrounded by from 6in. to 9in. of concrete. In towns and residential districts the brackets are fitted with wrought-iron scrollwork of a neat design. The trolley wires are of hard-drawn copper wire, 2/0 S.W.G., having a diameter of ·348in., weighing 1,935lb. per mile, and with a breaking strain equal to 24 tons per square inch. At certain points over the low-tension feeders, feeder switch pillars of the Dick-Kerr standard pattern are erected. Each pillar contains a white marble panel, on which are mounted two 400-ampere quick-break switches, these being connected through vulcanised indiarubber cables direct on to the trolley wire. At all other points the mains are looped into the pole section bases described below. At every half-mile along the route small cast-iron boxes are fitted to the poles, each containing four 150-ampere "no arc" switch fuses. These boxes serve the purpose of dividing the trolley wire into half-mile sections and cross connecting for the parallel running. The cable taken from these connecting boxes up the poles has the same section of copper as the trolley wire, and is insulated with vulcanised rubber.

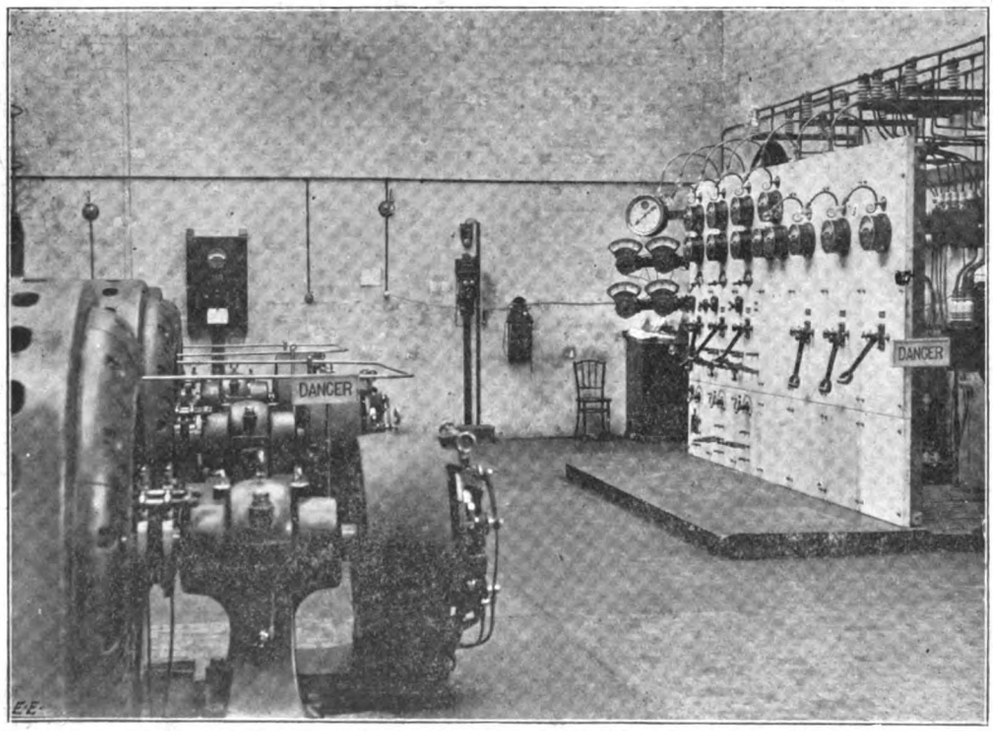

FIG. 7.—Main Switchboard, Leeds, Wakefield, and West Riding Tramways Power Station.

Three car-sheds have been constructed. The principal depôt (Fig. 4), situated at Wakefield, has six tracks, and is capable of accommodating 35 cars. The other two sheds have been built at Rothwell and Castleford respectively. The rolling-stock eventually will consist of 55 electric motorcars of the double-deck, single-truck, reversed stair-

Digitized by Google

case type (Fig. 5), with a seating capacity of 22 inside and 34 outside. The car bodies were built for Dick, Kerr, and Co. by the Electric Railway and Carriage Works, Limited, of Preston. The floor frames are made entirely of oak by 1½in. fixed longitudinally. To prevent sagging, each side frame of the car is trussed by a ⅝in. tension rod attached to the bottom sills. The side and end frames are of pitch pine and ash. The side frames each contain three

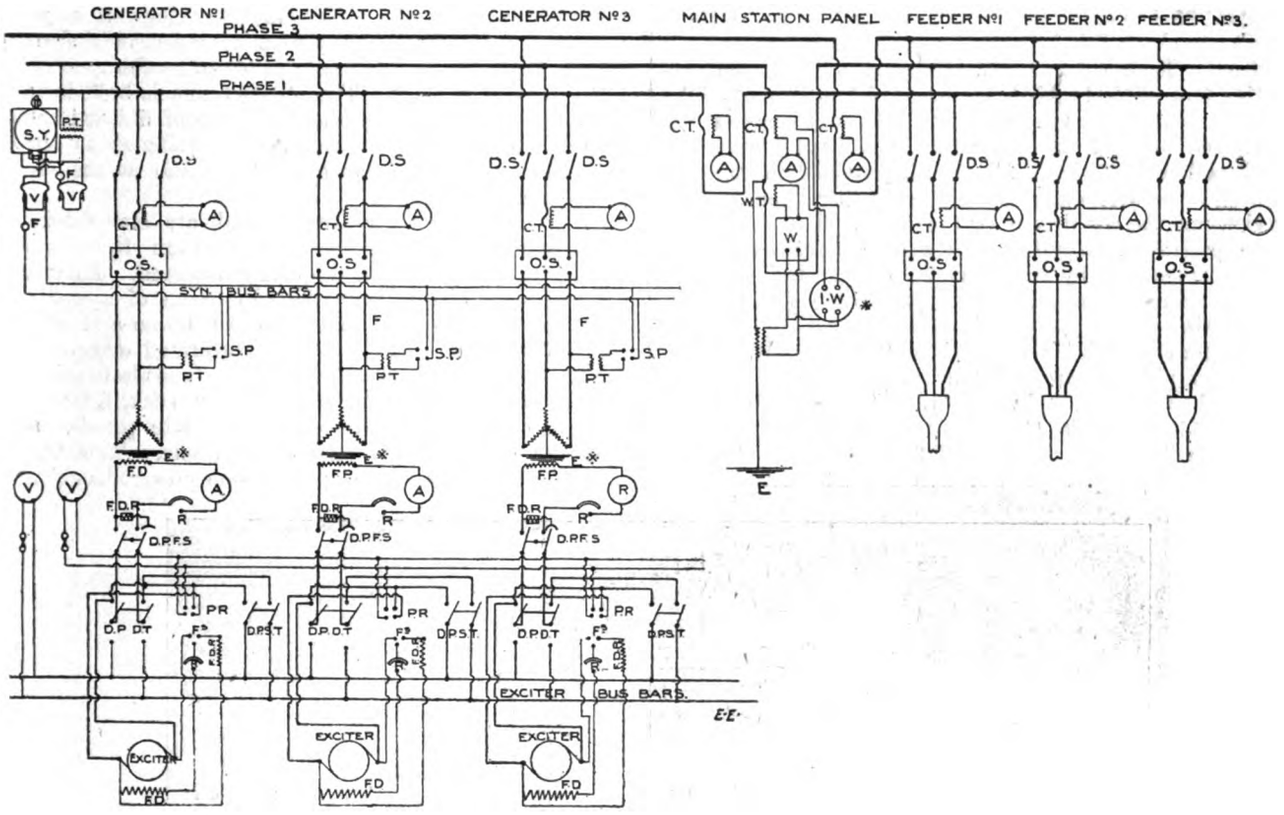

Fig. 8.—Diagram of Connections to Main Switchboard, Leeds, Wakefield, and West Riding Tramways Power Station.

and pitch pine. They are designed to combine the greatest strength and stiffness and minimum weight. Special care has been taken in designing the cars to ensure the interchangeability of all the most important parts entering into their construction. Openings are arranged in the flooring large windows, with narrow pivoted ones above for ventilation. The roof frame is made of ash, the horizontal members being all in one piece without splices. The cars are fitted with lifeguards of the trigger pattern. Each car is wired for 15 incandescent lamps, which are run in series of five

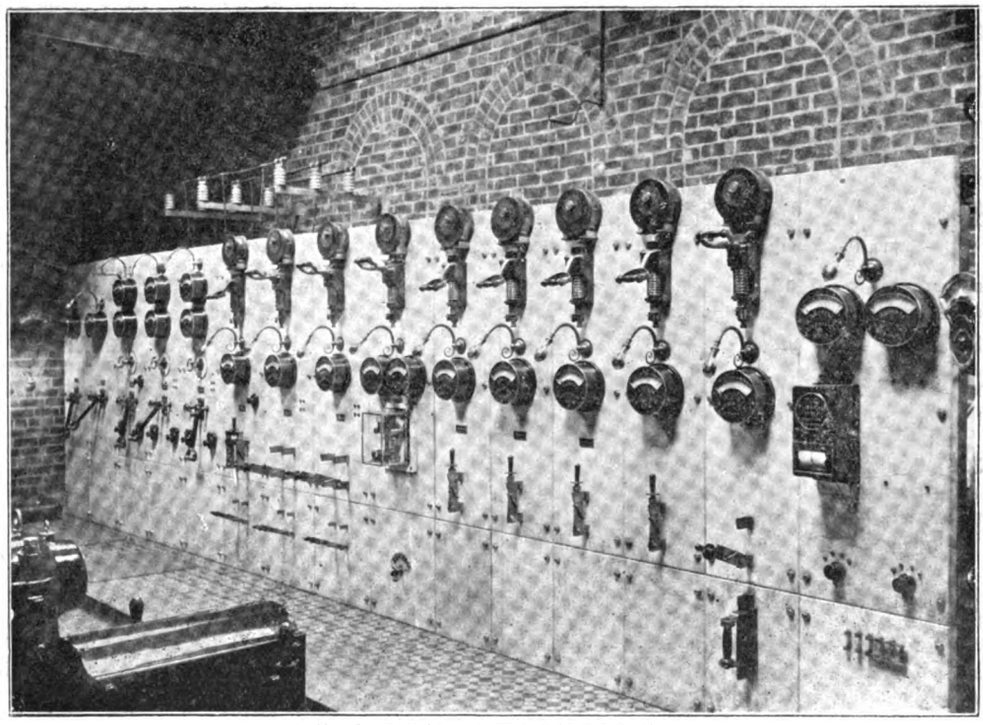

Fig. 9.—Switchboard. Wakefield Sub-Station.

over the motors to afford convenient access to the armature brushes, and to all bearings requiring frequent inspection and oiling. The platforms are carried on four steel angles, the bearers being extended without interfering with the clearance of the trucks. The main floor is laid with ⅞in. tongued and grooved boards 4in. wide with strips of deal 2in. off the main circuit, the wires being run inside the walls of the car behind the ventilators, thus being efficiently protected and put completely out of sight and reach. Two 16-c.p. lamps are fitted as head lights with reflectors. The cars are mounted on Brill trucks of the 21-E type, suitably built to support the car bodies and to receive the motors

Digitized by Google

and gearing. The axles are 3¾in. in diameter, and are made of Siemens-Martin steel capable of standing a tensile strain of 60,000lb. The wheels are of chilled iron and are 30in. in diameter. Each car is fitted with a complete Dick-Kerr standard equipment, consisting of two of Dick-Kerr's standard 25-A traction motors. The controllers are of Dick-Kerr's standard D.B I. form, C type, with metallic shield blow-out. Each consists of a strong cast-iron frame supporting two vertical cylinders, upon which are mounted the contact segments. One of these cylinders controls the power and speed of the car, and the other is for reversing the direction of motion. Means are provided in the controller for allowing either motor being entirely cut out of service, and the car driven by the other. The controllers are especially arranged with resistances for emergency braking, operated by the driving handle, which may be utilised either when the car is proceeding forwards or backwards.

The power station is situated at Belle Isle, Wakefield. The steam plant consists of four Lancashire boilers, with the usual accessories, including "Lord" furnaces, hand-fed mechanical stokers, a Green's fuel economiser, a water-storage tank with a capacity of 20,000 gallons of water, and two feed pumps capable of delivering 24,000lb. of water per hour against a pressure of 150lb. The feed water is drawn from the River Calder and town supply, the water for condensing purposes being wholly taken from the River Calder.

In the engine-room (Fig. 6) there are at present installed three "Howden" high-speed triple-expansion condensing engines, working at a steam pressure of 150lb. These engines run at 375 revolutions per minute, and are coupled to high-tension alternators of Messrs. Dick-Kerr's standard type, which generate three-phase current at 6,300 volts, 25 cycles, each set being provided with a direct-driven exciter. The alternators are "star" connected, have an output of 400 kw. continuously, and are designed to give an overload of 25 per cent. for one hour with a moderate rise of temperature. All three machines are designed to run in parallel with each other, means being provided for raising their voltage up to 6,600 to compensate for loss in the mains when running at a constant speed. The rotor spider is made of high quality cast iron, and is of a very strong design, the hub being provided with a flange for bolting to the engine flywheel.

The pole-pieces are made of laminated steel, and are held together between two cast-steel end plates of strong construction. The upper part is of a T-shape construction for holding the field coils in position, while the lower part of the pole-pieces is dovetailed for fixing on the rim of the rotor, and held in position by means of keys. The removal of the field coils is effected by sliding the pole-pieces from the dovetailed groove parallel to the shaft without disturbing any other part of the machine. The design and shape of the pole-pieces gives a distribution of lines of force in the air-gap to produce an approximately sinusoidal-shaped wave of E.M.F. The exciter is mounted on the extension of the alternator shaft. The stator frame is built in two halves, securely bolted together by means of finished bolts. The frame is made of cast iron, and is designed to allow complete ventilation of the laminations and at the same time to secure rigidity of the frame.

The coils are former-wound, and are embedded in rectangular slots, being held in position by wooden wedges, and are easily and quickly replaced. They are protected outside the laminations by means of a cast-iron shield, cast in sections, bolted to the frame and easily removable. This shield is of a perforated design, and does not in any way interfere with the ventilation. The main switchboard (Fig. 7) was built by Dick, Kerr, and Co., and consists of seven enamelled slate panels, each supported independently on an iron frame. The board consists of three generator panels, one power panel, and three high-tension feeder panels. Fig. 8 is a diagram of the connections to this board.

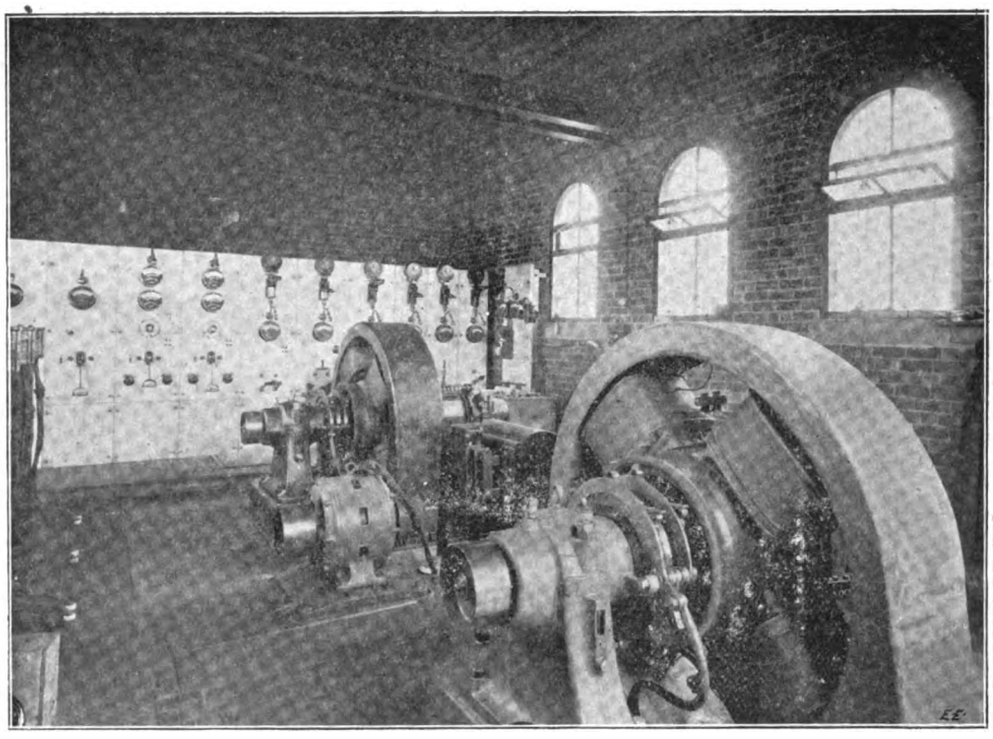

FIG. 10.—Rotary Converters, Rothwell Sub-Station, Leeds, Wakefield, and West Riding Tramways.

The sub-stations are fed from the main station by duplicate three-core, high-tension, lead-covered cables. At the Wakefield sub-station there are three standard Dick-Kerr 200-kw. compound-wound rotary converters, running at 750 revolutions per minute, and generating direct current at 500/550 volts. Each rotary has its complement of single-phase, oil-cooled, step-down transformers. The rotaries are capable of dealing with an overload of 25 per cent. for one hour. The switchboard in this sub-station is shown in Fig. 9. The Rothwell sub-station (Fig. 10) is similar to the one at Wakefield, except that its equipment comprises only two rotaries, with the necessary transformers and switchgear.

We are indebted to Messrs. Dick, Kerr, and Co. for the above description.

ELECTROLYTIC BLEACHING.

BY DR. ALFRED GRADENWITZ.

The use of chloride of lime in the bleaching industry, according to the practice of upwards of a century, is attended by many drawbacks. Apart from the instability

Digitized by Google

of this substance with regard to both air and light, and the extremely inconvenient preparation of the corresponding bleaching liquids, there will always remain on the fibres of the tissue a deposit of calcium carbonate, encrusting the latter, preventing a thorough bleaching, and, accordingly, resulting in the goods becoming yellow afterwards. As regards, on the other hand, such bleaching liquids as are obtained by electrolysis, experience has shown for a long time their use to be much more satisfactory than that of chloride of lime; special mention should be made in this connection of the apparatus designed by Mr. Haas and Dr. Oettel, which was one of the first allowing of the electric principle being employed on a commercial scale. We now learn that the inventors have just improved their apparatus considerably, and, therefore, wish to describe their bleaching device both in its original and new forms

The system of bipolar electrodes was chosen from the very beginning in the Haas and Oettel apparatus, this system affording the special advantage of reducing to only two the number of contacts to be superintended. The electrodes are made up of a carbonaceous matter, the terminal electrode being formed of two vertical plates, whereas the intermediate electrodes are transverse plates about 1cm. in thickness, which are inserted into the vertical slots of the apparatus. The sets of intermediate

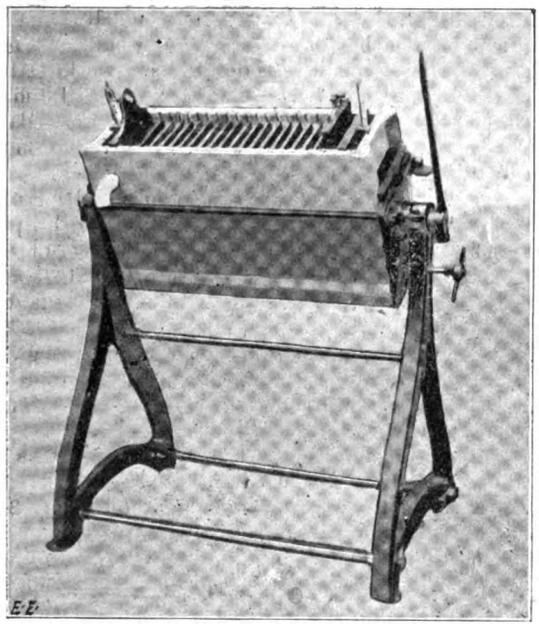

FIG. 1.

electrodes, so far from filling up the whole height of the apparatus, are each placed on an insulating bar, being prolonged by a similar bar beyond the level of the liquid. This arrangement is intended for forming at the bottom of each chamber a compartment where impurities may accumulate for a time without endangering the electrolyser, and, on the other hand, for maintaining the electrode entirely below the level of the liquid, so that any chlorine bubbles, even those evolved on the upper portion of the electrode, are absorbed by the liquid, thus avoiding any disagreeable smell of chlorine in the operation. The sodium chloride solution used as electrolyte enters the first chamber in a concentration of 6·4deg. Baumé, traversing all the chambers in a vertical serpentine path and entering the same alternately beneath and above a partition wall. From the last chamber it is discharged as bleaching liquid into a reservoir, where any smaller impurities due to the salt are deposited. Both at the entrance and issue there are thermometers allowing of the percentage of bleaching liquid being ascertained. On traversing the apparatus, the liquid, in fact, in addition to being chemically altered, becomes heated, experiment having shown a given increase in temperature to correspond with a given percentage in hypochlorite, taken by the salt solution on its passage, the difference of both thermometer readings thus affording a means of regulating and adjusting the speed of the liquid.

The apparatus, as shown in Fig. 1, is free to move in an iron frame, so as to allow of its being readily cleaned by turning the apparatus upwards at 90deg. Should any electrodes be damaged, only the electrode wall concerned will have to be taken off the apparatus, which, after inserting the new electrodes, will be ready for use again. On account, however, of the considerable life of the specially prepared electrodes, this is of no frequent occurrence, involving no disturbance in the service or any additional expense worth speaking of. The apparatus is designed for various current intensities and voltages, mostly for 65, 110, 120, 220, and 240 volts, as they are frequently connected to existing lighting systems. Now, whereas some 15 years ago, with the first type of apparatus, rather diluted liquids

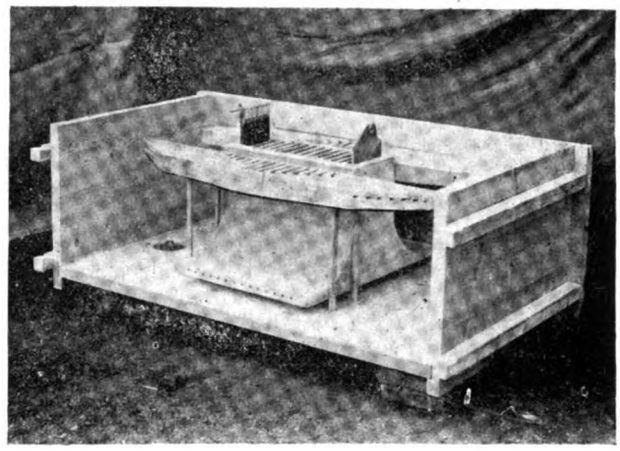

FIG. 2.

were required, it has of late years become necessary to increase the percentage in chlorine up to 5, 8, and even 10 grammes, in order to bleach goods that are less easily handled than cotton. It proving not convenient to make the liquid traverse the tank at a slower rate, on account of the inactive chlorate which is then formed, owing to the greater heating effect, means had to be provided for preventing any increase in temperature beyond a certain useful limit.

This result is obtained in the new type of electrolyser just brought out by Messrs. Haas and Dr. Oettel, Aue

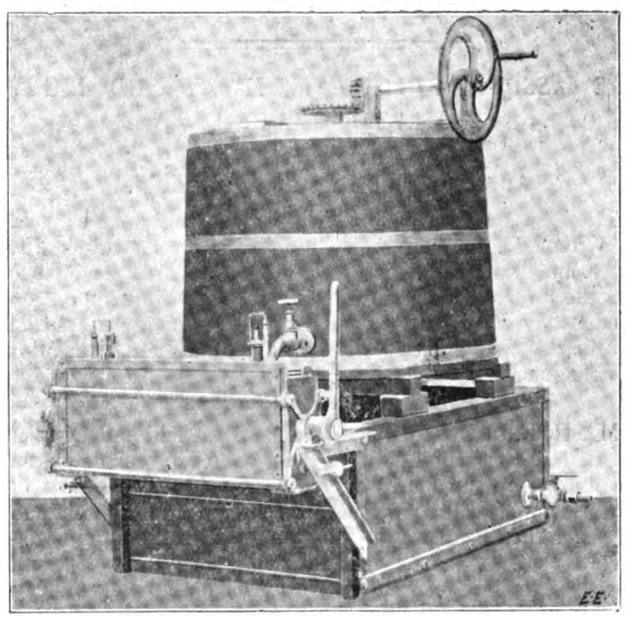

FIG. 3.

(Saxony). In order to convey to the apparatus a continuous supply of cooled liquid without the aid of any external mechanical force, the hydrogen evolved by electrolysis is used to convey the permanently cooled liquid through the electrolyser quite automatically without any regulation, superintendence, or additional outlay being necessary. This new electrolyser for concentrated liquid is shown in Fig. 2, the underlying principle being as follows: The

Digitized by Google

electrolyser proper has the shape of a case with a similar arrangement of the electrodes to the original apparatus but for its being entirely fitted into the bleaching liquid reservoir. The various compartments, being locked from each other, are fitted at the bottom with an opening through which the contents of each compartment communicate with the charge of the external reservoir. In the neighbourhood of the upper edge each chamber is in addition provided with an overflow tube penetrating also into the liquid reservoir. The latter is filled with salt solution until this reaches the overflow both inside and outside of the electrolyser. Now, if the current be completed, the liquid in the chambers will rise, forming a violent foam, while overflowing regularly through the tube and sucking fresh amounts of liquid through the opening in the bottom. The reservoir and chambers form a system of communicating vessels, a solid column of liquid being formed in the former, while the latter contains a mixture of liquid and hydrogen bubbles. As this mixture obviously is lighter, a higher column would be needed to obtain the equilibrium in the chambers but for the overflow. As long as there is an evolution of hydrogen, there will therefore never be a hydrostatic equilibrium, the liquid being drawn most rapidly through the chambers of the electrolyser. The fine bubbles of hydrogen carried along will allow of the lively movement and intermixing occurring in the liquid of the reservoir being readily noted over great distances, the more so as this intermixing is aided by the great distance between the inlet and outlet of the liquid. There are actually but very small differences in the percentage in chlorine throughout the operation in the different parts of the reservoir, this evidencing the high efficiency of the apparatus. The reservoir contains, in addition, a cooling coil, maintaining the temperature of the liquid below 24deg. C. As the cooling water remains perfectly clean and available for any use, the additional cost of this cooling device is confined to the first cost of the lead coil.

These electrolysers may readily be adapted to any requirements as regards both the consumption of salt and energy. In countries where salt is expensive, a most perfect utilisation of the salt is secured by the construction of the apparatus, whereas in the case of the salt being cheap the consumption of energy is reduced. In both cases the output of the apparatus may be so regulated as to obtain chlorine at an economical price.

THE ASSOCIATION OF TRAMWAY AND LIGHT RAILWAY OFFICIALS.

Autumn Meeting at Wakefield.

The autumn meeting of the above association was held in Wakefield on Wednesday and Thursday last week. It was a most successful gathering, both as regards attendance and the interest of the proceedings. The members met on Wednesday afternoon at the town hall, and were assured of a hearty welcome to Wakefield by the Mayor, Councillor E. Stonehouse.

Presidential Address.

Mr. H. ENGLAND, manager of the Wakefield and District Light Railways, who is president for the year, then delivered his address, in the course of which he said: The object of the association was to promote discussion and interchange ideas for the advantage of those engaged in the administration of tramways and light railways. As an association, they were not concerned with questions of policy. They did not discuss whether a corporation or a company was best fitted to control a tramway undertaking, but confined themselves to the discussion of practical everyday questions affecting the working of their undertakings. They had as members of the association managers and engineers engaged in operating tramways worked by companies, as well as managers and engineers in charge of corporation tramways. He would like to see all men engaged in tramway work brought together under the auspices of one representative association. The multiplication of associations having similar aims was to be deprecated. Many of the corporation tramway officials had, at one time or another, acted in a similar capacity for a company, and a number of company managers and engineers had been attached to corporations. Transfers were constantly taking place. The sole object of their existence as an association was to bring together men who had similar daily work to do, and who, by comparing notes and discussing freely the problems which they encountered, fitted not only themselves but their fellows for performing the work before them. It mattered not whether the work was done for a corporation or a company. The difficulties in working a tramways system were identical in both cases.

Prominent among the several important matters which would have to be dealt with in the near future was the carriage of goods on their tramways. This was not a new proposal, and it seemed surprising that more had not been done in the matter. If it were true that not more than two or three tramways were now carrying goods, there must be some reason for the reluctance of managers to cater for the traffic. Difficulties were made to be overcome, but it seemed to him there were some very real difficulties in connection with this question. In large cities passenger traffic was so heavy and continuous that goods traffic would have to be dealt with between 12 midnight and 6 o'clock in the morning, and as that would mean keeping the overhead line "alive" from Sunday morning to Saturday night, the time for repairs would be almost nil. Again, it must not be forgotten that it would not pay a system to run power plant outside ordinary working hours unless a decent load could be obtained. The real difficulty in arranging for goods traffic was siding accommodation. Unless they provided sidings they must interfere with their passenger traffic.

He was glad to find so many corporations and companies were beginning to see it was the convenience of the public that must first be considered, and to that end were making arrangements for through running. The difficulties anticipated were theoretical, and disappeared as soon as practical work commenced. His company had made an agreement with the Leeds Corporation, by which they were granted the privilege of running to the centre of Leeds from their terminus at Thwaite Gate, and the Leeds Corporation had equal facilities over the company's system.

It was a matter for regret that tramways were constructed of various gauges. Often in the same district the gauge of various tramways ranged from 3ft. 6in. to 4ft. 8½in., which made through running either for passengers or goods out of the question. There were very few places in this country where the standard gauge could not be adopted, and the Board of Trade would be doing a real service to the industry were they to insist on the 4ft. 8½in. gauge being used for all new work. Five years ago there was a golden opportunity to secure uniformity, but, unfortunately, the chance had not been seized, and the consequence was they saw towns like Bradford and Leeds, Bradford and Halifax, ready and willing, he believed, to exchange traffic, but unable to do so by reason of each system being constructed to a different gauge.

They were indebted to the Municipal Association for the splendid work done in reducing chaos to order in connection with tramway accounts. He was not one of those who attached much importance to comparisons, either of working costs or capital charges, but it was very convenient to know exactly where to look in an account for any item in which they were interested. They all knew that by increasing the mileage of their cars they could materially reduce the costs per car mile. Whether 1,000 or 10,000 miles were run, their general expenses were almost the same. They could increase their mileage to such an extent that although they succeeded in getting the lowest working costs in the country, their system would be run at a loss. He would recommend them to pay less attention to their mileage costs, but keep their attention on the percentage of expenses to receipts.

There were many subjects which lent themselves to discussion, and he would suggest a paper on roof-covered cars as likely to prove instructive and welcome to the members of their association. In his opinion, defects would manifest themselves where cars of the ordinary type had been fitted

Digitized by Google

with roof covers. The car framing required strengthening, not so much to carry the extra weight, but to withstand the strains set up by wind pressure. Stronger truck springs should be employed, and cantilever extension brackets fitted to overcome the oscillation likely to be set up by the top hamper. "Truck Design" would make a splendid paper, and he hoped one of their members would go thoroughly into the subject and give them the benefit of his investigation.

There was also room for great improvements in regard to telephones, and they should discuss the matter and attempt to find the best way of building a telephone line, the most suitable type of box, and the most reliable instrument.

Average Speed and Speed Allowances.

The next item on the programme was a paper by Mr. A. R. FEARNLEY, manager of the Sheffield tramways, entitled as above. In dealing with this important question, the author remarked that in order to obtain information he had sent out queries to all the British tramways, 81 of whom had replied. According to these replies, 14 miles an hour now appeared to be frequently granted, 10 tramways having stated that this was their maximum allowance. These towns were: Barrow-in-Furness, Birkenhead, Cardiff, Glasgow, Hull, Lanarkshire, Liverpool, Manchester, Walsall, and Newcastle-on-Tyne. Twelve miles an hour appeared to be the average maximum speed allowed, 37 tramways having obtained this allowance, amongst these being his own department—viz., Sheffield—also Salford, Blackburn, and the London County Council, in addition to many other important undertakings. There were 25 tramways allowed only 10 miles an hour as a maximum. He was at a loss to understand this in regard to such places as Chester, Blackpool, Doncaster, Farnworth, Southport (both company and municipal), and South Staffordshire, being quite certain there were many places on the lines named which might with perfect safety be allowed a much higher maximum than 10 miles an hour on certain portions of their route, and it probably only required application and a little pressure to obtain this increase. Eight miles an hour was the maximum on six tramways. There might be some particular reason for this low figure, which held in regard to the following towns—viz., Chatham, Dover, Oldham (Ashton and Hyde), Wigan, Wrexham, and Middleton.

Average Speeds.—Leaving out of the question light railway undertakings, he found some 14 tramways stated that they were obtaining an average speed of from 8 to 8¼ miles an hour. These were: Blackpool, Chester, Darwen, Doncaster, Gateshead, Gravesend, Grimsby, Lowestoft, Newport, Oldham (Ashton and Hyde), Poole, Warrington, Worcester, and another large undertaking. It was interesting to note that in this list there was not included a single tramway which had been granted the maximum allowance of 14 miles an hour, and, further, that only half of those named—*i.e.*, seven—had even 12 miles an hour allowed as a maximum, so that on many of these roads, where 8 to 8¼ miles was being obtained as an average speed, the maximum allowance was 10 miles an hour. Four towns returned 7¾ to 8 miles an hour as their average; 10 towns 7½ to 7¾ miles, among which were such busy tramways as Liverpool and Birmingham; 10 returned 7 to 7¼ miles, among which were Manchester and Glasgow; three returned 6¾ to 7 miles, included in the three being Newcastle and Hull; 12 returned 6½ to 6¾ miles, included in which were Huddersfield and Halifax (both towns with very steep gradients), and also Wolverhampton with a system of traction peculiar to itself; 10 returned 6¼ to 6½ miles; 10 returned 6 to 6¼ miles; three returned 5¾ to 6 miles (including Sheffield); two returned 5½ to 5¾ miles—viz., Norwich and Chatham; and two returned 5¼ to 5½ miles—viz, Ipswich and Wigan. Taking an average of the average speeds of the 81 tramways who had sent returns, he found this to be 7·24 miles an hour. There was no doubt that the average was considerably lowered in many towns by the great amount of time cars were allowed to stand idle at the termini. Whilst this standing over time had certain advantages, it would be found to pay very much better, he thought, to keep the cars moving and allowing them only just sufficient time at a terminus to reverse the trolley, motormen and conductor to change ends, etc., and then to be practically due away. The returns showed that very considerable advance had been made during the past three years regarding the question of speed allowed. Up to 1901 the majority of tramways were only allowed a speed of eight miles an hour. It was a very nice point at the present time to decide whether the speed on Continental tramways was in excess of the speed on British tramways, and if the roads which were described as "purely suburban" were left out of the question, the English tramways were at least equal to the Continental tramways, the average of the Continental tramways being returned at 7 2 miles an hour. The American return published in 1903 stated that their average speed on urban routes which pass through the centre of the city from one extremity to the opposite extremity was 8·13 miles an hour, and as many of our own routes complied with this condition, it would be seen that we were gradually approaching the American idea with electric traction.

Suggested Increase in Maximum Speed.—Was there any good reason why the same maximum speed which had been granted to motorcars should not also be granted to the tramways for those portions of their routes where it might be run with safety? The conditions which might be required were: an urban route; track to be kept in first-class condition, and to be either double track or long lengths of single track without crossings, etc.; cars to be fitted with power brakes to be used as service brakes, and gradients not to exceed 1 in 20. These conditions, he believed, were to be met with on many electric tramway systems at the present time, especially so on routes owned or worked by such companies as the British Electric Traction Company, and others with which members of the association were either connected or familiar. In America tramcars were now making through runs of over 90 miles, and attaining a maximum speed of 30 miles per hour. Unless higher speeds were allowed or maintained in this country, he failed to see how many of the existing and suggested suburban tramways and light railways were to be worked successfully. It was useless to expect that tramways working between towns 12 or 14 miles apart would attract much through traffic, if to complete such a short journey it took, say, 80 minutes. But if higher speeds were to be allowed and taken advantage of, some very decided change in his opinion would have to be made in our methods of constructing tramway tracks. To attempt to run at the speeds reported as being allowed and attained on American tramways, on tracks laid as at present in this country, on what might be termed the "solid system," would, he was convinced, soon lead to serious trouble, and he had wondered whether the advocates of goods traffic on tramways had considered the matter from this point of view. This question was one which should receive the attention of the promoters and officials of all tramways and light railways constructed for the purpose of linking up small towns, and which, consequently, ran through a good deal of sparsely populated country. It was, of course, a question which more closely interested those concerned with the management of tramway companies than the officials of municipal departments; but many of the latter were somewhat closely concerned in the question, and it would be of considerable assistance to have authority for the speeds which were now frequently attained, and which were certainly demanded by their customers.

DISCUSSION.

In the course of the discussion which followed, it was pointed out that the size of town had a great influence on the average speed obtained. No uniformity could be expected with regard to the maximum speeds allowed, since conditions varied, and what might be safely permitted in one place would be quite out of the question in another. The local authorities concerned, and not the Board of Trade, were to blame for many unnecessary restrictions as to speed. In order to maintain an average speed of eight miles an hour, it would be necessary to fix the maximum at 16 miles on any given system of tramways. That was to say, the average speed represented approximately half the maximum actually obtained. There was no doubt that the Board of Trade maximum allowances were still very much

Digitized by Google

below what could safely be permitted. With proper brake power a higher maximum than at present sanctioned would be quite safe in the majority of cases. And wherever increased speed had been obtained, the public had appreciated the change. Speed was the greatest factor in regard to the maintenance of track. With higher speeds tracks would certainly have to be laid differently. This question of track maintenance was a point which must be kept in view.

Tramway Car Wheels and Rails.

Then followed a paper by Mr. A. N. BANISTER, of Norwich, dealing with the cost and maintenance of tramway car wheels and rails, which questions, the author pointed out, were two of the most important in tramway management. The life of the wheels and also of the rails was very largely dependent on the condition in which the permanent way was maintained. The topographical conditions of the system were also important factors, and very frequently wheels which gave good results on one system would prove quite unsuitable for another. In order to arrive at a correct decision as to which was the best class of wheel to use on any particular system, it was essential that all the factors involved should have most careful consideration. Until comparatively recently the only possible wheel was of the chilled cast-iron type. During the last few years, however, they had been run very close, and in many cases surpassed by steel-tyred wheels, either with cast-steel or forged-iron centres. This result was due to the price at which steel-tyred wheels could now be produced, being about 25 per cent. less than it was five or six years ago, while the wearing qualities had been greatly improved.

With cast-iron wheels probably the most frequent cause of trouble was the chipping of flanges. This, on many systems, was unavoidable, for with the narrow-grooved rail required by the Board of Trade the flange of the wheel was of necessity so thin that the metal was chilled completely through the casting, and was consequently too brittle to long withstand the continued shocks received in passing over points and crossings. Flat spots constituted another trouble frequently experienced with chilled wheels, but could be almost entirely eliminated by careful training and discipline of the motormen. With steel tyres the flanges did not chip, flats were almost unknown, and the cars ran smoother and quieter, with, it was claimed by the makers, less wear on the rails. This latter point was, however, by no means established. On the other hand, trouble was often experienced through the flanges of steel tyres wearing completely off, in which case the cost of re-turning must be added to the price. There was also a reduction in life owing to the amount turned off to produce new flanges. Another disadvantage of steel wheels was their varying size through their lifetime, and consequent variation in the height of the car body from the rails, which introduced complications in the slipper brakes and life-guards, both of which had to be so arranged as to be adjustable to suit the varying height of the car. This variation amounted from 1¾in. to 2in. through the wear of the tyres.

The author then referred to the records of two experimental sets of steel-tyred wheels. These had cast-steel centres, and were bought on a basis of 1s. 8d. per 1,000 miles run in July, 1902. To this figure, the author continued, must be added the cost of

	s.	d.		£	s.	d.
Boring out and pressing on	11	0½				
Cutting off tyres when worn out	1	6	Per set of four.			
Taking out of car and replacing	11	2½		£1	3	9
Less scrap value, 3s. per set of four				0	3	0
Total per set				£1	0	9

The mileage obtained was 47,000. Hence cost per 1,000 miles per wheel for above work = 1s. 4d., making the total cost per wheel per 1,000 miles 21·4d. Cast-iron wheels at that date cost 30s., and ran 14,000. Allowing for value of scrap, this gave 24d. per 1,000 miles per wheel. Adding the cost of boring out, etc., 4d., this gave a total cost per 1,000 miles of 28d., as against 21·4d., showing a saving by the steel wheels per 1,000 miles of 6·6d. There remained the cast-steel centres, and allowing 10 per cent. per annum for depreciation, these were worth 32s. per wheel.

Proceeding to the question of the maintenance of wheels, the author said great care should be taken to have them pressed on to their axles to the same gauge. The practice in Norwich gave $\frac{1}{16}$in. clearance to each wheel. They should be pressed on at a steady pressure up to from 30 to 35 tons. The pressure should increase steadily from zero to the total amount—that is, each inch of travel should require an equal increase of pressure. If the pressure was unequal it indicated a bad fit, and there was danger of the wheel coming loose on the axle in service. They should also be carefully watched to prevent variation in size between the two wheels on one axle. At Norwich the wheels were calipered once a fortnight, and if the variation in diameter amounted to $\frac{1}{16}$in., the wheels were ground to size. At the same time the depth of the flanges was noted, and, if necessary, they were ground to the original depth. Flats were ground out immediately they were reported, the practice in Norwich being to punish any motorman who made two flats in six months for which he could give no satisfactory explanation; also if he neglected to report a flat as soon as it was made. By this means they had reduced their trouble from two or three flats a week to about one a month or less. To ensure wheels having equal wear, cars should be occasionally turned. The setting of the wheel brakes and the action of the brake gear should be carefully attended to. They had recently altered the pattern of their brake blocks in Norwich, so as to do away with the lip on the flange side, whereby the weight and consequent cost of the brake blocks was considerably reduced, and any danger of wear on the flange of the wheels removed, without, so far as he could see, any disadvantage. The average mileage of chilled wheels obtained on the Norwich tramways from the date of opening (July 30, 1900) had increased from 14,000 to 19,000. This improved result he attributed entirely to extra care and attention to the wheels and rails.

Continuing, the author pointed out, in connection with the maintenance and care of track, that one of the most frequent causes of broken flanges and excessive wear of rails was incorrect gauging of the track. Too much care, he said, could not be taken to ensure accuracy in this respect. There appeared to be a great difference in the practice of engineers in gauging the rails on curves. This was somewhat surprising, inasmuch as it was quite a simple matter to ascertain with great exactitude the correct gauge for any given curve. The same alteration of gauge was not, however, applicable to curves of all radii, but must be worked out for each different radius and gauge. With the aid of diagrams the author then described one method of ascertaining the amount of this gauge alteration. Referring to corrugating, he remarked that where this occurred steps should be at once taken to grind the head of the rail so as to prevent worse trouble. The method employed in Norwich was to fix a slipper formed of carborundum blocks to the slipper brake gear, and run the car up and down over the rail to be ground, a spring being inserted in the brake rod to give the necessary pressure.

DISCUSSION.

The discussion which ensued centred chiefly round the respective merits of steel-tyred and chilled wheels. Generally speaking, the evidence was all in favour of the former type. One speaker had obtained an average mileage of 56,297 with steel-tyred wheels for 20 cars so fitted. The cost worked out at ·0293d. per car mile, that of chilled wheels being about six times greater. Another obtained a mileage of approximately 5,000 for $\frac{1}{8}$in. wear of the steel tyres. With regard to the corrugation of rails, although it was agreed that this was a very serious matter, no satisfactory explanation was forthcoming as to its cause. The phenomenon might be associated in some degree, it was suggested, with high speeds, but no data were offered to prove or disprove this theory.

Radial trucks were incidentally mentioned and favourably commented on by several speakers.

Dinner.

After the first day's business the members and guests of the association were entertained by the directors of the Wakefield and District Light Railway Company at dinner.

Digitized by Google

Mr. Leon, chairman of the company, presided, and those present had a most enjoyable time.

Is Our Present System of Ticket Check the Best.

The first business on the second day of the meeting was the reading of a paper, entitled as above, by Mr. F. Coutts, Ayr, who explained that his intention was simply to introduce this important subject, and throw out a few suggestions, with a view to drawing out in discussion the various methods that might present themselves to the members. He thought everyone who had given the matter any thought would at once agree that to attempt to catch the dishonest conductor with a uniformed inspector was useless. The author went on to describe a few of the tricks resorted to by dishonest conductors. These tricks, and a dozen others well known to all tramway managers, could, he thought, be far more easily detected by someone travelling in plain clothes, paying his fare in the ordinary way, and whose connection with the tramway department was unknown to the men. But the question was: Who could be got for this kind of work, and when got, how long would they travel without being spotted by the men? In the case of large systems there was not so much difficulty as with small ones.

There were always to be found a number of suitable men, or, better still, women, who, for an annual payment of £10 or so, would be willing to give their assistance. In this way five to seven could be had for the wages of one inspector at present employed. A choice might be made of those whose employment compelled them to travel frequently. They would never have to enter the tramway office, but could do everything by correspondence. Insurance agents, collectors, sanitary inspectors, etc., would do well for the purpose.

An alternative system, and perhaps a better one, was the formation by all the municipal and company undertakings of a detective staff of specially trained men and women, whose duty it would be to travel here and there over the different systems, never remaining long in one town; and for a fixed annual sum, according to the size of the undertaking, each company or corporation would have one or more of the detective staff sent for a few days several times a year. The employés of such a department would be very valuable in hunting up special cases for managers who suspected irregularities. They could also keep an eye on motormen and conductors as to their general conduct, spot the careless motorman who helps to run up the big current bills, report on the careful one, take note of the impertinent conductor, and be able to give a favourable account of the cheerful, obliging, and civil conductor. He advocated the new system not with the idea that tramway men needed more supervision than other men, but with a view of saving the expense of a large staff of inspectors, and in order to get better reports than now seemed possible. At the same time the service of uniformed inspectors could not be entirely dispensed with, as they, too, had their uses.

Discussion.

A somewhat lengthy discussion followed, in the course of which it was agreed that the passengers rather than the conductors wanted watching—generally speaking, there was very little dishonesty practised among the latter. One speaker gave it as his opinion that checking by experts was very useful to managers. Uniformed inspectors were, however, too conspicuous for the work, and people picked up here and there would be no use whatever. Another speaker had absolutely no faith in private detectives, and suggested the systematic comparison of the men's average earnings as a possible way out of the difficulty. It was also suggested that pilfering among passengers in regard to excess fares could be best checked through the agency of police detectives by arrangement with the authorities.

Automatic Regenerative Control.

A reprint of an article dealing with the above subject was next taken. As this had been published some time ago it was not read. Mr. Raworth, jun., however, supplemented it by introducing his father's contribution to the discussion on Mr. John J. Hall's paper, dealt with in our issue for last week.

Several questions were afterwards put to Mr. Raworth, who, in reply, said that although with the system the motors were always in series, there was only half the usual pressure between the commutator bars, and this was better for them. With regard to sparking at the brushes, the motors used now had a fixed line of commutation, and, consequently, no sparking occurred so long as the field current did not fall below a certain limit. That a car equipped for regenerative control could not be reversed was claimed as an advantage. Shunt motors, as compared with series machines, were 8 per cent. heavier and larger for the same horse-power. A man of ordinary intelligence could drive shunt motors after a few hours' instruction. It was true that the system did not at present endow the cars with hill-climbing capacity equal to that obtained with series-parallel control, but series-parallel regenerative control was coming, and with that it was hoped to attain a speed of 10 miles an hour on up grades. The starting current was less than for series-parallel control.

Next Place of Meeting.

It was decided to hold the next meeting of the association at Bristol in April next year provided suitable arrangements can be made.

Visits.

The afternoon was occupied with visits. The first of these was to the Corporation electricity works, remarkable principally for the variety of alternators comprised in the equipment. A call was also made at the works of Messrs. E. Green and Son, of economiser fame, where splendid evidence was seen of this firm's world-wide reputation.

Next and last in order came the inspection of the Wakefield and District Light Railway Company's undertaking, a detailed description of which will be found elsewhere in this issue. A sub-station was visited, and tracks then made for the power station and car-sheds adjoining. The company have put up buildings of a very substantial character, but devoid of all architectural embellishment. An old chimney shaft has been utilised in the scheme, the flue from the boilers being brought round one end of the station to it. The engine-room walls, contrary to what is the usual practice now, are not fancifully tiled, nor is there provided an elaborate and expensive roof. At the same time the equipment is of the best that money could buy.

Mr. T. T. Davies, the resident engineer, can be trusted to get the best out of the plant. Results obtained after only three months' working augur well for the future. The cost of generation, including salaries, has been as low as ·39d. per unit delivered on the line, we understood, while Mr. Davies hopes to ultimately reduce this figure to ¼d. Certainly there is much to favour the attainment of this end. Coal delivered on the site is cheap—4s. 8d. per ton for pea nuts being the price at present ruling—while the station has an abundant supply of water available for condensing purposes. Jet condensers are used, without, it is interesting to note, air-pumps, and no doubt considerable economy is effected in this way.

After the inspection the formal opening of the works took place. It was explained that this ceremony could not be arranged for the time when the service of cars was inaugurated some three months ago.

OVERHEAD v. CONDUIT.

The following verbatim extract from the agenda of the London County Council is interesting reading. One could quote proverbs by the score, but the fact remains that the London County Council now desire to introduce themselves the trolley system, which they have so strongly opposed in the past. It is only justice that the metropolitan borough councils should now oppose this step, and that the London County Council should feel what its chief weapon against private enterprise—*i.e.*, arbitrary municipal opposition—is like.

4. In the London County Tramways (Electrical Power) Act, 1900, a provision (Section 23) was inserted which gave to each borough council absolute power of vetoing the

Digitized by Google

use of any overhead system of electrical traction in its own district.

We think that even the strongest advocates of the conduit system will agree that this is not a position in which the tramways authority should be placed. It is one thing to allow the local authorities every opportunity of criticising or opposing the proposals of the central authority; it is quite a different thing to give them an absolute veto which ties the hands of the tramways authority in the management of its business. Serious practical difficulties have arisen, as was to be expected. One effect of the position is that, even when the Council is able to agree with one borough council as to what should be done in its district, the Council is unable to proceed owing to the objection of another borough council. One borough council thus penalises another. We feel sure the Council will agree that it is desirable that it should secure freedom of action. The very important question as to the localities in which and the extent to which overhead traction should be employed, is a matter for subsequent decision by the Council. It is necessary to explain why we bring up this question at the present moment.

The Council on July 7 and 14, 1903, considered certain proposals which we submitted to it for the reconstruction, for electrical traction, of the Council's (northern) tramways. The scheme in question provided for the adoption on the lines of both the underground conduit and the overhead system of traction, and was the result of the most careful consideration by us of all the circumstances bearing upon the matter. The question of the system to be adopted depends to a great extent upon engineering conditions, and also upon the width of the thoroughfares traversed by the tramways, as the conduit system can only be satisfactorily used for double lines of tramways. Our proposals were based largely upon these considerations, and also had in view, as far as possible, the general policy of the Council of using an underground system in the central districts of London, reserving overhead traction for the more outlying districts. The Council adopted that portion of the scheme which related to the use of conduit traction, but before dealing with the proposals for overhead traction instructed us to ascertain the views thereon of the local authorities affected.

We accordingly at once placed ourselves in communication with the borough councils upon the subject, and on July 14 and Oct. 27, 1904, conferences were held between representatives of the borough councils and ourselves with reference to the steps to be taken in the matter. We placed all the facts bearing upon the question fully before the local authorities. Although certain of the borough councils have expressed their desire to assist the Council in the matter, the majority are not prepared to consent to the use of overhead traction. A copy of the notes of proceedings at the two conferences that were held has been sent to each member of the Council, from which may be gathered the attitude generally of the borough councils upon the subject. In these circumstances we have most anxiously considered what course we should recommend the Council to adopt. As the result of an exhaustive review of all the facts, we have decided to recommend that powers should be sought in the session of 1905 to secure the removal of the veto of the road authorities upon the use of overhead traction.

The final conference with the local authorities on the subject, which has emphasised the necessity for dealing with the matter on the lines we propose, has been held so recently that it was not possible for us, as we should have liked to have done, to have communicated to them our decision before submitting a report to the Council.

In addition to the Council's (northern) tramways, there are other tramway systems, either acquired or hereafter to be acquired, upon which, owing to engineering difficulties or the narrowness of the thoroughfares affected, it may be necessary to use overhead traction if the work of electrification is to be carried out expeditiously. Moreover, we think it right to point out that, as the result of the present state of affairs, a large number of thickly populated districts in which tramway development is urgently required will be seriously prejudiced owing to other authorities being unwilling to agree to the use of overhead traction in their boroughs

We quite recognise that there are many points—for instance, the system of paving and the method of carrying out the work—in regard to which the local authorities are necessarily closely interested, and the Electric Power Act gives them full rights in these respects. As already stated, however, we feel very strongly that the Council, as the tramways authority for London, should, in order that it may deal with the question of locomotion comprehensively both as regards traffic requirements and engineering and financial considerations, have a predominant voice as to the systems of traction to be used. We would point out, in this connection, that the consent of the Board of Trade is required by the Act to whatever system may be adopted, and the road authorities are entitled to be heard by the Board before such consent is given. Outside this very important reservation, we consider that the Council should be free to act if it is properly and satisfactorily to carry out its duties as the tramways authority, and to study from every point of view the interests of the public using the tramways. In dealing with the question of traction, it is to be borne in mind that the Council's policy is circumscribed by a variety of considerations which do not naturally weigh so strongly with the local authorities, who have principally in mind the local conditions obtaining in particular districts. The construction of new lines, the development of sparsely-populated districts, the framing of satisfactory and uniform conditions of labour, the linking-up of distinct systems of tramways inside and outside the county, are among the questions which are closely affected by the Council's freedom in regard to the systems of traction to be used, and we think that this freedom may properly be asked for without endangering the interests of the several road authorities concerned.

It should further be pointed out that in regard to these matters, and also as regards engineering considerations, the conditions which obtained in the case of the southern lines, which have been reconstructed for underground conduit traction, differed in important respects from the lines upon which, we think, it may be desirable to introduce overhead traction.

It is important that the matter should be dealt with without delay, particularly in view of the fact that the Council's generating station at Greenwich will be ready, it is hoped, early in 1906, and from this station power will be available for working a large portion of the tramways both north and south of the Thames. In the circumstances, we have decided to recommend that powers should be sought in the next session of Parliament. The solicitor has advised, in accordance with Standing Order No. 365, that the Council has power to promote legislation with this object. As required by Standing Order No. 363, we have informed the Parliamentary Committee of our proposal to submit a report to the Council in this sense.

The urgency of the matter clearly brings the case within the class contemplated by Standing Order No. 364; the terms of Standing Order No. 363, however, make a suspension of that order necessary:

(*a*) That the operation of Standing Order No. 363 relating to the time for the submission to the Council of schemes involving application to Parliament be suspended, in order that the following recommendation may be considered:

(*b*) That parliamentary powers be sought in the session of 1905 to relieve the Council of the obligation laid upon it by Section 23 of the London County Tramways (Electrical Power) Act, 1900, of obtaining the consent of the several road authorities concerned to the use of an overhead system of electrical traction.

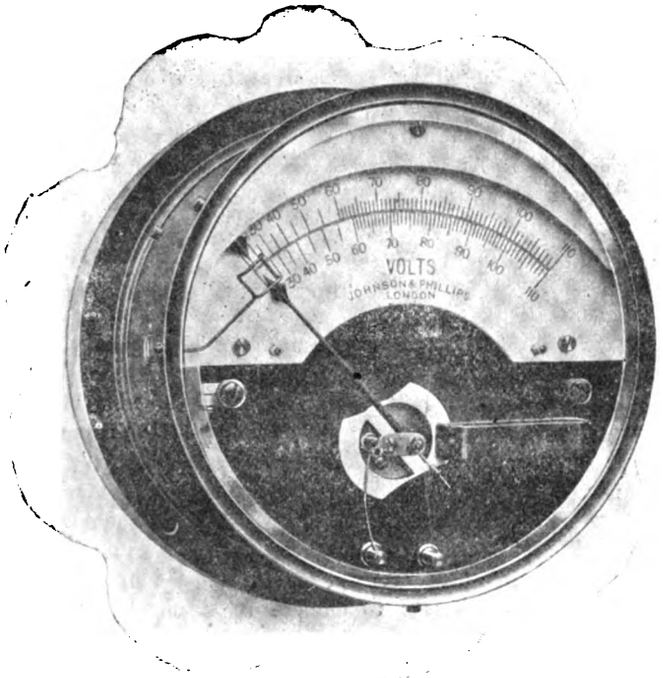
TRADE NOTICES AND NOVELTIES.

Differential Hot-Wire Voltmeter.

Messrs. Johnson and Phillips call our attention to their differential hot-wire voltmeter, which is illustrated herewith. This instrument is equally useful on continuous as well as alternating current circuits of any periodicity. It is fitted with two independent movements, one above the other in one case, and

Digitized by Google

with two scales on one dial. It is a great advantage to have the pointers opposite each other and so close together, while it is often a benefit that the instrument only occupies the same space as a single voltmeter. These instruments have been supplied to many central stations, and are chiefly used for paralleling alternators. The fact that the two readings can be seen at a glance on the same dial is a great advantage for such

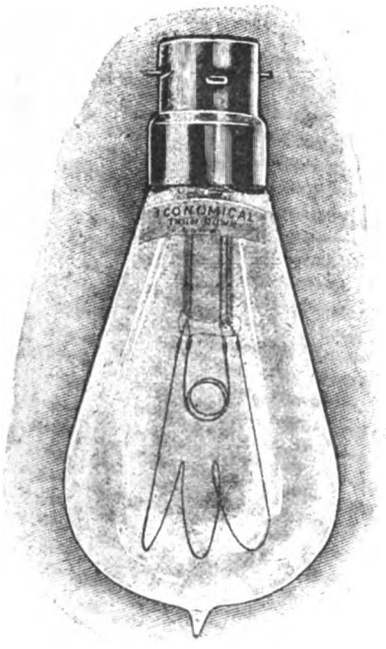


Differential Hot-Wire Voltmeter.

paralleling work, and it renders the observation of a difference between the voltage of the two machines very easy.

The Economical Turn-Down Lamp.

We illustrate herewith a type of lamp introduced into this country from America by Messrs. Geipel and Lange, Vulcan Works, St. Thomas-street, S.E. This lamp has two filaments—one the ordinary, the other a 1-c.p. filament. A switch is contained in the lamp cap for switching one or the other filament



Turn-Down Lamp.

into circuit. This can be actuated either by means of a pull-string or otherwise. The lamp is recommended for use in places where lights may be turned down with advantage, as in the case of gas-burners.

For the Drawing Office.

The accompanying illustration shows a very useful form of flexible curve made by Mr. W. J. Brooks, 33, Fitzroy-street, W. It consists of a flexible strip of celluloid or steel, provided with tabs at intervals along its whole length. Up to the 8in. size the curve can be held down in position by placing the fingers of one hand on the tabs, while the pen is used with

Brook's "Pattern A" Flexible Curve.

the other. In the larger sizes the tabs are secured by weights or drawing pins.

FORTHCOMING EVENTS.

FRIDAY, NOV. 11.

Electro-Harmonic Society.—At 8 p.m., concert (ladies' night).

Tramways and Light Railways Association.—Visit to London County Council's power station at Greenwich, etc.

Physical Society.—At 7.45 p.m., council meeting. At 8 p.m., "Investigation of the Variations of Magnetic Hysteresis with Frequency," by Prof. T. R. Lyle; "The Determination of the Mean Spherical Candle-Power of Incandescent and Arc Lamps," by Mr. G. B. Dyke; exhibition of physical apparatus by Mr. Robert Paul.

SATURDAY, NOV. 12.

Institution of Electrical Engineers (Manchester Students' Section).—Visit to Messrs. Mather and Platt's works.

Permanent-Way Institution.—At 3 p.m., council meeting at Nottingham.

Electrical Engineers' Corps.—Smoking concert.

MONDAY, NOV. 14.

Institution of Mechanical Engineers (Graduates' Association).—"New Electrical Swingbridge over Flood-Course of the River Weaver, Northwich," by Mr. T. P. B. Cliff.

TUESDAY, NOV. 15.

Institution of Civil Engineers.—At 8 p.m., further discussion on Mr. A. E. Carey's paper, "Coast Erosion," and Mr. E. R. Matthews's paper, "Erosion on the Holderness Coast of Yorkshire." Mr. J. F. C. Snell will read a paper on "Distribution of Electrical Energy."

WEDNESDAY, NOV. 16.

Society of Engineers.—Conversazione.

Society of Arts.—At 8 p.m., inaugural address by Sir Wm. Abney.

Chemical Society.—At 5.30 p.m., ordinary meeting.

Institution of Electrical Engineers (Students' Section).—At 7.30 p.m., opening address by Mr. J. Swinburne (past-president).

Royal Meteorological Society.—At 7.30 p.m., "Meteorological Observing in the Antarctic," by Lieutenant Charles Royds, R.N. (first lieutenant National Antarctic vessel, "Discovery"); "Decrease of Fog in London During Recent Years," by Mr. F. J. Brodie; and "A Hurricane in Fiji, Jan. 21-22, 1904," by Mr. R. L. Holmes.

THURSDAY, NOV. 17.

Institution of Electrical Engineers (Students' Section).—At 2.30 p.m., visit to the Great Eastern Railway Locomotive, Carriage, and Wagon Works, Stratford, E.

FRIDAY, NOV. 18.

Institution of Mechanical Engineers.—At 8 p.m., general meeting.

Junior Institution of Engineers.—At 8 p.m., Mr. W. H. Lindley will deliver his presidential address on "Municipal Engineering on the Continent."

December 1.—Annual dinner of the Institution of Electrical Engineers at the Hotel Cecil.

APPOINTMENTS VACANT.

Assistant Engineer, Croydon electricity works. Commencing salary, £2 per week. Applications by Nov. 12.

Assistant Electrical Engineer, Oldham Corporation. Salary, £275. Applications by Nov. 14.

Assistant Electrical Engineer, Kingston-upon-Hull electric tramways. Salary, £120 per annum. Applications by Nov. 14. See advertisement.

Station Superintendent, Chester Corporation, £130 per annum. Applications by Nov. 14.

Electrical Engineer, Battersea Borough Council, £400 per annum. Applications by Nov. 15.

Mains Superintendent, Poplar electricity works. Salary, £120 per annum. Applications by Nov. 18. See advertisement.

Mains Assistant, Blackburn electricity works. Commencing salary, £130 per annum. Applications by Nov. 18. See advertisement.

Junior Assistant for a firm of consulting engineers. See advertisement.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.

Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

TRAMWAY MATTERS—NATURAL AREAS.

The authorities at the London County Council are changing their minds, a process so far satisfactory in that we may hope to wake up some fine morning to hear of further changes. We are not going to dilate upon conduit or overhead systems to be used in tramway work, or to consider where the one or the other may be employed to advantage. The London County Council is growing in wisdom, and begins to see that what it has done is not what it should have done, and so is desirous of greater freedom, which in this case will probably bring less responsibility. At the present time each borough council has absolute power of vetoing the use of any overhead system of electrical traction in its own district. To us such a power is logical, is, in fact, the only course that could honestly be pursued. The citizens of a district elect their representatives for that district, who presumably carry out the wishes of their constituents, and say what the tune is to be that the piper has to pay for. If some other authority having other aims—it may be antagonistic to the district—is to come in, work its own sweet will without "by your leave," then local control becomes a myth, and trespasses upon the nonsensical. To a certain extent we are glad the matter has arrived at this stage, because for many years we have been advocating reform. The ancient haphazard divisions are not suited to modern requirements. Overlapping in all directions takes place, and conterminous authorities controlling various parts of the same natural area give rise to endless squabbles, from which no class except the legal benefits. Whether for intercommunication, lighting, water supply or distribution, sanitation, etc., the whole land can be more or less divided into natural areas, and these natural areas should determine the controlling authority, not the old, outworn, artificial areas, which have had their day, done their work, and ought now to rest in an archæological museum. We have mentioned the powers of the various boroughs, but the fun comes in when it is recognised that the County Council has powers to construct tramways in most of these boroughs, and by its own action in the past has debarred itself from that construction its responsible officials deem most advisable. Surely it has been hoist with its own petard. No matter what the decision of conduit *versus* overhead, it is absolutely certain that no work can be properly undertaken which has to be carried out so as to comply with the often conflicting views of various independent authorities. All works carried out under such a system are of the nature of compromise all round, so that in hardly a single direction is a detail carried out according to the real views of the expert adviser. The County Council now seeks powers "to relieve the Council of the obligation laid upon it by Section 23 of the London County Tramways (Electrical Power) Act, 1900, of obtaining the consent of the several road authorities to the use of an overhead system of electrical traction." We fail to perceive how the Legislature can relieve the Council, unless it nullifies municipal control altogether. In municipal work wisdom does not come unless you wait, and then experience often modifies to the direct contrary the views hurriedly come to by irresponsible and inexpert members of councils. The present action of the London County Council will bring the whole question forcibly to the front, and people will see that piecemeal action is of little use. All over the kingdom local squabbles or local jealousies are causing trouble. Birmingham, Manchester, Liverpool, Newcastle, and Plymouth have had trouble, because conterminous authorities have objected to the carrying out of schemes as proposed which were designed to serve natural

Digitized by Google

areas. The trouble concerning tramways is the more curious since the London County Council has been the most strenuous opponent to ordinary commercial company work, and has obtained powers of an exceedingly onerous character, which place the Council in a position to render company work within the borders of its control almost impossible. We do not imagine there can be two opinions about the substitution of natural in lieu of artificial areas in such work as intercommunication, water supply, lighting, etc., but why the London County Council should be favoured more than Manchester, Liverpool, or any other great centre, we fail to see, and trust, if the Legislature touches the subject at all, it will deal with the matter comprehensively. With regard to the particular case that has given rise to these remarks, the London County Council has shown itself liable to make a blunder in one respect; may it not be making a still greater blunder in much, if not the whole, of its tramway policy.

WHY?

In our last week's issue we gave a list of tenders for some telephone work which had been received by the Guardians at Richmond. The tender accepted was nearly 10 per cent. higher than the lowest tender received. Our readers will be surprised to hear that—if our information be correct—this accepted tender is for foreign-made instruments, and the lowest tender is for English-made instruments, which are quite capable of doing the same work. The question therefore arises as to why the Board of Guardians at Richmond and their architect have taken the higher tender? There are several answers which can be given, but the most charitable seems to be that the Guardians are afraid that if they encourage English industry and local labour they will lose office, because the need for a workhouse equipped with telephones may cease. At a time when the London County Council and some of the large provincial corporations have begun to realise that it is false economy to send work out of the country in order to save a few pounds in prime cost, it is curious to find the Richmond Guardians taking a diametrically opposite view and paying more for the foreign article. Again we would ask both the Guardians and the architect, Why?

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE RICHMOND (SURREY) GUARDIANS AND GERMAN TELEPHONES.

SIR,—I observe from the Richmond papers of Saturday last that at the meeting of the Richmond Board of Guardians Colonel Henchy, who was in the chair, protested that the Board had adopted German telephones for the installation at the workhouse, notwithstanding that they might have had British manufactured instruments for £10 less money. This appears to open up a matter of special interest to ratepayers, whose money to the extent of £120 is being spent on the installation, and of general interest to the community at large as an example of the way in which public money is leaving the country.

I have made enquiries of the firm who sent in the lowest quotation for British telephones, an alternative one of £110. 16s. 5d., as against £122. 3s. 7d. for the German instruments specified by the Guardians. The proprietor of the business in question is a ratepayer in the borough, and, I am informed, signed his tenders as such. His alternative estimate clearly pointed out that the instruments were of the same British manufacture as some of those which are at present installed at the workhouse, although some there are German, but all are to be embodied with the new ones in one big system to work in connection with one another.

I questioned him on the subject of local labour, which I understood from the Guardians is to be our strong point in the future, and I thought I had him here—but no. It appears that by a strange coincidence he had made a provisional arrangement for by far the greatest portion of the work to be done by the very firm of Richmond builders whose estimate for the building of the new Board-room and offices, although not the lowest, was subsequently accepted for this very reason. Now, Sir, may I ask why the Guardians, in view of the distress and want of work among our own artisan classes, should go out of their way to support those of other countries, and why we should be asked to pay more money for this installation than if the order had been confined to these shores?—Yours, etc.,

Nov. 9, 1904. PUZZLED.

BIRTHDAY HONOURS.

The list of honours conferred by his Majesty the King in commemoration of his birthday includes two names which are well known in the profession of electrical engineers. By the conference of a knighthood upon Dr. J. Wilson Swan, F.R.S., his Majesty has given pleasure to all electrical engineers. Electrical Engineers in 1900 conferred upon this distinguished pioneer the honorary membership of the Institution, but the kingly act which makes him Sir Joseph Wilson Swan is a wider recognition of his services to the nation. It is in connection with the invention of the incandescent electric lamp that the new knight is always associated, and we need hardly repeat here the story of this invention. Although after an expensive legal fight Mr. Edison's name became associated with Sir Joseph W. Swan's invention, we have always looked upon the work carried out at Newcastle as giving the essential discoveries which rendered incandescent lamps commercially possible. The discovery of the means of producing a squirted carbon filament of uniform density and section was the great step which rendered electric lighting possible for interior work. Quite apart, however, from this invention, Sir Joseph Swan's researches in other directions, and especially in photography, have been so successful as to warrant the honour now conferred upon him. Again, his last presidential address showed an insight into the practical details of electroplating and copper depositing, which could only be acquired after arduous and lengthy experiments. The selection of his name in the new list of knights will be everywhere appreciated, and we can only add our congratulations to the recipient of the honour.

The other name referred to above is that of the Hon. Charles A. Parsons, D.Sc., F.R.S, who has been made a Commander of the Most Honourable Order of the Bath. By this the King has recognised the importance of the steam-turbine, which owes its commercial possibilities entirely to the Hon. Parsons. We remember when in the early eighties the Parsons turbine was first being introduced in the Newcastle district by the then firm of Messrs. Clark, Chapman, and Parsons. After considerable success in shiplighting work, the turbines, direct coupled to dynamos, were extensively used for the lighting of the Newcastle Exhibition in 1887. They supplied the light to all the main buildings in the exhibition by means of the large Sunbeam incandescent lamps which the same firm were then manufacturing. The exhibition brought these high-speed turbines to the notice of the engineering world, and their history since then has been one of continued success. When the above-mentioned firm dissolved partnership the Hon. C. A. Parsons, C.B., started the firm which now bears his name, and designed an improved form of turbine which is now so largely used. The enormous contracts which are now being carried out with steam-turbines as the prime movers are evidence of the foresight and engineering skill of this inventor in recognising and overcoming the inherent difficulties of this great problem. The extension of the steam-turbine from its orignal purpose of driving dynamos to the direct propulsion of steamships is one which will be

followed with the keenest interest. Its success is assured, and was no doubt in the mind of the King when he selected his birthday list of new Commanders of the Bath. Here again we would add our congratulations to those which will be sent from all parts of the world to the Hon. Parsons, C.B.

RADCLIFFE ELECTRICITY WORKS.

One of the latest schemes which the Urban District Council of Radcliffe have had in hand and have brought to a successful completion is that of the electricity undertaking for the supply of electric energy for tramways and lighting in the district. Some time ago the Council wisely decided that a good electric lighting system would be essential, the population of the district being about 25,000, and a loan of £21,500 was obtained to be expended on the scheme. In 1902 specifications were prepared for the various sections of the scheme by Messrs Lacey, Sillar, and Leigh, the consulting engineers to the Council, and work was commenced about the end of the same year. The whole of the works have been successfully carried out by the various contractors under the direct supervision of the consulting engineers, whilst Mr. Henry, the resident engineer, has also given valuable assistance.

The Council are to supply current for about seven miles of tramway track, they having installed a traction switchboard at the station and having laid the permanent way and the necessary cables, etc. The tramways will be operated by the Bury Corporation, they providing the overhead equipment and the rolling-stock. The work in connection with the permanent way and the overhead equipment is at present in progress, and it is expected that the complete system of tramways will be in operation shortly. The works are conveniently situated in Lomax-street on the banks of the Irwell, the water for condensing purposes being obtained from the river. The plans of the buildings were supplied by Mr. Rothwell, the Council's surveyor, the work being carried out by Messrs. Sandyford and Thornley.

The buildings comprise boiler and engine room, accumulator room, testroom, offices, etc., adequate provision being made for extensions. The engine-room has a basement for the convenience of pipes and cables, the condenser pump, motor-generator, and balancer also being situated here. The steam-generating plant consists of two Lancashire boilers supplied by Edward Heaton and Sons. Each boiler is 30ft. long measured between the end plates, and 7ft. 6in. in diameter measured inside the inner rings of the plates. The grate area is 36 square feet, and the working pressure 160lb. per square inch. They are provided with the necessary safety high-steam and low-water valves and two accessible check feed valves. Two superheaters, supplied by the same firm, of Simpson and McPhail type, are erected at the back end of the boilers in the path of the boiler flues. Each superheater is fitted with a 2in. by-pass pipe and valve, and with a safety valve, thermometer, pockets, etc. The economiser, supplied by the same firm, of the Green type, is fixed in the main flue. It consists of 192 tubes, each tube being $4\frac{9}{16}$in. in diameter and 9ft. long, divided into two sections in rows of eight tubes wide, and fitted with deflectors at the back. The boiler feed pumps, supplied by Messrs. Mather and Platt, consist of one electrically-driven pump and one steam-driven pump, each being capable of delivering 1,800 gallons of water per hour against a steam pressure of 160lb. per square inch, the feed water being taken from a hot-well situated in the pump-house. The electrically-driven pump is three-throw single-acting, the stroke being variable. The steam-pump is of the simple direct-acting vertical type. The condenser, which is situated in the engine-room basement, and supplied by the same firm, is of jet type, with three-throw pumps electrically driven. The jet nozzles are of renewable type, and the condenser is of sufficient size to deal with 15,000lb. of steam per hour, and giving a vacuum of 26in. with cooling water at a temperature of 65deg. F. The cooling water is lifted approximately a height of 15ft. from the River Irwell, and the discharge is taken into the hot-well before mentioned, which overflows into the river. The various steam, exhaust, feed, and water pipe accessories were put in by John Wolstenholme and Son, an oil-filter being fixed in circuit with the main exhaust pipe and condenser.

The generating sets consist of two 120-kw. steam dynamos supplied by Messrs. Mather and Platt, with engines by Messrs. Browett-Lindley. The engines are of two-crank enclosed vertical compound type at a speed of about 500 revolutions per minute with a steam pressure of 140lb. per square inch, with a steam-chest, and working condensing with a vacuum of 24in. Each dynamo has a capacity of 120 kw., the current output being 250 amperes at 480 volts, the voltage being variable between 480 and 440 by means of a shunt resistance when running as a shunt machine. When running as a compound machine each dynamo has a constant potential of 550 volts maintained at any load between 70 and 220 amperes. The outputs given above of the steam sets are when working normally, but each set is capable of an overload of 25 per cent. for short periods. The dynamos are four-pole machines with bar-wound armatures. The balancer, supplied by Messrs. Crompton and Co., consists of two four-pole machines coupled together on one bed-plate, running at a speed of 800 revolutions per minute. The motor-generator, supplied by the same firm, consists of two 16-kw. dynamos and one motor, all mounted on one bed-plate, this set being used for battery-charging purposes when steam dynamos are running on traction. Both the lighting and traction switchboards were supplied by Messrs. Statter and Co. These boards consist of enamelled slate, upon which the various necessary instruments are mounted. The measuring instruments are of Crompton type, and the circuit breakers of B.T.H. type. The accumulators, supplied by the British Accumulator Company, consist of two sets of 123 cells and six spare cells, making in all 252. The battery is capable of giving a discharge of 40 amperes over a period of 10 hours and 180 amperes for a period of one hour, the voltage of each cell being not less than 1·8 at the end of discharge. The travelling crane, supplied by Messrs. J. Spencer and Co., is capable of lifting 10 tons. The station wiring for lighting and motors was carried out by Messrs. D. Firth and Sons, two switchboards being fixed in the engine-room, one for the control of the lighting and one for the control of the motors.

The lighting and traction cables, pilots, conduits, etc., were supplied and laid by the Callender's Cable and Construction Company, the work being supervised on their behalf by Mr. Mollard. For the lighting system the feeders terminate in two lighting pillars, from whence several distributors are taken. The distributors are lead-covered fibrous cable, laid in Howard troughing. The feeder cables and pilots for the tramways are in all cases lead-covered fibrous cables drawn into stoneware conduits. The rail bonds supplied by the Forest City Electric Company are of the protected type.

The supply of electricity for lighting and power purposes was commenced about the end of August, and already there are a good number of consumers connected or are about to be connected. The works were formally opened on Oct. 5 by Mr. J. H. Lund, chairman of the Electricity Committee, in the presence of a large assembly, when Mr. F. A. Cortez Leigh, on behalf of the consulting engineers, presented him with a gold key.

INSTITUTION OF ELECTRICAL ENGINEERS.

Inaugural Address.

BY ALEXANDER SIEMENS, PRESIDENT.

In taking the chair for the coming year, I am placed at a disadvantage compared with my predecessors, in so far as I cannot begin my address by thanking you for having elected me, but have to explain how it has come about that I occupy this honoured position. The late lamented death of our secretary induced the Council to consider how a continuous policy in the management of the affairs of the Institution could be best ensured; and as a result certain

Digitized by Google

alterations in the by-laws have been suggested by the Council, and have been sanctioned by you in due course. The revision was, however, not formally completed in time to propose a president-elect at our last annual general meeting, and the expedient was adopted of proposing Mr. Robert K. Gray for a second term of office, to which he agreed, on condition that he might resign in favour of a president-elect as soon as the alteration of the constitution had been duly carried out. As our new secretary had been only a short time in office, the Council decided to elect a past-president as the successor of Mr. Gray, and did me the honour to select me, when Mr. Gray formally intimated that he did not wish to serve a second time as president. During the recess Mr. Gray, with a numerous party, went to the United States, as you all know, and during his absence it has been my sad duty to represent you at the funeral of our hon. member and past-president, Major-General Webber, who has the further claim on the regard of the Institution, that he was the last surviving founder.

Members of Council know better than the other members of the Institution how indefatigable General Webber was in promoting the interests of the Institution in every possible way, not only by attending meetings of Council and of committee, but by suggesting improvements wherever he thought imperfections existed. He notably took an active part in all the negotiations connected with the acquisition of a site for an Institution building, about which the Council reported at the last meeting. In him we have lost a true friend of the Institution, and his memory will be held in honour as long as the early days of our Institution are remembered.

It would, perhaps, appear natural to take this opportunity of comparing the status of the Institution, or, rather, of the Society of Telegraph Engineers, at its inception with the position now occupied, but this has been done so recently in presidential addresses that my words would be only a superfluous addition to the remarks more ably expressed by my predecessors. On the other hand, the causes which influence the growth of industries, and thereby the rise of institutions connected with them, will bear further discussion, as they are of the most varied character, and are an apt illustration of the interdependence of all factors of modern civilisation. Considering the features of this civilisation generally, it will be acknowledged, after a short reflection, that its true foundation is the lowering of the cost of production—in other words, the progress of civilisation is in proportion to the cheapening of articles of consumption. Although this may sound purely materialistic, the process of lowering the cost of production, which implies the employment of all the knowledge we can acquire, and of all the training the best schools can give us, results in greater ease of acquiring the necessaries for keeping alive, and therefore it gives us more time to cultivate other aspects of our existence. This general principle has manifested itself as much in the electrical industry as elsewhere, and further progress appears to be dependent on further lowering of the cost of its products. When we come to enquire into the means for carrying out this principle we soon recognise that the solution of the problem depends upon a variety of circumstances which all influence the result, although they may be investigated and discussed separately.

For "internal working," if I may say so, every industry depends upon three principal factors: (1) the capital which provides the works and the raw material; (2) the workman who converts the raw material into the finished product; (3) the management. It is quite idle to try to establish the relative importance of these three factors, for each one is indispensable, and likewise the prosperity of each one is inseparable from the prosperity of the others; so that no industrial establishment can flourish where these three factors do not co-operate heartily and harmoniously. As a first condition for further progress we should, in fact, recognise the identity of interest between the capitalist, the workmen, and the management, as any measure which is intended to unduly favour any one of these three factors would inevitably increase the cost of the product beyond what it ought to be and thereby restrict its sale, thus damaging all three. When we examine in detail in what way each of the three factors can contribute to the lowering of the cost of production, we find ample confirmation of the intricacy of the problem.

Taking capital first, its share in the value of the finished article is proportionate to (*a*) the cost of the depreciation and maintenance of the works and of their outfit; (*b*) the cost of the raw materials; (*c*) the profit, representing interest on the total capital invested in the undertaking. In order to minimise the first item the works ought to be carefully planned and equipped, so as to be careful of turning out the maximum quantity of produce, and their machinery should be selected and laid out in such a way that its wear and tear is only due to its legitimate working, and that the handling of all materials is reduced to a minimum.

The second item, the cost of raw materials, is too intimately connected with fiscal questions for treatment in this address; but incidentally it should be noticed that practically there is no such thing as "raw material"—at least, the Royal Commission on Trade declared itself unable to define what is "raw material." It is true that each industry works up what it designates as "raw material," but this in turn is the finished product of some other industry; even the products of nature, whether minerals, plants, or animals, form the basis of great industries, and are more correctly called finished articles than raw materials. In any case for the natural progress of industries, the cost of the materials which they work up should be kept as low as possible, and every increase of it is a hindrance to their proper development.

There is, apparently, not much difficulty in diminishing the third item—the profit on the capital invested—but it stands to reason that the interest earned by the capital could not fall below a certain amount without the industry in question losing the support of capitalists and collapsing. The rate of interest may therefore be considered a fixed quantity, and in order to diminish the amount payable under this head, it is important to avoid burdening an undertaking with more capital than is required for setting it up as a going concern and for providing a reasonable amount of working capital. A particularly dangerous way of increasing capital expenditure is buying patents, as the best inventions may be superseded at any time either by better ones or by a change in trade requirements, for in such cases the capital invested in the patent would be quite unproductive, while the interest would still have to be paid. It is much more equitable to remunerate an inventor by a royalty, so that his reward may be in proportion to the success of his invention, and to charge the amount that may have to be expended in developing the invention to revenue account.

When considering the influence of the second factor—the workman—on the value of the product, it becomes clear very soon that the amount of work turned out in a given time has a twofold influence on the result, as the time occupied in producing an article not only regulates the amount of the wages, but also the proportion of the dead charges to be debited to the article. It is, therefore, quite certain that in order to contribute his share to the lowering of the cost of production of an article the workman has to turn out a greater number of these articles in a given time, and the problem is how to attain this object without endangering the interest of any one of the three principal factors. This sounds almost as if slave labour would prove an economic plan in the carrying on of industries: it can, however, hardly be contended that the interest of the workman is considered under such conditions, and for this reason alone it should be condemned, even if there were no other objections to it.

There are, however, legitimate ways in which the amount of wages to be charged against an article can be diminished. Most important among them is the substitution of machine work for hand labour, and where this is done, unskilled labour should be utilised for running the machines under the supervision of a few skilled artisans. Here, again, the interests of the workman appear to suffer, and whenever he is confronted with a new labour-saving machine he airs his old grievance that machines will deprive the workingman of his living, just in the same way as he opposed the use of all machinery a hundred years ago. The

Digitized by Google

lesson taught by experience has evidently not made an impression; but nobody can deny that, instead of making skilled labour superfluous, the introduction of machinery has resulted in more skilled workmen being employed, and at better wages than before, and similar developments are likely to follow when the workman is further relieved from hard toil by his best friend the labour-saving machine. Another feature of machine work is the greater accuracy that can be attained, so that, while the cost of production is lowered, the quality of the product is improved, and at the same time the interchangeability of parts is secured, which in itself contributes to the lowering of cost. It is not easy to convince workmen that "increase of output" is of advantage to them; if we are to accept statements published in the newspapers, they rather believe in the direct opposite, "restriction of output," although their official organs repudiate the idea.

This desire to do as little work as possible is, in a way, ingrained in us all, but in the workman it is in addition reminiscent of the mediæval guilds, those ideal trade unions which have been abolished everywhere as incompatible with modern industries. In their time they have filled a useful purpose, but the conditions which made them appropriate have entirely passed away, and any attempt to revive them or their principles is doomed to failure. According to their constitution nobody was allowed to exercise a trade, or even to sell its products, who had not been brought up to it in accordance with strict regulations, first serving an apprenticeship, then becoming a journeyman, and finally advancing to be a member of the guild if he could produce a satisfactory masterpiece. The number of apprentices taken on was prescribed and the number of masters in each community was limited, so that every craftsman was tolerably certain of constant employment.

No wonder that such a condition of things has a great attraction for the modern workman, especially when he happens to be out of work, and that he thinks he can improve the position of his class by restricting output and by insisting on a minimum rate of wages, after the manner of the old guilds. His reasoning, apparently, is that modern conditions of living require a number of things to be done every day; consequently, the less work each individual does the more individuals have to be employed, and if a minimum rate of wages is enforced, the question of the unemployed is satisfactorily solved.

In the Middle Ages, when each community was to a great extent self-contained, and the intercourse even between neighbouring towns was hampered by bad roads and insecure travelling, it was possible to adopt this solution of the problem, especially as the style of living was very much the same for the great majority of people, while their requirements did not include much beyond their bodily wants. During this time the workmen, when they had become full members of the guild, were practically chained to the soil, and in return for this immobility their number in a community was limited. They had to do all their travelling, if they were that way inclined, while they were journeymen, and most of them used that time for picking up information useful for their trade, even in foreign countries. As the facilities for travel increased, and with it the intercourse between distant countries, the prices of products fell which formerly had been obtainable only by the very rich, and gradually the great majority of people have become accustomed to surround their daily life with luxuries, meaning thereby everything that is not absolutely required to keep body and soul together. This alteration in the way of living has been further accentuated and extended by the substitution of machine work for manual labour; in fact, this change of the mode of production is still going on to the great advantage of the consumer. In other words, everybody is sharing in the benefit of the cost of production being lowered.

On the position of workmen the further circumstance has exercised an important influence that, by the facilities of intercourse and by the employment of machinery, huge factories are enabled to undersell works on a small scale, so that for successful competition in modern industries capital has become a necessary adjunct. It is, therefore, no longer possible to insist on masters being selected only from the class of workmen, nor is the work which is absolutely necessary for the daily existence of mankind sufficient to keep all workmen in constant employment, so that the old remedy of the guilds can no longer be applied. Restricting the output has, in fact, nowadays exactly the opposite effect to what it is intended for. When the price of an article is raised owing to this supposed remedy, a number of consumers begin to do without it, and the demand for it diminishes, so that less people can be employed on its production. Instead, therefore, of securing employment for more men, it will endanger the continuance of work for those who restrict output under the mistaken impression that they are benefiting their fellow-workers. How far this restriction of output is carried sometimes can be illustrated by the action of the workmen in shipyards and boiler shops, who either refuse to work pneumatic riveting machines or insist on doing no more work with the machines than could be done by hand, exacting the same prices per rivet as for hand labour. It escapes their attention that they handicap their employers in competition with others who are free to utilise such labour-saving devices to their full extent, and that unsuccessful tendering means no work at all.

On the other hand, a good example of the beneficial effect of lowering the cost of production is furnished by the trade in incandescent lamps. At first, when they were made by a few highly-skilled workmen and sold at 25s. each, there were very few consumers able to indulge in the luxury of electric light, and the number of hands employed was correspondingly small. That condition of things has been absolutely changed since the price has been lowered to its present level; thousands of skilled workers are employed in the production of lamps, in addition to the tens of thousands of unskilled people who attend the machinery used in the manufacture and perform the manifold functions connected with this trade. Such a result could not have been attained without the use of labour-saving machinery of the most varied description, and it seems incredible that, in spite of this and similar demonstration of the beneficial influence of increased output at lower cost, the workman should remain blindly hostile to this principle and cling to his exploded remedy of restriction of output. This attitude is illustrated by a remark which a leading workman made when the importance was impressed on him of diminishing the amount of wages chargeable to each individual article, because in this way the article became cheaper, more customers could be found to purchase it, and consequently more workmen would be required to produce it. His observation was that he fully understood the argument, and that it meant, in his opinion, when carried out to its full extent, that everybody would find employment if no wages were paid at all. It is rather sad to think that such a man, who has been elected by his fellow-workers to a high office in his trade union, should not be able to discriminate between the rate of wages paid to a workman and the proportion of such wages chargeable to each article produced by that workman.

Workmen have also a rooted objection to seeing machines worked by unskilled men, which is apparently based on the mistaken notion that such unskilled men are replacing skilled workers. They, however, overlook the fact that labour-saving machines are only introduced where the same articles produced by hand labour would be too expensive for sale; consequently, no skilled workmen could be employed instead of labour-saving machinery. Another fetish of the working-man is his desire that all workers should be treated alike, and no preference given, absolutely ignoring that the capable and industrious are more deserving than the lazy and careless workers. How disastrously this tendency sometimes operates I can tell from a personal experience when I started the first continuous working tank glass furnace in Leeds, about 25 years ago. Up to that time all glass for bottle-making was melted in pots, and the glass-blowers were never certain when their services would be required, as it was almost impossible to melt the batch in a given time. Again, their work was frequently interrupted if the furnace man was unable to control the heat properly, so that the melted glass was either too hot or too cold. In any case, the working out of the last portion was very troublesome,

Digitized by Google

as the pipes had to be dipped far into the furnace to reach the bottom of the pots. All these drawbacks are overcome in the tank furnace, where the melted glass is always ready for the blower; its temperature is under perfect control, and its level is always the most convenient for the workers.

As it happened, the secretary of the trade union worked at the furnace and expressed repeatedly his great satisfaction at this complete solution of all their difficulties. His union consented to the prices of bottles being lowered, but in spite of that the men succeeded in earning higher wages than before, owing to the greatly increased facilities of working. Encouraged by the success, the firm desired to establish three shifts of workers in order to utilise to the full the continuous working of their plant, but the trade union would not give their consent, alleging that the firm were making enough profit working two shifts. The firm then resolved to build some more furnaces of the same kind, but, to everybody's astonishment, the trade union threatened to withdraw all their members if another furnace were built. I asked the secretary for an explanation, and reminded him that he had nothing but praise for the improved system of glass-melting. In reply he said that he had nothing to take back, but that it was precisely the very great advantage that men enjoyed who worked at these furnaces which induced his council to prohibit their further building, as it was not likely that all the Yorkshire employers would follow suit, and they did not wish to have some of their men working under better conditions than others. To this decision the trade union adhered for nearly 20 years, and the consequence has been that hardly any glass bottles are now made in England.

I was reminded of this story when I saw in the newspapers, a short time ago, the bitter complaint of the glass-workers that foreign bottles were dumped in this country to the detriment of the native workmen. If these men had understood 25 years ago the principle that to lower the cost of production is to facilitate and increase the sale of an article, and thereby to benefit the whole community, themselves included, they would not have opposed the introduction of the tank furnaces, and they might also have remembered that competition would have forced all employers very soon to adopt this improved method of glass-melting, so that all the members would have worked under the same favourable conditions. Such a glaring case of short-sightedness does, perhaps, not occur very often, but this particular one has done irreparable injury to the manufacture of glass bottles in Yorkshire. Similar mistakes on the part of the trade unions can only be prevented by enlightening the workmen as to the necessity of lowering the cost of production, so that he uses his best endeavours to increase the output by adopting the latest methods and the best labour-saving machinery, and by convincing him that restricting the output means restricting employment.

(To be continued.)

YORK ELECTRICITY ACCOUNTS.

The following are abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., taken from the accounts of the York Corporation electricity department for the year ended March 31, 1904.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
To generation of electricity	2,662	14	6
Repairs, etc., of buildings and plant	383	15	11
Distribution of electricity	294	17	9
Attending and repairs to public lamps	448	6	1
Rents, rates, and taxes	348	7	3
Management expenses	772	13	2
Special charges—insurance	52	0	8
	4,962	15	4
Balance transferred to net revenue account	4,149	15	10
	£9,112	11	2

Cr. Income.	£	s.	d.
By sale of current	8,685	0	11
Rentals of motors and radiators	243	4	5
Miscellaneous	148	14	4
Stores on hand	35	11	6
	£9,112	11	2

BALANCE SHEET.

Dr. Liabilities.	£	s.	d.
Capital account—amount received	92,926	0	0
Sundry creditors	965	19	0
Owing to bank—capital account	6,593	11	1
Owing to bank—revenue account	2,254	13	1
Sinking fund accumulations	3,570	16	3
	£106,310	19	5

Cr. Assets	£	s.	d.
Capital account—amount expended for works	99,519	11	1
Sundry debtors for current supplied	3,013	13	10
Stores on hand	206	3	10
Sinking fund accumulations	3,570	16	3
Deficit balance on reserve fund account	0	14	5
	£106,310	19	5

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T.U.		924,263
Quantity sold { Public lighting 122,885 / Private consumers 643,657 }		766,542
Quantity used on works		44,485
Total quantity accounted for		811,027
Quantity unaccounted for		113,236
Number of lamps connected		53,454
Number of consumers connected		470
Maximum load demanded (kilowatts)		651

LEYTON ELECTRICITY ACCOUNTS.

From the accounts of the Leyton electricity department for the year ended March 31, 1904, the total expenditure on capital account to that date is stated to be £141,050. We give below abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
To generation of electricity	4,822	12	9
Distribution of electricity	243	8	6
Attending and repairs to public lamps	1,018	0	1
Rents, rates, and taxes	397	11	8
Management expenses, salaries, etc.	1,377	15	1
Law and parliamentary charges	19	10	0
Special charges, insurances, etc.	207	17	7
Total expenditure	8,086	15	8
Amount carried to net revenue account	9,508	1	10
	£17,594	17	6

Cr. Income.	£	s.	d.
By sale of current per meter	12,725	2	3
Public lighting	4,230	19	1
Rental of meters and other apparatus	397	14	0
Profit on repairs and work done	178	13	8
Rents receivable	10	10	6
Hire of instrument	51	18	0
	£17,594	17	6

GENERAL BALANCE-SHEET.

Dr. Liabilities.	£	s.	d.
Capital account—amount received	135,478	0	0
Sundry creditors	2,965	1	11
Amount due to treasurer (less cash in hand)	15,604	18	4
Self insurance fund	371	0	0
Consumers' deposits	496	11	4
Sale of gas plant (less amount carried to net revenue account)	801	0	6
	£155,716	12	1

Cr. Assets.	£	s.	d.
Capital account—amount expended for works	141,050	0	4
Stores on hand	210	16	9
Sundry creditors for current (less bad debts)	6,024	0	6
Net revenue account	8,431	14	6
	£155,716	12	1

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T.U		1,433,251
Quantity sold { Public lamps 390,142 / Private consumers by meter 804,802 }		1,194,944
Quantity used on works		72,719
Total quantity accounted for		1,267,663
Quantity not accounted for		165,588
Total maximum supply demanded (kilowatts)		854

Number of public lamps: 72 arcs, 658 incandescents.

Fire-Resisting Floors.—We have received an illustrated catalogue from Messrs. Hodkin and Jones, Limited, Havelock Bridge Works, Queen's-road, Sheffield, and 63, Finsbury-pavement, E.C., describing the corrugated-bar system of fire-resisting floors. The principal claims are strength, simplicity, and cheapness.

DUBLIN LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

Presidential Address.

BY MARK RUDDLE.

As it is not usual for your chairman's address to be followed by a discussion, the omission of this feature entails upon him a great responsibility in the selection of the subject matter upon which he should address you. Unfortunately, in the present instance, owing to ill-health and pressure of work, I have been unable to prepare an address which, in itself, would prove sufficiently interesting to entitle me to take advantage of this custom. I hope, therefore, that in the remarks which follow you will find ample material for your criticism, as in view of the rapid increase in our membership I propose to deal briefly with the method of training necessary for entrance into the profession we represent.

The right of electrical engineering to be termed a profession has sometimes been questioned by men who considered that manufacturers were too freely admitted into the ranks of the Institution, and that it had thereby been reduced to the rank of a mere trade union, but I think it is now admitted that we hold a clear title to rank as a profession, since our development has been mainly due to the efforts of a long line of experimenters and philosophers. Science, as Huxley says, is organised common-sense, and the groundwork of our claim to be a profession is the necessity for the exercise of all our past experience in the treatment of each problem as it arises—that is to say, for the application of those general principles unconsciously derived from all one has seen, or read, or thought about. The laboratory experiment of to-day is utilised in practical engineering to-morrow, and there is no other branch of engineering which so lends itself to exact mathematical treatment and demonstration. We have reason to be proud of the progress our profession—the youngest of the engineering sciences and arts—has made during the 25 years of its existence upon any appreciable scale. A century ago electricity seemed but a scientific toy; it is now thought by many to constitute the reality of which matter is but the sensible expression. The latest evolution of scientific research places the atomic theory in the background of ancient history, and the atom is now regarded as only the relatively vast theatre in which minute monads perform their orderly evolutions, the monads themselves being considered to be units of electricity operating by their interaction with the ether in which they are bathed. If this theory be true, it is small wonder that electrical science has of late years made such giant strides at a rate unparalleled in the history of the world.

It is unnecessary for me to weary you by detailing the multifarious applications of electricity in everyday work; new uses, and improvements of existing ones, so crowd upon our notice that it becomes practically impossible for an engineer in full work to keep himself abreast of the times in this respect in all branches of experiment and work. Every day is making more manifest the absolute necessity for specialisation in our profession, for, owing to the highly scientific and complex nature of the problems which have to be solved before arriving at a satisfactory method of meeting the demands of new applications and conditions, no one man can hope to have a thorough up-to-date knowledge of the whole cycle of professional work. This leads up to a most important point—viz., the training of electrical engineers with regard to their successful entrance into and practice of the profession.

A municipal engineer is often looked upon as an encyclopædia of information as well as a universal provider of employment, and parents frequently consult me as to the easiest way in which their sons can become trained electrical engineers, with, needless to say, a correspondingly satisfactory salary, and in the majority of instances leave me with a feeling in their minds that I am unduly magnifying the amount of study and training necessary before the first step can be taken upon the ladder of remunerative practical work. One frequently hears the remark made, "Oh! So-and-so is a 'born engineer.'" To a certain extent this is, of course, true, but in the ordinary meaning of the term, as implying that the person in question had no difficulty in acquiring his engineering knowledge, I venture to think that these "born engineers" exist only in imagination. Take, for example, a chick, which, upon coming out of its shell, is able to balance itself correctly, walk about, pick up food, and so on, thus showing it possesses the power of directing its movements to a definite end. How did it learn this very complex co-ordination of muscle, eye, and beak? It has not been individually taught; its personal experience is nil, but it has the benefit of ancestral experience, and in its inherited organisation are registered all the powers which it displays at birth. Man also carries with him the physical texture of his ancestry as well as the inherited intellect bound up with it, but this extends no further in the making of an engineer than giving the possession of a quick comprehension, a retentive memory, and a power of grasping problems. All else in modern engineering has to be acquired by a more or less tedious process of strenuous education. It is, of course, a well-known fact, but one of supreme importance, that actions, whose performance at first requires even painful effort and deliberation, may by habit be rendered automatic. Witness the slow learning of its letters by a child and the subsequent facility of reading in a man, when each group of letters which forms a word is instantly, and without effort, fused to a single perception. Instance the billiard player, whose muscles of hand and eye, when he reaches the perfection of his art, are unconsciously co-ordinated. Instance the musician, who, by practice, is enabled to fuse a multitude of arrangements, auditory, tactual, and muscular, into a process of automatic manipulation. I think, however, that the experts I have instanced would be the first to disclaim that their knowledge was born with them and to testify to the many years of mental and physical training necessary to attain to such facility of action. At least, such training is necessary to the vast majority of men. By myriad blows, to quote an old philosopher, the image and superscription of the external world are indelibly impressed upon our minds, the amount varying with the individual receptivity, due to ancestral inheritance and environment, and the immediate object in all systems of technical instruction is to so organise the course of study that the ultimate result shall be attained with the least possible waste of time and effort.

I shall not attempt to place before you to-night any cut-and-dried scheme or syllabus embracing the whole art of training an electrical engineer, for that at present seems to be a matter with regard to which the most diverse opinions are held by the leading experts in technical education. All of you will, no doubt, have in your minds the very exhaustive paper presented by Dr. Walmsley to the meeting of the Institution in London on Feb. 11 of this year, and the prolonged discussion which ensued thereon, and it is a serious matter to find that even now no one settled plan seems to meet with general approbation. This is greatly to be regretted, for upon the system of technical education to be pursued in the near future rests largely the position which will continue to be held by the Empire in the commercial markets of the world. Notwithstanding our backwardness in this matter in comparison with many parts of the Continent, we have hitherto managed to hold our own, being largely assisted by the natural resources of the country, but competition is becoming more keenly felt every year, and we cannot afford to drift along in the same old careless way.

The task of keeping the training of students for the profession of electrical engineering abreast of current practice seems almost hopeless in the face of the present rapidly increasing rate of development, and this leads to the important question whether it is advisable for the various colleges and technical schools to confine themselves to the teaching of the scientific principles which underlie engineering in general and the electrical branch in particular, or whether they should supplement that course by practical information upon the construction and operation of the various types of machines themselves, which would, of necessity, require that the equipment should be kept up to date by the newest and most efficient types of actual plant. The latter plan has actually been tried in practice, and the following figures from Dr. Walmsley's paper will show the scale of the experiment: In America the capital expenditure upon buildings and equipment for technical education amounts to no less than £75,000,000, of which £10,590,000 is devoted to engineering purposes. The annual income for 1901 is given as £9,623,200, of which the engineering sections received £1,527,000. The number of students in that year reached a total of 98,000, of which the engineering section formed 14 per cent. It might, therefore, be fairly thought that for this enormous outlay a good working system would have been evolved. Judging, however, from the paper itself and the lengthy discussion which followed, this has not been the case, and complaints have been made that the workshop and laboratory equipment has been on such a lavish scale that the students have been rather overloaded with a large and confused assortment of facts, and that the training in general principles has thereby necessarily suffered. In these countries we have not had the privilege of suffering from over-lavish equipment of our training institutes; on the contrary, for want of the necessary funds it has been cut down to the lowest point, but the general effect seems to be the same, and the trained students do not appear to be thoroughly equipped for entrance to the profession.

One predominant fact appears certain—namely, that one course of general training is necessary for those men who have the ability and funds for qualification into the higher branches of the profession, and that an entirely different training is required for those who, under ordinary circumstances, will have to commence their career with the routine work of the many applications of electrical engineering. By the higher branches I mean men who intend to devote themselves more particularly to original research and to the

Digitized by Google

theoretical development of the scientific side of the profession, but this section is outside the scope of my present remarks. I feel more concern for what I may be excused for terming the rank and file of the profession, each one of whom, nevertheless, carries a marshal's baton in his knapsack, if he has been properly trained and qualified to seize the opportunity when it occurs.

The question seems to hinge largely upon the syllabus of the primary and secondary education received up to the age of 16. This should have comprised, in addition to the ordinary subjects of general education, a good grounding in algebra, euclid, elementary physics, and, if possible, either French or German, or both. If in the secondary school there is even a small workshop, a very valuable amount of knowledge could be imported in the elementary principles of simple tools and machines. Whatever the course of training to be pursued after this age, full advantage cannot be taken of it if the secondary education has not been directed with a definite idea of the engineering object in the future, for inadequate preparation means that much valuable time must be lost in preparatory work after leaving school. After this period two general courses of training are open to the student, each having strong advocates and, consequently, neither giving universal satisfaction. First, he may enter a suitable engineering works and spend two to three years in learning as much as possible of machine work, turning, fitting etc., together with some experience of drawing office work. After this, having gained an insight of practical everyday work, he may then enter an engineering college for thorough training in the theoretical side of his work. On the other hand, he may, on leaving school, at once take up theoretical work in a well-equipped technical college, and after, say, a three years' course, he may enter an engineering works with an eye to one particular branch of professional work or to gain all-round experience. The latter course has much to recommend it, as there is then no break in the educational course such as must occur if the student goes into a workshop straight from school, and after leaving the latter, has to resume the habit of learning and of routine study, which is not always an easy task. It is also not advisable in all cases for youths to be subjected at such an early age to the influences of ordinary workshop life, which they are not always able to withstand and find difficult to shake off on entering the training college; while if he first enters the latter, his character will be sufficiently formed when the time comes for leaving.

There is, however, a middle course which is often recommended for those students who are unable for various reasons to spare sufficient time to take full advantage of the general training I have mentioned—that is, to enter a works for practical training and to work up the theoretical side in evening classes. Except where no other course is possible, I do not recommend this plan. It is hard for a youth of 16 or 17 to keep ordinary shop hours at mainly physical work and to give up the majority of his evenings to private study or attending technical classes, and I am not sure that it is unattended with danger to his proper physical and mental development. A growing youth must have time for recreation and rest, and success is dearly bought at the expense of a debilitated constitution. Still, there are cases in which there is no option but to pursue this plan; but men so trained cannot expect to compete on equal terms with those who have had a more liberal course of study, except in cases of unusual ability and aptitude.

Much, however, depends upon the student himself. If he has an innate love of the science and art of electrical engineering, and of learning for the sake of finding out hidden things; if he has the earnest desire to attain to as near the front rank as his capabilities will permit, and has the physical and mental constitution to stand the strain of burning the candle at both ends, so to speak, he will, with average good fortune, attain his end more surely than many others who start under more, apparently, favourable auspices, for, having the self-stimulus of an insatiable knowledge-hunger, he is in closer sympathy with his teachers, and does not wait to be spurred on in his work. And this is the true spirit which should animate those seeking to enter our profession. Its devotees must give more than lip-service—answering of examination questions and obtaining passes and certificates—for, as you know, these alone are no test of a man's fitness, and, in fact, are often the cause of much wasted time by giving a premium to those who best develop a parrot-like facility of answering set questions rather than probing the depth of the information they have assimilated. In saying this, I must not be taken as considering these examinations entirely useless, for they undoubtedly do serve a useful purpose in separating the earnest student from the merely brilliant one. The failures in formal examinations often provide the most reliable raw material to be worked up afterwards, as only those who have grit in them continue to persevere as usual in spite of their failure to pass, and this determination to persevere stands to them in their after career, for it must never be forgotten by those who would be successful that they must be students all their lives. There is no such thing as finality in the knowledge of electrical engineering—a week now is more pregnant with discovery than 100 years was formerly, and those who desire to keep in the front ranks must keep pace with the times in their special spheres of work.

A serious danger is now developing owing to the great inrush of young men into anything electrical in name; many of them seem satisfied to acquire just enough technical knowledge to secure a post. Once secured they settle down and perform their routine duties more or less thoroughly, and gradually drift out of keeping their training up to date. Football, cricket, cycling, and often matrimony, or the preliminary stages of it, claim their leisure hours entirely, and even when on duty occupy such idle moments as occur between the intervals of actual work in the perusal of sporting or sensational literature rather than in anything bearing on their professional work. Time goes on, and opportunities occur for promotion or for entering fresh fields of work, and they find they stand no chance against competitors of more modern training from not having kept their knowledge up to date. It is not enough to have sufficient knowledge for present needs; one must look ahead, and be prepared for developments.

I have hitherto dealt principally with the technical side of a student's training, but before a student can expect to secure a position of any importance he has yet to acquire the commercial or business side of his education. No technical training institute can teach a student how to handle workmen, or how to turn out finished plant from a workshop at commercially remunerative prices, nor would it be reasonable to expect it to do so, for such knowledge can only be gained in the hard school of practical experience, and learnt little by little as opportunity offers. And yet such is the ultimate object of all profession training in the majority of cases, for the most perfectly and scientifically designed scheme is quite valueless unless it can be made a commercially financial success. Students should, therefore, take every opportunity of seeing works in practical progress; they feel utterly at sea with regard to much that goes on, but to an observant mind there are many object lessons to be learnt and hints obtained which will be of much service in after life. I have often been struck with the apathy displayed by the majority of students when given the opportunity of visiting works in process of erection, or in actual everyday running; they ask no questions, and apparently look upon the whole thing as a bore, or an opportunity of escaping a regular class lesson at best, instead of regarding it as a unique chance of seeing practical engineering works and life into which they may hope one day to enter. It is most depressing to those who have to show them round and desire to make the visit interesting and instructive to those who may be their colleagues or successors at some future time to find that so little interest is taken in what is going on, and they feel quite relieved and grateful when one of their visitors asks the most trivial question upon any point. Ask questions about everything is my advice to students; never mind whether they may appear foolish or trivial, give evidence in some way that you appreciate your opportunity, and you will gain many valuable hints for your future work, and render the task of your instructors a little easier.

I may here express a word of sympathy for the teachers and instructors in technical institutions, for theirs is, indeed, a difficult task. Too often they are unjustly blamed for being unable to meet the demand for trained men to fill the ranks of workers in technical industries, but they do not always deserve that reproach. Some there are, no doubt, who become teachers because the position gives them the means to live, but I know of many earnest capable men who are animated by a keen desire to fit their pupils in the best possible way to meet the battle of life, and yet are handicapped by themselves not having a practical knowledge of technical work and the requirements of employers in the various industries. They are, therefore, unable to so shape their course of training that it prove suitable, and being themselves cognisant only of a college course they naturally follow on the same lines. This is not altogether their fault; it reflects mainly upon the leaders of industry and large employers, who for the most part take but little interest in the training of the raw material from which their employés are drawn, and who have not realised that it is to their own interest, as well as that of the country at large, that they should co-operate with the teaching bodies, and assist them by both advice and funds in being properly provided with the most suitable staff and general teaching equipment.

I think I have detained you long enough upon this subject for to-night, and I would now say a few words upon the work of our local centre. The standard of papers read before you has been well maintained during the past session, and, in fact, one or two have seemed almost too high class for a large number of the members, though not for the credit of our centre. I judge of this by the very limited amount of discussion which ensued thereon, and, with all due deference

Digitized by Google

to my hearers, I cannot but feel it somewhat of a reproach that so few members can be got to join in the discussions, even upon subjects with which most of you are familiar in your everyday business. This should not be. It is not quite fair to expect the same men to speak upon every occasion, and it does not tend to elicit the most profitable discussion upon the particular subject. This, I venture to say, is a great loss to all of us, and takes away largely from the main object of our meetings, which should be the advancement of our mutual knowledge, and, therefore, the interests of the profession at large. I would, therefore, appeal to our hitherto silent brethren to help us in the future ; it is not necessary to make a long speech, a few words of practical experience straight to the point are worth infinitely more than a long dissertation couched in ornate phraseology but adding little or nothing to our information. Everyone should endeavour to contribute his mite to the discussion ; it may not be easy at first to unpractised speakers, but it will improve with practice, and it is most valuable training for students. A more general discussion would enable us to invite shorter papers from members, and this in turn would remove much of the present difficulty in getting members to contribute papers. In most instances a paper taking 15 to 20 minutes to read would furnish ample material for 1½ hours' discussion, and would not be such a tax upon the contributor as a more elaborate paper lasting an hour or more.

Our honorary secretary informs me that there is such a scarcity of papers in view that he may have to fall back upon a visit to the Corporation electricity works to fill up a gap in the meetings. I need hardly say that the Lighting Committee will be ready to facilitate such a visit, as the chairman has always taken a keen interest in the work of our centre, but I hope is will not be necessary to take up one of our few regular meetings in this way, as, if the members desire, it can be arranged instead for some Saturday afternoon, when the generating station could be inspected under more favourable conditions.

In conclusion, gentlemen, I have to thank you for your attendance here to-night, and to express the hope that at the close of the present session our proceedings will show that we have made substantial progress in advancing the interests of the profession to which we have the honour to belong and of the Institution which officially represents it.

ST. PANCRAS.

The late mayor of St. Pancras, Mr. T. H. W. Idris, in his address to the Council on his retirement from office, gave a most interesting review of the work of the past year. His retrospective notes as to the early attempts at gas lighting in the district are quite historical. Speaking on the electricity undertaking he said :

Before dealing more fully with important matters connected with the electricity undertaking, I think we are justified in congratulating ourselves on the splendid progress we have made. The handsome profit of over £20,000 for the past year, after repaying all costs of production and distribution of the current, repaying a considerable portion of borrowed capital, interest on loans, and all other charges, is a result which other authorities would have liked to emulate. Considering that we are the pioneers of municipal electricity in London, that we have had to gain experience and overcome many difficulties, and that our charges for current are amongst the lowest in the Metropolis, we may say to-day without egotism that we have achieved a remarkable success. During the past year we have, perhaps, had rather more than our share of trouble in connection with this undertaking. Several owners and occupiers of property abutting on our King's-road central power station entered an action against the Council alleging nuisance, noise, and annoyance from vibration, etc., from the refuse destructor and the electricity works. Unfortunately, the late vestry, when they acquired the land for the station, had to obtain it by agreement, inasmuch as they had no power to promote a Bill at the charge of the rates for compulsory purchase giving a statutory right to use the land for generating electricity thereon.

As is generally the case in these circumstances, the local authority got the worst of it, and an injunction was granted which would have become permanent unless all vibration had been stopped, which was almost an impossibility. The result is that we are purchasing the interests of the persons concerned, at what are no doubt in many cases exorbitant prices. We had practically no option in the matter. As a result of this action you thought it was very necessary that some steps should be taken with a view to preventing similar arbitrary and unjust proceedings being taken in future, and at least putting electric lighting undertakings in no worse position than other undertakers who have statutory obligations imposed on them. A conference was, therefore, called of all local authorities and companies owning electricity undertakings in the country, with the object of petitioning the Board of Trade to promote legislation on behalf of electricity undertakers for obtaining compulsory powers of purchase of land for their purposes, and for the amendment of the Electric Lighting Acts, with a view to repealing the nuisance clause and preventing actions being brought against the undertakers in all cases where the works are carried on without negligence. I was elected to the chair of the conference, which was well attended by representatives from all parts of the kingdom, and the subject was very fully discussed, and the conference appointed a committee to formulate propositions for action. This committee subsequently approached the President of the Board of Trade, and asked him to receive a deputation in support of the resolutions (one of which referred to the Supply of Electricity Bill) passed at the conference. A reply was, however, received from the President, suggesting that as the Supply of Electricity Bill then before Parliament had been referred to a Select Committee of the House of Lords, the best course for those interested would be to submit their views to that committee.

I may remark in passing that, with regard to this Bill, you had already presented a petition for the elimination of Clause 6 (1), inasmuch, as if it had been passed as drafted, it would have been possible for a company to enter into competition with the Council in the borough. As the matter was of urgent importance, and the Bill was to be in committee in a short time, I took the responsibility of having petitions prepared, both on behalf of the Council and of the conference, praying for an addition to Clause 1 of the Bill, which would have the effect of placing electricity undertakers, who had acquired their land by agreement, and not under statutory power, in a position to successfully defend actions in respect of vibration, etc., so long as the works were carried on without negligence, and also in regard to the Council's petition for the elimination of Clause 6 (1), and praying that we might appear by counsel and witnesses in support of the petitions. My action in the matter was approved by you, and the conference also signified its approval. The prompt action on our part had the effect of obtaining very valuable amendments to the Bill. The interview we had with the assistant secretary to the Board of Trade resulted in the Board agreeing to amendments which the Select Committee agreed to insert, and made the Bill very satisfactory to all electricity undertakers.

Briefly, the Bill as amended will give undertakers power to apply to the Board of Trade for a provisional order to acquire or use land already in their possession for generating, converting, or transferring electricity. A clause was also inserted providing that what is known as the nuisance clause should not be incorporated with a provisional order, so that if works included in an order are carried on without negligence, no person would be entitled to claim compensation for nuisance, and there would be no power to grant an injunction to close the works. Other clauses were included in the Bill which I need not specifically refer to, but which would be of benefit to electricity undertakers.

All electricity undertakers are indebted to Mr. Morse (solicitor to the British Traction Company), Mr. Gripper (managing director of Edmundson's Electricity Corporation), Alderman W. H. Matthews, Councillor G. Hickling (chairman of our Electricity Committee), Councillor J. Bussey (chairman of the Electric Lighting Committee of the Poplar Borough Council), Mr. R. M. Prescott (town clerk of Fulham), and Councillor S. Slatter (of the Barnes Urban District Council), to whom the supervision of the opposition of the conference was referred, for the zealous attention they devoted to the work, which meant attendance at frequent consultations and in the committee room of the House of Lords during the time the Bill was under consideration ; and our best thanks should be tendered to them for the valuable services they have rendered. The Bill, as amended by the Select Committee, was passed by the House of Lords, but owing to the prorogation of Parliament its further progress was stopped. I do not think there is much doubt that it will be reintroduced into Parliament next session, probably by the Board of Trade in its amended form, and we all hope will then become law. We may, I think, congratulate ourselves on the measure of success of our labours in this direction, which I feel sure will eventually bear a fruitful result.

Before leaving this matter, I desire to express the obligation we are under to Mr. Richards (the deputy town clerk), who acted as honorary secretary of the conference, to Mr. Baynes (our chief electrical engineer), to Mr. Blair (our borough engineer), and to Mr. Pycraft (the chief clerk of the electricity and public lighting department), for the unremitting and painstaking services rendered by them in connection with the opposition of the Council and the conference to the Bill in order to obtain the amendments referred to, these services being in addition to their regular duties, and necessitating working not only during the day but long after the office hours.

COMPANIES' MEETINGS AND REPORTS

CAPE ELECTRIC TRAMWAYS.

The report of the Cape Electric Tramways Company for the year ended June 30 last states that the profit and loss account shows, after providing for debenture interest and redemption of debentures, a net balance to credit of £57,080. From this sum the directors have paid to the shareholders 10 per cent. upon their capital, represented by two interim dividends of 5 per cent. each, paid on Jan. 28 and on Aug. 17 respectively. The reserve fund has also been credited with the sum of £8,000, making a total appropriation of £56,000, and thus leaving a balance of profit of £792 to be carried forward. The passenger and revenue returns for the Cape Town system for the 12 months under review both show a slight increase over the previous year, and the expenditure account a small decrease over the same period. An increase of passengers and revenue has also been experienced in Port Elizabeth; but the expenditure account of that system has had to bear several very heavy charges during the past 12 months, due principally to the necessity for constructive repairs to the permanent way, to a serious increase in the coal account, and to other special items, amounting in all to about £6,000. At the commencement of the year 1904 the Board appointed an independent general manager for the Port Elizabeth system—Mr. J. A. Barkley—and the directors are glad to be able to now state that the improved condition of this system and the decreasing expenditure have fully justified them in this measure and in the selection of the present manager to the post in question. At Cape Town, during the year under review, the important extension of Hanover-street was opened to traffic. At Port Elizabeth the Board had sanctioned an extension on the Walmer-road to the municipal boundary, which is now being proceeded with, and on completion of the same an extension on the Cape-road, also in the direction of the municipal boundary, will be taken in hand. These two extensions are amply justified by the increase in the number of suburban residences in these districts. As regards the power-house at Port Elizabeth, the additional unit referred to in last year's report has since been completed, and is working in a satisfactory manner. The Camps Bay tramline, leased from the Cape Town Consolidated Tramways and Land Company, Limited, by this Company, has not hitherto proved the success that was anticipated, owing to industrial depression. The loss on the year's working, including the rent paid to the Consolidated Company, amounts to about £9,000.

ROSARIO ELECTRIC.

The ordinary general meeting of the Rosario Electric Company, Limited, was held on Monday at River Plate House, Mr. W. T. Western presiding.

The **Chairman** said that at the time of the last annual meeting the Company was transferring from its old system to a new system. The Company had now done what it had contemplated, and the results had been satisfactory. The new engines and cables had been taken over in August, 1903, so that the Company had up to the date to which the balance-sheet was made up had 10 months' use of them. Up to last Christmas the staff in Argentina had been practically occupied in transferring the Company's customers from the old system of cables to the new one, so that naturally the Company did not get much benefit from the new machinery during that period. After Christmas, however, business went ahead. After deducting the running expenses in Argentina, the profit for the first six months of 1903 amounted to £2,700, and for the six months to Dec. 31, 1903, they had risen to £2,800, while for the six months to June 30, 1904, they had advanced to £5,100. For the first two months of the Company's current financial year the figure was over £2,400. The number of customers had risen from 800 in December, 1903, to 936 in September last. Besides taking on new consumers for lighting, the Company had made a beginning in the power business.

The report was adopted.

A resolution was passed to increase the capital of the Company to £160,000 by the creation of 8,000 further 6 per cent. cumulative preference shares of £5 each, ranking *pari passu* with the existing preference shares.

In future dividends will be paid half-yearly.

The resolution was carried.

A separate meeting of preference shareholders was subsequently held, and the creation of the new preference shares was agreed to.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH.

For the half-year ended June 30 the directors report that the gross receipts have amounted to £300,057, against £265,099 for the corresponding half-year of 1903. The working expenses, including £25,712 for maintenance of cables, absorb £141,707, against £138,516 for the corresponding period of 1903, leaving a balance of £158,350, the net profit being £143,378. After adding £41,890 brought forward from the previous half-year, there is an available balance of £185,269. Two quarterly interim dividends of 1¼ per cent. each, amounting to £75,000, have been paid for the half-year, leaving a balance of £110,269 to be carried forward. During the half-year a further partial renewal of the Hong Kong-Foochow cable has been effected, and the cost, amounting to £6,273, charged against the general reserve fund. The s.s. "Restorer" has been sold to replace the Commercial Pacific Cable Company's s.s. "Scotia," and a small steamer (s.s. "Magnet") has been purchased for effecting repairs ro the many cables which the Company possesses in shallow waters of less than 400 fathoms. The subsidy arrangement in connection with the Tonquin cable expired in February last, and a new agreement has since been arranged, subject to parliamentary approval, by which the French Government will acquire the ownership of the cable.

WESTERN TELEGRAPH.

The sixty-second ordinary general meeting of this Company was held at River Plate House, Sir John Wolfe Barry, K.C.B., presiding.

In moving the adoption of the report and accounts (particulars of which appeared in our issue of the 28th ult.), the **Chairman** stated that since the conclusion of the period under review the general aspect of trade, which had been reflected in their receipts, was, on the whole, promising.

In reply to questions, the **Chairman** said that he thought wireless telegraphy would be a kind of "handmaid" to the cable system.

The report was adopted.

LEGAL INTELLIGENCE.

CHEPSTOW GAS COMPANY v. CHEPSTOW ELECTRIC LIGHT AND POWER COMPANY.

An appeal by the defendant company came before the King's Bench Division last week.

The local magistrates had convicted the electrical company for laying their mains in undue proximity to those of the gas company, and contrary to the provisions of the statute. It was proved that the electrical company did not give the gas company notice, as provided by Section 18 of the Electric Lighting Clauses Act, 1899, before commencing to sink trenches, but prior to the arbitration which preceded the proceedings before the magistrates, the gas company had given notice that they did not claim penalties under that section. The arbitrator assessed the amount of the damages to be paid to the gas company, but did not order the removal of the defendants' wires, this being outside his province. The Act provided for a penalty during every day of default after conviction, and the magistrates imposed a fine of £1 and costs, and a daily penalty of £1 during default. The defendants appealed against this to the High Court, contending that the summons issued against them only alleged an offence under the statute, and did not comprise daily penalties. Further, they contended that a conviction for a penalty and for future offences was bad upon the face of it.

Mr. Shiress Will, K.C., on behalf of the defendants, argued that before a daily penalty could be imposed there must already be a conviction. He contended, further, that the offence was not a continuing one, as the damage sustained by the gas company was purged by payment of compensation as directed by the arbitrator. In addition, he contended that the time-limit of six months invalidated the prosecution.

Mr. Macmorran, K.C., for the gas company, argued that the Act contemplated penalties in addition to the compensation if the offence was not discontinued. The arbitrator had awarded a small sum for compensation, evidently on the assumption that the grievance would be remedied. He contended that the offence was of necessity a continuing one.

The **Lord Chief Justice** stated the Act clearly provided for penalties in addition to compensation. In regard to the contention that the connection was bad because it imposed a daily penalty beyond the fine of £1, counsel for the plaintiff had admitted that penalties for future offences could not be added, especially as it was provided by the Act that the penalty for default did not operate until after conviction. Respecting the time-limit, he could not adopt the defendants' view that this should be reckoned from the date of the notice served by the gas company. The dispute was in progress for some months after this, and upon the conclusion of the arbitration the gas company had served a second notice.

Kennedy and Bruce, J.J., concurring, the appeal was dismissed, with costs.

SPEED OF TRAMCARS.

William Drawbridge and Arthur Miller, tramcar drivers in the service of the London County Council, were summoned by the police for driving their cars along Clapham-road at an excessive rate of speed. It was stated that a member of the police had by the aid of a stop-watch timed the defendants' cars over a distance of 220 yards. The time occupied was 38 seconds, representing between 11 and 12 miles an hour.

A difficulty arose owing to the absence of the police officer on a holiday.

Under these circumstances the summonses were withdrawn.

ELECTRIC LIGHT ACCOUNT.

The adjourned summons against William Hunter for non-payment of his account of £3. 1s. 11d. for the supply of electric energy by the Aston Corporation was again before the local magistrates on the 4th inst. A report of the case appeared in our last issue, the matter being then adjourned for the production of the meter which caused the dispute.

The **Town Clerk** (Mr. Joseph Ansell), representing the Corporation, explained that the difficulty had arisen from the fact that the figures registered by the meter ought to have been multiplied by four, the reason for which was described in our last issue. It was a regrettable fact that the department did not supply to the consumers that infor-

Digitized by Google

mation. To meet that difficulty the department undertook to reduce the charges by 25 per cent. up to April 25. Mr. Ansell urged that defendant had not been charged for any electrical energy beyond that which he had consumed.

Defendant, in reply to the magistrates, said that he was told that he had consumed 32 units, and it was for this he understood he would have to pay. He did not accept the statement that it should be multiplied by four, but had no evidence to offer against that interpretation.

Mr. C. Wallis (one of the magistrates) said that the defendant had a right to know from day to day what he was consuming.

After a consultation, the magistrates made an order upon defendant to pay £1. 16s. 6d.

PERSONAL.

The Wigan County Borough Council have increased the salary of Mr. Slevin, electrical and tramways engineer, from £300 to £450 per annum.

The Pontypridd Council have appointed Mr. Teasdel, Cardiff, resident manager of the electric lighting and tramways undertaking at a salary of £300 per annum.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Melbourne.—The Federal Postmaster-General requires tenders for 6,000 yards of telegraph cable. Tenders by Nov. 15.

Porto Alegro (Brazil).—The term for receiving tenders for an electricity station, already announced, has been prolonged to Nov. 30.

Banza (Spain).—The Municipality requires tenders for the electric lighting for five years. Particulars from the Alcalde, Banza (Jaen).

Guirgia (Roumania)—Tenders are required for the electric lighting of the town. Particulars from the town's secretary. Tenders by Jan. 28, 1905.

Hammersmith.—The Council invites tenders for the supply of (1) extra high-tension feeder mains and (2) draw boxes, frames, covers, etc. Tenders by Nov. 16. See advertisement.

Manchester.—The Tramways Committee invite tenders for the supply, delivery, and erection of one 15-ton and two 5-ton electric overhead travelling cranes. Tenders by Nov. 22. See advertisement.

Erith.—Tenders are invited for material and work in connection with the installation of electric light at the Education Committee's offices at Picardy, Belvedere. Tenders by Nov. 11. See advertisement.

Caen (France).—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1, 1905.

Liege.—Tenders are required for the construction and working (concession) of three electric tramways. A deposit of £400 is required. Particulars from the Provincial Government, Liège. Tenders by Nov. 14.

Hammersmith.—The Guardians invite tenders for a complete wiring installation for the electric lighting of their new workhouse and infirmary at Wormwood Scrubbs. Tenders to the Clerk to the Guardians by Nov. 15.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Johannesburg.—The Municipal Council invite tenders for two 35-ton electric overhead travelling cranes and transformer pillars and switchgear. Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W., and received by them not later than Dec. 27.

Rotherham.—The Corporation invite tenders for wiring the new isolation hospital buildings in Badsley Moor-lane. Specification and forms of tender at the office of the Borough Electrical Engineer, Rawmarsh-road. Tenders to be sent to Mr. W. J. Board, town clerk, Town Hall, Rotherham, by Nov. 21.

Ballinasloe (Ireland).—The Committee of the District Lunatic Asylum invite tenders for wiring the temporary buildings for 35 incandescent lamps of 16 c.p. each, at a pressure of 200 volts, and the necessary overhead cables to connect same with engine-house, and all else necessary. Tenders by Nov. 14.

Glasgow.—The Governors of the Glasgow and West of Scotland Technical College invite tenders for a complete wiring installation and switchboards for the electric lighting of their new buildings. Specification may be obtained from Mr. H. F. Stockdale, secretary and director, 38, Bath-street, Glasgow, to whom tenders must be delivered by Nov. 26.

Brussels.—Tenders are invited for the construction of an electric generating station and other works in connection with the establishment of a goods station at Brussels. The estimated cost of the work is about £4,367. A deposit of about £280 is required to qualify any tender. Specifications (price 1s. 10d.) and farther particulars may be obtained from M. De Rudder, Administrateur des Voies et Travaux, 11, Rue de Louvain, Brussels.

Burslem (Staffs)—Tenders are invited for the supply and erection of the following electric lighting plant at the workhouse, Chell, for the Guardians of Wolstanton and Burslem Union: (Section A) water-tube boilers, with fittings; (B) feed-water heater, feed pumps, piping, etc.; (C) two 25-kw. steam dynamos and booster; (D) switchboard; (E) cables and wiring; (F) accumulators; (G) arc lamps. Tenders to Mr. J. A. Lowndes, clerk, by 12 noon on Nov. 15.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, London, E.C. Tenders by March 31.

Dundee.—The Town Council invite tenders for the relaying of the present copper strip feeder main throughout the town with insulated cables. Specifications may be had on application to Mr. H. Richardson, A.M.I.E.E., city electrical and tramways engineer, Dudhope-crescent-road, Dundee, on payment of 40s., which will be returned only on receipt of a bona fide tender. Tenders to Mr. W. H. Blyth Martin, clerk to the Council, City Chambers, Dundee, not later than first post on Nov. 12.

Sydney.—Tenders will be received at the office of the Acting Deputy Postmaster-General, Sydney, New South Wales, up to 2.30 p.m. on Dec. 28, for the supply and delivery at the Departmental Stores, Sydney, of telegraph, telephone, and electric light material. Specifications and general conditions may be seen and tender forms obtained at the General Post Offices, Sydney, Melbourne, Brisbane, Adelaide, Hobart, and Perth. Samples may also be seen at Sydney, Melbourne, Brisbane, and Adelaide.

Manchester.—The Electricity Committee invite tenders for the whole of the work required in connection with the wiring for arc and incandescent lighting of Stuart-street generating station. Specifications may be obtained on application to Mr. F. E. Hughes, secretary, Electricity Department, Town Hall, Manchester, on payment of a fee of £2. 2s., which amount will be refunded on receipt of a bona fide tender. Tenders to be addressed to the Chairman of the Electricity Committee, and delivered at the Town Hall, Manchester, by 10 a.m. on Nov. 11.

Belfast.—The Town Council invite tenders for the following tramway works, equivalent to about 70 miles of single track: (1) permanent way, road-bed, paving, and bonding; (2) overhead electrical equipment; (3) underground feeders, telephone and test wires, spare conduits, etc.; (4) steam dynamos, switchboard, also three-phase plant, condensing plant, overhead traveller, station lighting, etc.; (5) boilers, superheaters, mechanical stokers, economisers, coal and ash conveying plant, steam exhaust and feed pipes, pumps, etc.; (6) double-deck electric tramcars. Tenders must reach the Town Clerk's Office by 18th inst., at noon.

Brisbane.—Tenders are invited by the Deputy Postmaster-General for the supply and delivery at the Telegragh Office Yard, Thursday Island, of 100 tubular wrought-iron telegraph poles to Specification No. 11 and Schedule No. 51, and also for the supply and delivery at the cable tanks, Thursday Island, of three nauts of submarine cable to Commonwealth Specification No. 8 (Queensland, No. 22) and Schedule No. 50. Tenders by Dec. 12. They must state the time required for delivery; this time will be counted from the date of the notification of the acceptance of the tender. Specifications and forms of tender can be obtained at the General Post Offices, Sydney, Melbourne, Brisbane, and Adelaide. Neither the lowest nor any tender will necessarily be accepted. Tenderers are required to note that Customs' duties must be included in all charges, as per clause 2 of the general conditions. All tenders sent by post must be registered.

RESULTS OF TENDERS.

Limerick.—The Electric Lighting Committee have accepted the tender of Harrison Lee and Sons for the erection of a tank at the power house at £220.

Dudley.—The Electric Lighting Committee have accepted the tender of E. Seckerson, Stourbridge-road, Dudley, for extension of offices and erection of workshops.

Ipswich.—The Corporation have accepted the tender of Chamberlain and Hookham, Limited, Solar Works, New Bartholomew-street, Birmingham, for the supply of continuous-current meters.

Salford.—The Electricity Committee have accepted the offer of the Salford Oil-Refining Company to supply 25 barrels of crank-chamber oil, similar to that previously supplied, at 1s. 2d. per gallon.

Northwood (Uxbridge) — The Hart Accumulator Company, Limited, have been awarded the contract for the supply of storage battery, consisting of 278 of their standard central-station type cells.

Abergavenny.—The following tenders have been accepted for lighting the asylum: engine and battery rooms, J. G. Thomas and Sons, Abergavenny, £1,140; lighting plant, etc., Woods, Slacke, and Co., £2,364; wiring and fitting, Scott and Mountain, £2,640.

BUSINESS NOTES.

TRACTION.

Royton.—The Board of Trade have approved the tramway, which has been opened to the public.

Stockton.—The Corporation are in communication with the tramway company in reference to "those noisy trams."

Wolverhampton.—Three petitions have been presented for the reopening of the abandoned route from Coleman-street to Newbridge.

Stockport.—The Local Government Board have formally sanctioned the purchase of the Hazel Grove tramway undertaking by the Corporation.

Digitized by Google

West Hartlepool.—The Corporation have decided to take proceedings against the tramway company with respect to the latter's failure to keep the track in good condition.

Dudley.—The Tramway and Electric Lighting Committee recommend that the application to the Board of Trade for the appointment of a referee in connection with the dispute with the company be proceeded with.

Halifax.—The Corporation have decided to double the tramlines from the loop near St. Jude's Church to the junction of the main road on the north side of Savile-park and Skircoat Moor-road at an estimated cost of £2,041.

Blackburn.—The six months ending Sept. 30 are estimated to show a net profit, compared with a loss of £690. 16s. 9d. for the corresponding period of 1903. The traffic this year has received a tremendous impetus from the fine weather.

Kilmarnock.—Arrangements have been made to start the tram service on the 10th prox., when Lord Howard de Walden will perform the inaugural ceremony. The consulting engineers were Messrs. Kennedy and Jenkin, and the work has been carried out most expeditiously.

London County Council.—The Act obtained by the Council in 1896 authorising the construction of tramways over the new Vauxhall Bridge does not sanction the use of electric traction. The Highways Committee recommend that powers be applied for in the next session of Parliament.

Trafford Park Estates, Limited.—The annual report shows a net profit on estate railways and tramways amounting to £949. The Manchester and Salford Corporations have entered into an agreement to run their electric cars over the company's tramways for a period of about 20 years, paying the company the profits earned thereon.

Erith.—The work of laying the tramways is in full swing. Operations have been commenced at Northumberland Heath and Abbey Wood, and in a short time a start will be made at Northend. From these three points the workmen will make for the railway bridge near the Wheatley Hotel, which has been marked out as a centre.

Penge.—The Urban District Council have adopted the following resolution: "That the Tramway Committee at the ordinary November meeting of the Council, or earlier if expedient, do present a report on the position of the Penge arrangements with the British Electric Traction Company in order that a comparison be made between the Beckenham tramway scheme and that of Penge."

Cardiff-Penarth.—A meeting of the Penarth District Council was held on Monday, when a resolution was moved that the consent of the Council be given to the Penarth syndicate to lay a line between Cardiff and Penarth, subject to their agreeing to the conditions laid down by the Council. The matter had previously been before the Council, who refused consent. It was decided to consider the matter again at the next monthly meeting.

South Shields.—The Rural District Council have appointed a committee to consider the question of obtaining powers for constructing an electric tramway from the terminus of the Sunderland borough tramways in Sea-lane, Roker, to the terminus of the proposed Corporation tramways in Sunderland-road, South Shields, and to enter into communication with the Sunderland and South Shields Corporation on the subject. The two towns are seven miles apart.

Reading.—The returns for the four weeks ending Oct. 20 show that the cars ran 65,668 miles, and carried 591,253 passengers. The total receipts were £2,505. 5s. 11d. The tramways manager has received from the Board of Trade a copy of the revised regulations with regard to the use of electrical power on tramway lines for preventing fusion of or injurious electrolytic action on gas and water pipes, etc., and for minimising injurious interference with the apparatus of other undertakings.

Mitcham Light Railway.—A large meeting of inhabitants passed a resolution the other day regretting the action of the Board of Trade in granting the British Electric Traction Company a 12 months' extension of time for constructing the light railway, and calling upon the Parish Council and the Rural District Council to convene a conference of local authorities with a view to arranging public ownership and control of the light railway, in order that there might not be any further delay in the construction of the lines.

London Tube Schemes.—The President of the Board of Trade states that new "tube" schemes or large railway extensions for the Metropolis must still be considered as subject to the warning given in the House of Lords that no enterprises of the kind can be considered by Parliament until the London Traffic Commission has issued its report. The President intimates, however, that exception might be made in urgent cases, and it is, of course, open to promoters to make application to Parliament in the usual way.

Pontypridd.—The Local Government Board have sanctioned the borrowing of £6,000 for a period not exceeding 30 years for the purchase of the tramway undertaking from the British Electric Traction Company. The clerk has been instructed to communicate with the company with a view to completing the purchase before the end of this month, and to ask for immediate possession. Eighty-six applications have been received for the appointment of resident engineer. The salary determined upon is £300 per annum. The Electricity Committee have selected certain candidates to appear before the Council.

Rochdale.—The Tramways Committee considered on Monday the further proposals submitted by Heywood, who desire either that the working expenses should be fixed at 4½d. per car mile for three years, or that Heywood should work their own cars, and be allowed to run into Rochdale. This was not agreeable to the committee, who object to any cars but their own running on their lines, and they also consider that 5d. per car mile for working expenses should be satisfactory, seeing that they have, in conjunction with Bury, offered to have a revision at the end of a year's time, should such be found necessary. Both Rochdale and Bury are agreeable to an entirely independent person going through the working cost for 12 months, and to be bound by the amount he should decide for the following five years.

Newport.—Colonel Druitt having inspected the Stow-hill route on behalf of the Board of Trade, the line was opened to the public on Saturday, a 10 minutes' service being provided. In the afternoon one of the cars got beyond the control of the motorman, and dashed down the hill at a great speed. There was a clear course, and, as the car kept the rails, the damage was trifling, being restricted to a slight bending of the trolley pole. There was a drizzling rain, and the motorman's supply of sand appears to have given out, with the result that the wheels were unable to effectively grip the slippery rails, thus diminishing the action of the brakes. Later in the afternoon a trolley wire fell at the Westgate centre, temporarily dislocating the service. Mr. Du Verge, the borough deputy electrical engineer, proceeded with the repair of the damaged wire, after which traffic was resumed.

Heywood.—At a meeting of the Tramways Committee on Monday it was decided to buy 10 steam-engines and cars so as to provide a service of trams within the borough. At a previous meeting it was decided to promote a Bill in Parliament during the coming session to deal with various matters in connection with the town. It is proposed to acquire powers to run trams along Middleton-road to the borough boundary, and to the borough boundary at Bamford, so that the committee will have the power, if it should be thought advisable in the future, to extend the tramway system in the directions named. Another suggestion is to include power to run into Bury and Rochdale. It was then stated that, failing an agreement with Bury and Rochdale, Heywood would be prepared to run their own cars into the adjoining towns, and give them power to run into Heywood.

Leeds.—As a means of finding work for the unemployed, a suggestion has been made locally that the scheme for making a tramway along Clarendon-road should be resuscitated. The Belle Vue-road scheme, which was substituted for this, leaves the whole of the Little Woodhouse district unprovided with tramway accommodation, and to the lack of this convenience the proposer attributes in a large measure the number of empty houses in the neighbourhood. The original scheme would probably need remodelling, and it is proposed that an extension should be made to the Ridge by way of Reservoir-street, Raglan-road, and Delph-lane, thus supplying direct communication between the centre of the city and a large and growing population on the Ridge, besides giving immediate access to one of our most beautiful public pleasure grounds. Such a route would seem to promise a good return.

St. Pancras.—The late mayor of St. Pancras (Mr. T. H. W. Idris), in his address to the Borough Council on the work of the past year, referred to the electrification of the tramways within the borough. He spoke of the negotiations with the London County Council respecting the employment of the overhead system, and endorsed the conclusion of the St. Pancras Council in favour of the conduit principle. He reiterated the view of the Borough Council that the obstacles in the way of the complete adoption of the conduit system through the borough were not insuperable. He also expressed the hope that all differences of opinion between the County Council and the Borough Council would be speedily settled, so that the public might be provided with an up-to-date tramway system at the earliest date. We fear that this hope is not likely to be realised in view of the action the County Council are taking in the matter.

Bournemouth.—For the six months ending Sept. 30 the tramways show a total of £7,385 as the excess of income over expenditure. During this period the tramways carried the population 95 times over. The future success of the undertaking will, of course, depend in a large measure upon the result of the recent arbitration proceedings with the Poole Tramways Company. The details of the six months' working show that the receipts aggregated £32,384, the working expenses £16,276, and capital charges £8,722. The passengers numbered 5,773,895. The revenue per car mile works out at 13d., the working expenses show 6·53 l. (generating expenses representing 1·37d. of this), and the net profit gives 2·97d. per car mile. It has been decided to acquire certain property in Southcote-road, and application is to be made to the Board of Trade for sanction to the borrowing of the purchase-money.

Wednesbury.—A local journal states that, although a certai amount of secrecy is being observed with regard to the tramway position, there are indications that the difficulties which have resulted in so much inconvenience to the travelling public, and have caused a complete stoppage of the service between Wednesbury and Darlaston for some months past, are on a fair way to being satisfactorily settled, if they have not even already been overcome. The attitude of the tramway company is said to point to a speedy restoration of the traffic between these two centres, as well as the opening up of traffic once more on the Dudley branch. A later announcement in the same paper indicates that a scheme for the electrification of the whole system will be undertaken forthwith, the directors having decided to put the contracts in hand. It is understood that the section from the White Horse, Wednesbury, to the Bull Stake, Darlaston, will be electrified first.

Aberdeen.—A rather curious position has arisen in regard to the work of effecting a junction between the Corporation lines in Bridge-street and Union-street. The Corporation obtained the sanction of the Board of Trade, but the Great North of Scotland Railway Company obtained an interim injunction from the Court of Session interdicting the scheme, on the ground of the proximity of the tramway lines to the Palace Hotel, of which the railway company are the proprietors. What objection the company had to the Corporation carrying the tramway lines to the company's hotel does not appear, but the Corporation appear to have clinched the matter by making the junction before the interdict arrived. For this purpose they utilised the slack period between Saturday night and Monday morning. The railway

Digitized by Google

company appear to be rather disconcerted by this promptitude, and criticise the "unseemly haste" of the Corporation. The matter will come before the Court of Session at Edinburgh in a few days for settlement.

Audenshaw.—At the meeting of the District Council, the Clerk reported with regard to the Audenshaw-road tramways, that it was necessary to apply to the Board of Trade for a further extension of time. He had prepared the requisite memorial, and all the notices for insertion of advertisements in the local newspapers. Since the tramways order was first granted in August, 1899, the time limit had been extended from time to time. The last extension granted would expire on Dec. 9, 1904. The Council had not commenced the construction of the tramways owing to the fact that the Great Central Railway Company proposed to reconstruct two bridges on their main line, and the work, in fact, was already commenced. The tramway would have to cross the main line by these bridges, and, in the opinion of the Council, it would not be expedient to commence the construction of the lines until such bridges had been reconstructed. Under these circumstances the Council asked for a further extension of time for a period of 12 months from Dec. 9, 1904. The Council resolved to seal the memorial.

Long-Lived Railway Motor.—Mr. James Anderson, manager of the Sandwich, Windsor, and Amherstbury Railway, Windsor, Ontario, some little time back reported a most remarkable life record of a Westinghouse 12-A railway motor under his charge. It has been in constant operation for a period of eight years, covering during that time a distance of approximately 450,000 miles, and beyond the replacement of brushes, remetalling of bearings, and turning-up of the commutator, has not cost a penny for repairs. The armature and field coils are intact, and the only signs of wear are on the commutator, which has been reduced ⅛in. by trueing up. The wearing depth of the segments is ⅜in., so that if the winding holds out, as there is every reason to expect it will, the motor should last another eight years and double its already remarkable mileage. We understand there are several other motors of the same type working on this line that hold very nearly the same record, and have been equally free from serious repairs. They are all operated in single equipment and under 18ft. cars, and as the load is practically level and without sharp curves, the conditions are somewhat favourable.

Yarmouth.—The Corporation have received a letter from the Board of Trade conveying approval of the service of a notice on the Yarmouth and Gorleston Tramways Company, Limited, requiring them to sell their undertaking. The Tramways Committee recommend that application be made to the Board of Trade for sanction to the form of construction of the tramways now worked by the Yarmouth and Gorleston Tramways Company, Limited, and the proposed additions, as authorised by the Great Yarmouth Corporation Act, 1904. The borough surveyor submitted specifications for tramway rails, fishplates, soleplates, tiebars, and bolts necessary for the proposed reconstruction of the tramways, and the committee recommend that these be approved. The following are the particulars of the receipts and passengers carried on the Corporation lines from the Sept. 30 to Oct. 27: 102,239 passengers were carried at 1d. fare, 479 at 2d. fare (these fares being discontinued after Oct. 6), 3,384 workpeople, and 697 scholars. The receipts amounted to £442. 3s. 3d. There is an increase on the aggregate return from April 1 to Oct. 27 of £549. 12s. 10d. compared with the previous year. The new Queen's-road line is showing a good return.

Brighton.—We have received the following particulars relating to the Corporation electric tramways for the year ending March 31 last from the tramways engineer, Mr. T. B. Holliday: single line, 1 mile 65·08 chains; double line, 8 miles 11·04 chains; total as single line, 18 miles 7·6 chains; maximum gradient, 1 in 10; sharpest curve, 40ft. radius; gauge, 3ft. 6in.; type of rail, 6in. girder; weight of rail, 101lb. per yard; rail laid on transverse steel sleepers and 6in. concrete bed; three boilers, Babcock and Wilcox, pressure 150lb.; three engines, Willans and Robinson, total horse-power 900; three dynamos, Bruce Peebles, total kilowatts 675; storage battery, 323 kw.; 50 double-deck, single-truck, 50-passenger cars; motors and controllers—30 Westinghouse, 10 Witting, Eborall, and Co., 10 Dick, Kerr, and Co.; contractors for permanent way, Macartney, McElroy, and Co., last extensions by Corporation's own staff; cables laid in Sykes's stoneware ducts; current return by rail; passengers carried, 10,999,046; car miles, 1,151,477; total receipts, £46,246. 3s. 10d.; total working expenses, £40,247. 4s. 2d.; gross profits, £6 016. 19s. 8d.; sinking fund and interest, £10,687. 7s. 5d.; deficit, £4,778. 16s. 4d; income per car mile, 9·6421.; expenditure, 8·412d.; average fare per passenger, 1d.; cost of power per unit, 1½d.; consumption of units per car mile, 1·54. The adverse balance is attributable to the low fares charged—viz., 2¼ miles for 1d. It has to be remembered also that 54 per cent. of the Brighton system is on a gradient averaging 1 in 17. The Corporation, we notice, have issued a complete diagram of the various routes, with full particulars of the services.

Llanelly.—At a meeting of the Urban District Council on Monday the report of the deputation that visited Cardiff on the electric light and traction question was given. This deputation met the engineer of the South Wales Power Company, Mr. Graham Harris, the manager of the Power Company, the managing director and solicitor of the British Insulated and Helsby Cables, Limited, and the secretary and managing director of the Llanelly Tramways Company. The interview was understood to be without prejudice. Mr. Harris informed the deputation that he was prepared to enter into an agreement with the Urban Council relative to taking over the liabilities and responsibilities of the Insulated and Helsby Cables, Limited, as to electric light and traction for Llanelly, but in a modified form. Further, the South Wales Power Company propose to apply to Parliament in the ensuing session for an extension of the powers of the Carmarthenshire Power Company to Llanelly in the event of Llanelly being willing that the parliamentary notice should contain such a proposal. He asked that a formal assurance should be given him that the Council were prepared, subject to a suitable agreement being entered into, to approve of the extension of the powers of the Carmarthenshire Company in the way referred to. A friendly discussion took place, and the deputation recommended that the clerk should be authorised to write to Mr. Graham Harris intimating that the Council will offer no objection to the inclusion of Llanelly within the area of supply of the Carmarthenshire Power Company, provided a suitable arrangement be come to between the parties. The chairman moved the adoption of the report, and another councillor, in seconding, referred to the pleasant nature of the interview. The proposition was adopted unanimously.

Paisley.—A meeting of the Tramways Committee was attended by Mr. Johnstone Smith, chairman of the Paisley Tramways Company, Limited. The provost having stated the various matters as to which the committee desired to meet with the representatives of the company, these being the question of children's fares, repair of George-street between Castle-street and Maxwellton-street, and completion of the undertaking so far as regards the extension to Greenock-road and Meiklerigge, Mr. Johnstone Smith stated, in regard to children's fares, his company were willing to substantially agree to the proposals of the Corporation. With reference to the repair of George-street, Mr. Smith stated that the company do not propose at present to proceed with the extensions to Meiklerigge and Greenock-road, but should the Corporation repair the portion of George-street referred to, he thought that the company would contribute a reasonable sum under this head if the construction of lines along that thoroughfare was decided upon. He also stated that, while there might be disappointment as to the company not proceeding at once with the extensions, it should be known that they have exceeded the original estimate as regards expenditure by having formed double lines where single lines only were contemplated. Furthermore, other extensions are in contemplation by the company. With regard to the congestion at certain parts of the route, Mr. Smith stated that if there is any proposal to remedy this by buying up and demolishing property in the neighbourhood, when this comes to be seriously contemplated and details are submitted, the company will be prepared to give every reasonable consideration to the matter. The official inspection of the Renfrew and Abbotsinch sections of the systems belonging to the Paisley and District Electric Tramways Company was made on Wednesday by Colonel von Donop on behalf of the Board of Trade. The inspection of these sections marks the completion of the extensive system of electric tramways inaugurated by Mr. W. M. Murphy on Nov. 2, 1903. The system connects Johnstone and Renfrew with Paisley, and from the Paisley Cross there are branches extending southwards to Charleston and Potterhill, and northwards to Abbotsinch on the Inchinnan road. Cars have been running over the whole system, with the exception of the Abbotsinch route, for some time. The inspection party included representatives of the Corporations of Paisley, Johnstone, and Renfrew. After carefully inspecting the equipment, Colonel von Donop expressed his approval. Subsequently the company entertained a large party, including several members of the Corporations, to lunch.

Wakefield.—The Wakefield and District Light Railway Company begun to run cars early in August, but no formal opening took place at the time, owing to the incompleteness of the system and other causes. This ceremony, however, was carried out on the 3rd inst., when members of all the councils over whose roads the lines pass were invited by the directors of the company to a general inspection of the system. The guests, some two or three hundred in number, assembled in the Market-place, Wakefield, where special cars were in readiness to convey them to Thwaite Gate, the terminus which connects with the Leeds Corporation tramways. The afternoon was somewhat chill and cloudy, but in spite of this the trip proved very enjoyable. On the return journey a halt was made at the Rothwell Haigh substation, which augments the power generated at the central station at Bell Isle, Wakefield. On arriving at the latter depôt, the party proceeded to inspect the car-sheds, the power-house, and the subsidiary arrangements for working the system. After light refreshments had been served, Mr. H. S. Leon (chairman of the board of directors), in welcoming the guests on behalf of the board, explained that the company had decided to take advantage of the visit to Wakefield of the Association of Tramway and Light Railway Officials to ask the members of the various local authorities to join them in an inspection of the system. The success of an undertaking of that kind, he proceeded, depended entirely on good management, and he imagined that they had as good a staff as it was possible to get. He took that occasion to acknowledge the excellent services rendered by the whole staff, from the chief officials to the conductors, under very difficult conditions. With regard to the local authorities represented by the guests, he hoped that the cordial relations which had existed in the past between those bodies and the company would be continued in the future. They recognised frankly that if they had been compelled to face the active opposition of those bodies, they would not have been able to open their lines at all. The advantages of a light railway of that kind had been perceived, and every assistance had been afforded the company in their work, and for this he desired to express the thanks of the directors. He could not say when the complete route would be finished, as in order to ensure financial success they would have to proceed cautiously, especially when it was considered that no less than £750,000 would be expended. The Mayor of Wakefield (Mr. E. Stonehouse) in proposing a vote of thanks to the directors for their hospitality, said that he hoped the system would prove successful and profitable. The Mayor of Ossett (Mr. F. L. Fothergill), in seconding the vote of thanks, remarked that the tramway was welcomed at Ossett, not only because it afforded better travelling facilities, but because it would extend building operations and thus increase the rateable value of land. He suggested that ½d. fares for short stages should be established. Mr. R. A. Smithson, chairman of the Leeds Corporation Tramways Com-

Digitized by Google

mittee, said that, on behalf of the municipality of Leeds, he had pleasure in wishing success to the undertaking of the Wakefield Company. He said that frankly, as one connected with municipal management, because there was ample room for private companies. He was glad that the company had set a good precedent by approaching the vexed question of running powers between municipal and private enterprises in what he considered was a broad-minded and sensible spirit. The propositions put before the Leeds Corporation by the company were of such a nature that the former body was very pleased to agree with them. Although he had not always done so, he ventured at this moment to back up the proposal for cheap fares, as they had found in Leeds that every concession made to the travelling public had resulted in increased profit. Mr. Leon briefly responded to the vote of thanks. Mr. H. England (general manager of the company), to whose admirable arrangements the enjoyment of the afternoon was mainly due, said that if the public would support the enterprise, the company would give as good a service as any in England. The recent reduction in the service was designed merely to ascertain the conditions under which they would have to work.

LIGHTING AND GENERAL.

Limerick.—The Corporation have concluded a loan of £7,000 for electric lighting purposes.

Little Lever.—The Urban District Council have applied for an electric lighting provisional order.

Surbiton.—The Urban District Council have applied for a provisional order to extend their district.

Armagh.—A special meeting is to be summoned three months hence to deal with the electric lighting question.

Hove.—The work in connection with the supplying of Aldrington with electricity will be commenced next week.

Battersea.—A new switch pillar is to be provided to replace the present pillar in St. John's-road at an estimated cost of £54. 9s.

Croydon.—An enquiry has been held into the application of the Corporation for sanction to borrow £29,765 for purposes of electric lighting.

Chertsey.—The opposition of the Urban District Council to the proposal of the Woking Electric Supply Company to extend its mains has been withdrawn.

Dover.—The Corporation propose to supply electric light and power to about a dozen villages near, and to extend their electric tramway system another two miles.

Cleethorpes.—The agreement between the Council and the tramways company governing the purchase by the Council of the electric power station has been sealed.

Llangollen.—The electric lighting installation was inaugurated last Friday by the directors of the recently-formed Llangollen and District Electric Light and Power Company.

Bedwellty.—The Guardians have decided to instal electric lighting plant in the workhouse at an expenditure of £2,000, Messrs. Lewis and Fletcher being the consulting engineers.

Agency.—The Rhodes Electrical Manufacturing Company, Limited, have appointed Mr. Vincent E. Walters, of 45, Newhall-street, Birmingham, as their sole agent for Birmingham and district.

Wirral.—The architect has submitted to the Guardians a report from the Liverpool and District Electric Lighting Company for providing an installation of 259 lights, estimated to cost £1,093.

Rhodes Electrical Manufacturing Co.—The directors have declared an interim dividend for the quarter ending Aug. 31, 1904, at the rate of 6 per cent. per annum on the ordinary shares of the company.

Bermondsey.—The Electric Lighting Committee are still deliberating upon the terms upon which to supply the Surrey Commercial Dock Company with current for power and lighting for a term of three years.

Sale of Plant.—Particulars of a sale of an entire electric installation, including 167 lots of fixed and unfixed electric fittings, magnificent cut-glass electroliers, etc., by Messrs. W. Dew and Son, Bangor, appear in another column.

Amazon Telegraph Co.—The accounts for the year to June 30 last show that after including £9,525 for debenture interest and sinking fund, the debit balance of £106,181 brought down has been increased to £113,311.

Fareham.—The Postmaster-General having heard that the alterations to the electric wires required by him would cost £55, has agreed to contribute £20 if the work was carried out satisfactorily to the Post Office and the engineer.

Scottish Steel.—At a meeting of Scottish steelmakers held on Nov. 8 it was resolved to reduce the price of ship-plates by 2s. 6d. a ton to £5. 12s. 6d., less 5 per cent.; but that of boiler plates and other material remains unchanged.

Stock Exchange.—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to Bath Electric Tramways, Limited, £135,000 4½ per cent. first mortgage debenture stock.

Stockton.—The Electricity Committee's last report shows that the cost of production for the September quarter, as compared with the cost in the corresponding quarter of 1903, has decreased about ¼d. per unit, the figures being 2·27d., as against 3·08d.

Fans.—The North British Station Hotel, Glasgow, is to be ventilated with electric fans, which are being supplied by Messrs. Matthews and Yates, of Cyclone Works, Swinton, Manchester, who have also supplied the fans for the company's hotel at Edinburgh.

Kensington.—Notices relative to proposed extension of their mains have been agreed to as follows: Kensington and Knightsbridge Electric Lighting Company—Kensington Court-place, St. Albans-road, and Glendower-place; Brompton and Kensington Electricity Supply Company—Pembroke-road and Philbeach-gardens.

Changes of Address.—We are informed that Messrs. Cowans Limited have removed their London office to 4, Queen Victoria-street, E.C., the telephone number being changed to "7,234 Central." The Key Engineering Company, Limited, have removed to the same address, the telephone number being identical.

West Bromwich.—It appears that the Corporation are still troubled with complaints against Alderman Pitt, chairman of the Electricity Committee, and the foreman fitter regarding unnecessary interference with the workmen. They have taken a lot of evidence, and a sub-committee has been appointed to report.

Spain.—The Government have authorised the Municipality of Mendoza y Rio IV. and the Executive Government of the Province of La Rioja to import certain specified electric lighting materials free of duty. The *Boletins* containing the announcements may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C.

Electricity Supply Co. for Spain.—The third drawing of 5 per cent. consolidated debentures for redemption at par on Jan. 2, 1905, will take place at the registered office of the company, College-hill-chambers, College-hill, London, E.C., on Nov. 21, at 11.30 a.m. The registered holders of these debentures, or their legal personal representatives, are entitled to attend at this drawing.

Lien Registered.—Otto Electrical Manufacturing Company, Limited—Issue on Oct. 21 of a £500 debenture, part of a series created Jan. 22, 1904, to secure £5,000, charged on the company's undertaking and property, present and future, including uncalled capital. Holder: J. Deakin, The Hall, Wormhill, near Buxton. No trustees. Total amount previously issued of same series, £2,000.

Humidifying Apparatus.—Messrs. Matthews and Yates, Limited, of Cyclone Works, Swinton, near Manchester, have just completed the erection of a humidifying and ventilating apparatus at Messrs. A. Barlow and Sons' Union Mill, Blackley, near Manchester, and we are informed that it is giving excellent results, both as regards the required amount of humidity and in keeping the CO_2 below the limit allowed by the Home Office.

Farnham.—The Urban District Council have consented to the application of the Farnham and District Electric Supply Company, Limited, for a provisional order empowering them to supply electricity within the urban district, subject to clauses being inserted for the protection of the Council's interests. The Council added a rider expressing the opinion that the works of the electric light company should be erected in the Urban Council's area.

Elland.—The output from the electricity works during September—3,825 units—shows an advance on the previous month's output by 1,204 units. The total units generated in September, however, was more than twice the output, being 8,265 units. The consumers number 77, and the 8 c.p. lamps connected total 4,542, whilst the total horse-power in motors is 61. The destructor in the month under review ran 240 hours, and destroyed 258 loads of refuse and 118 loads of sludge.

Hastings.—Certain low-tension mains and high-tension feeders are to be extended up to a transformer to be placed in a pit to be constructed under the public footway at an estimated cost of £100. With a view of obtaining an increase in the day load on the electricity plant by the supply of current for motors, etc., the Council have entered into an agreement with the Langdon-Davies Motor Company, Limited, of 101, Southwark-street, London, for the supply to consumers of alternating current motors on a hire-purchase system.

Cardiff.—The Lighting Committee have recommended the Council to apply for powers to borrow £87,000 for the extension of electrical plant, Mr. Arthur Ellis, the electrical engineer, having presented a report in favour of the extensions. At the present time there are applications for lighting and power equivalent to 46,000 lamps, and the orders cannot be carried out unless the plant is increased. The £87,000 will be spread over two years. The applications for power for motors are considerable and promise to keep the plant going in the daytime, so making the undertaking more remunerative.

Micanite Patents.—We are informed that the Supreme Court of Germany has by their judgment of Nov. 5, 1904, confirmed the validity of the German patent No. 73,830, the property of the Mica Insulator Company, Limited, of the Empire Works, Walthamstow, for the manufacture of micanite plates, and has dismissed, with costs, the appeal of Meirowsky and Co., of Cologne, for the withdrawal of this patent. This information will particularly interest those of our readers who may have observed that a few weeks ago the same company amended their English micanite patents No. 10,450 and No. 6,048.

Leicester.—The county architect reported at the last meeting of the County Council's Standing Committee that the Loughborough Corporation were prepared to supply the electric current to the Loughborough police court. The committee sanctioned the following expenditure: an electric motor, fan, and filter for the ventilating installation, at an estimated cost of £75; and electric pendants, brackets, and electroliers, at an estimated cost of £70. Mr. Pick was instructed to obtain tenders from Messrs. Ashwell and Nesbit and Messrs. Webb and Co., who have already carried out the ventilating and electrical lighting work.

Stretford.—The Electricity Committee have decided to supply current to a house in Upper Chorlton-road, Manchester, situate a few yards beyond the township boundary. The Manchester Corporation have agreed to allow the Council to supply current on the following conditions—viz., in the event of the Manchester Corporation deciding to lay mains along Upper Chorlton-road at some future time, the Stretford Council agree to allow the consumer to be transferred to the Corporation mains. In the event of the Manchester Corporation

Digitized by Google

deciding to lay mains in Upper Chorlton-road and taking over the supply in question, the Corporation would be prepared to bear the cost of the service which the Council proposed to lay.

New Issue.—Subscriptions are invited at par for £75 000 of 5 per cent. first mortgage "A" debenture stock of the Kalgoorlie Electric Tramways, Limited. The company was incorporated in 1902, with a capital of £250 000, divided into 250.000 shares of £1 each. The concessions owned by the company, the prospectus states, are as follows: (1) for the town of Kalgoorlie (constructed and running), 6½ miles; (2) for the Kalgoorlie Roads Board District (constructed and running), 8½ miles; (3) for Boulder City (constructed and running), 4 miles, and 1½ miles partly constructed. The remainder of the Boulder line is expected to be completed this month, and it is believed that the annual profits of the company will then amount to at least £20.000.

Gillingham.—The engineer in his last report states that the equivalent of 72 8-c.p. lamps had been connected since the last meeting of the committee, making a total of 11.969 8 c.p. lamps, with 210 consumers connected. An amended plan of the proposed lighting of Rock-avenue has been approved, also proposals of Messrs. Witting, Eborall, and Co., Limited, of Temple Bar House, London, E.C., for motors. With reference to the hire of radiators it was decided that the Council purchase radiators as required on the basis of £3. 1s. for a four-light radiator, to be let at a rent of 7s. 6d. per quarter. Sundry cable and plant is to be purchased from Messrs. W. T. Henley's Telegraph Works Company, Limited, for the sum of £274 at schedule prices.

East Barnet.—At the last Urban District Council meeting a member asked when the Council would be able, according to standing rules, to consider the desirability of rescinding the resolution as to proceeding with the electric lighting scheme of the National Construction Company, and was informed that the time limit would expire in six weeks, at the end of which time the Council could rescind the resolution if they thought fit. The clerk was instructed to inform the New Barnet Tradesmen's Association, etc., that consideration of the Construction Company's scheme had been for the present suspended. Finally a sub-committee was appointed to wait upon the North Metropolitan Company with a view to consulting as to the terms on which they would supply electric light in the district.

Kilmarnock.—The electric light supply was inaugurated on Saturday evening. Arrangements have been made to start the tramway cars on Dec. 10, when an inaugural ceremony will be performed by Lord Howard de Walden, the lord of the manor. Messrs. Kennedy and Jenkin, London, were the consulting engineers. Work has been most expeditiously carried out by the various contractors. The generating station has been erected at Riverbank, near Riccarton, and after the cars have commenced to run the station will be open one night per week to enable the public to inspect the premises and the machinery which has been installed. Mr. A. H. Burbidge, formerly with Messrs. Kennedy and Jenkin, superintended the construction of the works, and he has been appointed by the Town Council as resident engineer and tramway manager.

South Africa.—The *British and South African Export Gazette* says: "The electrical plant for the Aliwal North lighting scheme is now in course of delivery by the makers. It includes, besides the storage battery of the Hart Accumulator Company, Limited, already mentioned by us, a switchboard by Messrs. Crompton and Co., Limited, armoured cables by the British Insulated Wire Company, two 45-kw. dynamos by Messrs. Burstall and Monkhouse, and two 5-kw. boosters and a balancer by the Industrial Engineering Company. Nernst lamps by the New British Engineering Company, Limited, will be used. The Durban Municipality are about placing the following orders for material for their tramway system; 160 private consumers' meters of Messrs. Ferranti's make; 15 tramway feeder meters of Messrs. Chamberlain and Hookham's manufacture; 10 20-kw. Electric Construction Company's transformers and five street boxes for the same; and six miles of assorted cables. The concession for the electric lighting of Vryheid, Natal, has been granted by the Local Board to Mr. E. H. Godfery, Harrismith, Orange River Colony, who will shortly be placing orders for the necessary machinery and equipment. The tender of the Edison and Swan United Electric Light Company, Limited, for street electric light fittings has been accepted by the Johannesburg Municipality."

Wirt Dimmers.—On Tuesday last Messrs. Defries and Sons showed at their Houndsditch works some of the Wirt dimmers they have made to the order of Mr. Maskelyne for the production of the "Coming Race" at his new theatre. The novelty of the apparatus lies in the fact that the "resistances," which hitherto have been made in a large number of pieces connected together by separate joints and sometimes embedded in enamel, are constructed out of a single jointless ribbon of metal wound into as many coils as the number of graduations of brilliancy that are required (in the present case 50). Every turn of these coils is insulated with flake mica, and the whole series of them is arranged between mica discs which are encased between pressed steel plates by means of a single jointless band. The ribbon, which is in some cases as much as 50ft. long, is continuously tapered from end to end. The absence of joints, enamel, make the apparatus reliable and fireproof. This avoids not merely the risk of interruption to the performance, but also of fire, and it is a curious circumstance that of the entire equipment of the ill-fated Iroquois Theatre, Chicago, the only parts that remained uninjured were the Wirt dimmers, which are now operating in the new theatre. The Maskelyne installation includes 27 of these dimmers for the control of the fixed lights, in addition to others for regulating the movable arc lamps which illuminate special points.

Edmonton.—The District Council had before it on Tuesday night offers from the following firms for the execution and maintenance of electricity works under the Council's provisional order: North Metropolitan Electric Power Supply Company, Limited; Foot and Milne, Limited, Westminster; the Industrial Engineering Company, Newton Ironworks, near Hyde; and the National Electric Construction Company, Limited. The first-named company's proposals were based upon a scheme under which they would provide all the capital to be expended on the undertaking and work it, and refund the costs incurred by the Council in obtaining the order and the consulting engineer's fees, amounting to date to £2,800. The company did not propose to provide a separate generating station, but would give a supply from one of its existing power stations. It would agree to the undertaking being purchased at the expiration of 26 years or any subsequent period of seven years at a valuation. At the end of 26 years it was prepared to divide the net profits equally with the Council after it had had 5 per cent. upon the whole of the capital involved. The offers from the other three firms were based upon a scheme under which the Council would provide the capital to be expended. Foote and Milne, Limited, and the National Construction Company were each willing to maintain the undertaking for 25 years. They were prepared to have the agreement determined at the expiration of 15 years without the payment of compensation. The Industrial Engineering Company was prepared to maintain the undertaking for five years, the agreement to be determined at any time within that period upon the payment of such a sum as would bring up the profits to an amount equal to 3 per cent. per annum over and above the sinking fund and interest paid to the Council. After some discussion, the Council agreed to hold a special meeting to consider whether one of the tenders should be accepted, or whether a municipal undertaking should be established.

Bournemouth.—Mr. I. Bulfin, borough electrical engineer, in a recent report to the Tramways Committee on the working of the generating station for the six months ending Sept. 30, 1904, says: "During the period under review 869,227 Board of Trade units have been generated and distributed, being an increase of 112,305 Board of Trade units generated in the corresponding period of 1903. The working expenses for the above six months have been £3,788. 15s. 11d. The total works costs are 1·0461d. per unit generated, as against 1·1188d. for the year ending March 31. 1904, being a reduction of ·0727d. per unit, showing a saving of £263. 6s. 1d. on the units generated as compared with last year, this saving being mostly due to pumping from the artesian bore well during the last 3½ months, and thereby doing without the company's water. The estimated capital outlay on the station is £75,000, and allowing 6 per cent. for sinking fund and interest on this amount = £4,500 per annum, or £2,250 for the period in question = 6213d. per unit generated. The total costs, therefore, are: Total works costs, 1·0461d. per unit generated; interest and sinking fund, ·6213d. per unit generated; total costs, 1·6674d. per unit generated. The total cost per unit for the six months is, therefore, 1·6674d., as against 1·8058d. per unit for the year ending March 31, 1904, being a total reduction of ·1384d per unit generated. The Lighting Committee have taken 44,588 units at 2d. per unit, which has yielded a revenue of £371. 11s. 4d., which further reduces the cost per unit for traction purposes. During the above six months there has not been a single instance of failure to supply current to the line, and there has been a freedom from all breakdown, due chiefly to the care and attention of my assistant (Mr. F. Roose) and my shift engineers (Mr. H. M. Lawson and Mr. H. G. Andrews), and the whole of the staff of the generating station. The automatic cut-outs have acted 260 times, being a reduction of 50 per cent. on the corresponding period of last year. I would ask the committee to consider the advisability of putting the shift engineers on a sliding scale, at a commencing salary as now of £104 per annum, rising by yearly increments of £8 to a maximum of £120 per annum." The report was adopted by the Council at their last meeting.

Electrical Contracts.—Acting for the local engineers at West Hartlepool, Mr. E. Geipel, secretary to the Tees-side Association, wrote to the Electrical Lighting Committee of the Corporation referring to the pamphlet issued by the Corporation. Mr. Geipel says, *inter alia*: "A reference to Regulation No. 16 shows that where the consumer wishes the Corporation to carry out the work on the hire-purchase system it states: 'the Corporation will not undertake the wiring, but will invite tenders for the work from contractors'; see also Section (D), Regulation No. 12. To be assured that the work has been properly done, it is provided that it shall be tested by the borough electrical engineer, and notice that such a test is required should be given by the contractor as per Regulation No. 46. He then proceeds to formulate the following complaint—viz.: that a workman or workmen under the electrical department has or have worked for the Corporation during the day, for which they received their wages as agreed upon, and yet in the evenings have undertaken the carrying out of electrical wiring for consumers (which should have been left to contractors), and made their own charges. This, it is claimed, is an injustice to electrical engineers, who have had much to expend in their training, and now have showrooms, offices, rents, and rates, and taxes to keep up and meet; it is also unfair to their employés, who thus are deprived of labour by those who already have permanent employment by the municipality, and doubly so with the present depression in the borough. We have already suffered to an extent by the Corporation, under Regulation 12, providing motors 'on hire,' and trading in the sale of accessories—such as oil, carbon brushes, etc." In reply to the above, Mr. Higson Simpson, the town clerk, stated that it was not the practice of Corporation workmen to undertake electrical work for customers, and that the only work they had carried out had been at the request of customers to connect up short lengths of wire to meters. The Corporation quite agreed that it was not desirable that their workmen should, except in any such small matters referred to, undertake the work of wiring. The local electrical engineers are not satisfied with this explanation, and intend to bring the matter before Mr. Tweedy Smith, hon. solicitor to the National Association of Electrical Contractors.

Digitized by Google

Stourbridge.—The Building Committee's report at the last Guardians' meeting stated that according to an estimate from the architect the cost of wiring, fittings, etc., in connection with the electrical equipment of the workhouse would be £2,700. An electric generator would cost £4,270, and the cost for a unit of current from the local company would average 3½d. If the Board made its own electricity it would cost 2½d. per unit. Estimates were also given for the supply of gas. Much discussion took place, but no decision was arrived at.

Burgess Hill.—The General Purposes Committee's report submitted to the last Urban District Council meeting contained the following paragraph: "Correspondence was submitted from the Board of Trade with respect to the delay of the Council in the establishment of electric lighting works under the order granted to the Council and confirmed by Parliament in 1901. It was resolved to reply, stating that the Council had formulated a scheme and obtained tenders for the works. In consequence of the large amount of capital expenditure involved, and the present state of the money market, no further progress had been made in the matter, and, under these circumstances, the Council requested the Board of Trade to allow the provisional order to remain in force." The resolution for the acceptance of the proceedings was negatived.

London Gazette.—A receiving order has been made out in the estate of Alfred James Hollington, electrical engineer, 93, St. Martin's-lane, Charing Cross. The partnership between Walter Charles Bersey and Charles McRobie Turrell, carrying on business as consulting engineers at Dacre House, Arundel-street, Strand, under the style of Bersey and Turrell, has been dissolved by mutual consent. The partnership between Frederick Bridge and Sydney Mather Bewlay, carrying on business as electrical engineers, etc., at 12, Ryland-street, Birmingham, under the style of Bridge and Bewlay, has been dissolved by mutual consent. At an extraordinary general meeting of the members of the Sir Hiram Maxim Electrical and Engineering Company, Limited, it was resolved that the company be wound up voluntarily, and Mr. Alfred Hardie, of Wynstay, Cyprus-road, Finchley, N., was appointed liquidator.

St. Marylebone.—The last report of the Electric Supply Committee contains the following remarks on change of pressure: "We have now agreed the terms of the conditions upon which the London County Council are prepared to consent to the proposed change of pressure by the Borough Council, and expect shortly to receive from the County Council their approval to the proposed change. As the result of the advertisement inserted in September last in the papers prescribed by the London County Council, giving public notice of the intention of the Borough Council to apply to the London County Council for consent to the change of pressure, we have received three letters from consumers containing objections and enquiries as to the proposed change. The London County Council also received only three letters of objection. All of these have been satisfactorily answered by the electrical engineer." A number of applications from the Post Office authorities to lay pipes has been agreed to.

Bournemouth Telephones.—Two years ago the Town Council appointed a Telephone Committee to report on the desirability of establishing a municipal telephone system in Bournemouth. The principle of the scheme was affirmed at the Council meeting in October, and on Monday Alderman Lawson moved: "To rescind the resolution of the Council of Oct. 4 adopting the report of the Telephone Committee of Sept. 19, 1904." After a long discussion the motion to rescind was lost by 19 votes to 12. The Town Clerk said the National Telephone Company had written stating that, in view of the future extension of their system, it had occurred to them that the Corporation might secure a return on their capital expended in the laying of ducts in connection with their tramway system by letting them on rent to the company, which would at the same time minimise the disturbance of streets which would otherwise be necessary. They were prepared to meet the Corporation on reasonable terms.

Abergavenny.—At the last meeting of the Mon. County Council a report was presented as to the negotiations with the Abergavenny Corporation between the years 1891 and 1904 as to the price of gas for lighting the asylum, and also upon the advantages of lighting the asylum by electricity. It was estimated that the cost of electric installation and buildings would be £6,451, but that the annual saving in favour of lighting by electricity would be £67. Various tenders detailed in another column were accepted. It was stated that the cost of lighting in the past had been looked upon as a very serious item. There were 150 rooms in the institution that had up to the present never been lighted, and where it was impossible to put gas, while the electric light could be installed in those rooms with perfect safety. By electricity the Guardians would save the expense of painting so often, and, moreover, they would be meeting the wishes of their medical officer, who advocated electric light from a sanitary point of view.

Dublin.—Mr. Hammond has submitted an amended offer, which contains the following: "In view of my evidence at the recent Local Government Board enquiry in reference to decreased costs consequent upon the continued great progress of the new system, I am willing to make my offer even more favourable. I stated before the inspector that I estimated that an increased output of 320,000 units beyond the output named in my original report could be generated and distributed at 1¼d. per unit, and an increase of 880,000 units at 1d. per unit. Under these circumstances I beg to express my willingness, in the event of the Corporation giving me the supervision of the undertaking for seven years, to guarantee the Corporation the lower prices named in my evidence. I desire the special attention of the members of the Council to the fact that my proposal is to charge the Corporation not for units generated, but for units actually delivered to the consumers and to the public lighting circuits, and that when the output had reached 3,520,000 units the costs to the Corporation of generation and distribution would be as follows: output per my original report, which included the consumption by 500 public lamps, 2,645,000 units at 1¼d. per unit; output per my recent evidence, 880,000 units at 1d. per unit—total output, 3,525,000; average cost, 1·375d. per unit." On Monday's meeting of the City Council it was resolved to refer the consideration of the matter to a committee of the whole house.

Yarmouth.—The Electric Lighting Committee, in their last report, gives some particulars with regard to the proposed supply to Gorleston. It appears that the town clerk had asked the Port and Haven Commission whether, in the event of the Corporation deciding to take the cables under the water, the Commissioners would allow the cable to be turned up in their dolphin near the Gorleston Ferry, on the west side of the river, the construction on the east side of protection to the cable, 2ft. in advance of the quay face, and also if the Commissioners would forbid the dropping of anchors within 20 yards of the cables. The Commissioners then approved his plans and conditions, and resolved to forbid the dropping of anchors within 50 yards of the cable. Under the circumstances, the cost of the under-water system will be considerably reduced, and its safety be insured. The Local Government Board have already sanctioned a loan for £2,000 for this work, and £1,300 for storage battery and building. The committee state that if both systems were taken to Gorleston, the battery would not be required, reducing the cost under this head to £300, so that £1,000 capital expenditure would be saved. With favourable circumstances, the under-water work should be performed for the £2,000 sanctioned, but with the difficulties attending digging a trench 7ft. deep across the shifting bed of a strong tidal stream, it was impossible to say that the estimate would not be exceeded. The cables must be laid during the ensuing year, so that the matter might be ready for the electrification of the Gorleston trams. The Council have adopted the report, and the surveyor has been instructed to carry out the necessary work subject to further instructions being given by the committee with regard to the electric system to be adopted for the supply to Gorleston.

Colchester.—An enquiry has been held into an application of the Corporation for leave to borrow £16,500 for purposes of electric light extension. The electrical engineer, Mr. A. R. Sillar, explained the technical proposals. The loan is required partly for additional plant to meet the present increasing demand, and partly for other additional plant and further main extensions which would be needed within the next two or three years. The requirements for the ensuing winter include a new 550-h.p. engine, dynamo, and boiler, and necessary additions to the steam and exhaust pipes and other accessories, for all of which contracts have been entered into. For the succeeding period ending with the winter of 1906-7 it is anticipated that a 550-h.p. engine, dynamo, and boiler will be required, with also additional condensing and water-softening plant, and it was pointed out that if the contemplated main extensions were perfected, they would render the supply of current available to the urban portion of the borough and the greater portion of the suburbs. Statistics were given of the output of electricity, which, it was stated, had been for the year ended March 31 last 442,440 units, as against 265,310 for the previous year, being an increase of nearly 50 per cent. During the first three months of the running of the tramway system the output for that purpose had been 105,131 units. It was also stated that the capital expenditure per unit generated had at the end of 1903 decreased to half the expenditure on the first year's working, and it was anticipated that at the close of 1905 it would be reduced to about one-fourth of the original expenditure. From its commencement the undertaking had been financially successful, and the net profit on last year's working was £1,280, after allowing for every proper expenditure and deduction. No call in respect of the undertaking had ever been made on the rates, while, on the other hand, a sum of £500 had been placed to the credit of the general district rate out of the profit of £1,280, the remainder being carried to the reserve and renewal fund.

Cheltenham.—Mr. James Swinburne's report on the working of the electrical undertaking and as to its business and engineering management has been issued to the members of the Council. According to the *Birmingham Daily Post*, Mr. Swinburne points out that Cheltenham is peculiar in many ways. It is spread over a large area in proportion to its population. The private houses of the most well-to-do residents are generally in their own grounds, so that the customers otherwise most profitable are spread over a large area. The public street-lighting is also carried out in a more elaborate way than usual. Dealing in the first place with the accounts, he finds that depreciation should be charged in the case of a municipal undertaking, but that, other things being equal, it should be less than a private concern's depreciation by the amount of the repayment. In practice the case is much more complicated, by the borrowing of more money before the original loan is paid off, for necessary extensions of plant, etc. The obvious way of keeping matters straight, he thinks, is to pay off the first loan when taking up the second. But this method is not adopted, and so the capital accounts become a tangle of loans redeemable at different dates, at all sorts of rates of interest, and having no traceable relation to the plant actually in existence. At Cheltenham plant had been discarded, and the result is that the sinking fund was partly to pay off loans whose corresponding plant is not there. The real state is thus worse than the accounts alone can show, but only to a small extent. He makes the following suggestions as to the accounts: (1) That the interest and sinking fund should be charged as usual; (2) that a depreciation and antiquation fund on the present value of the plant, etc., at a percentage rate that would be charged in private concerns, less the percentage rate for the sinking fund, repairs, and other maintenance charges to come out of this fund; (3) that a rent should be charged for the works, such as the Council would have obtained had they let the ground; (4) properly speaking, the works should be charged with the same rates as they would have paid had they been a private concern. As regards distribution, the expert finds that the main cause of the

Digitized by Google

present position of the undertaking is that it has been managed too much with a view to a rosy future than a matter-of-fact present. As an instance, he says, the supply of energy was commenced about May, 1895, from works costing £16,800, but in July of the same year it was decided to apply for a loan of £10,000 for extension, and in February of the following year for a further loan of £15,000. It would have been more prudent to have accepted the view expressed in Mr. Hall's report until there were distinct indications that the undertaking would pay. Mains had been extended in a way which pointed to a complete absence of consideration of their really probable revenue. Expensive outlying consumers appear to have obtained the light on the same terms as those in the compulsory area. This must have been a source of loss. The result is that the system of mains in Cheltenham is a sort of skeleton, with very little on it. Dealing with public lighting, he points out that the 37 arc lamps in 1898 have been increased to 388 in the present year, and it appears to him that a town of 50,000 inhabitants can hardly afford to spend the £6,698 allocated to public lighting in the accounts of 1903 4, to say nothing of the larger sum of £8,610 necessary to make the undertaking pay expenses. From an engineering point of view the arc lighting is carried out satisfactorily. With regard to the price charged for energy supplied to the tramway (a private undertaking), the expert considers it is too low, and that it might be raised without approaching too nearly the cost of generating by the tramway company themselves. Apart from the question of policy in the rapid extension of mains and the installations of sub-stations to deal with a much larger future consumption, and of the policy in putting down so many arcs, Mr. Swinburne holds that the engineering has been carried out well and without extravagance, and a certain quantity of plant has been discarded for adequate reasons. With reference to the future, Mr. Swinburne suggests that a system of energetic house-to-house canvassing for customers be put in hand, and particularly in the streets which already have mains, so as to increase the revenue without a corresponding increase in the capital. As to street-lighting, the capital sunk in the arcs cannot be recovered, but in many of the streets the public would be satisfied with less light, and he recommends that Nernst lamps be put into the arc standards.

PROVISIONAL PATENTS, 1904.

Oct. 31.

23425. Improvements in live-rail protections for electric railways. James Linkleter, Tyneside Works, Tynemouth.

23438. Improvements in magneto-electric apparatus for ignition purposes in connection with internal-combustion engines. Henry Capel Lofft Holden, Gifford House, St. John's Park, Blackheath.

23452. Improvements relating to the insulation of coils of electrical apparatus. Odue Burdette Moore, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Nov. 21, 1903, being date of application in United States.) (Complete specification.)

23461. Improved portable electric alarm. Reginald Fox Rowe and William Roland Bloye, 17, Tetcott-road, King's-road, Chelsea.

Nov. 1.

23525. Improvements in connection with electrical radiators. Herbert John Dowsing, 115, Cannon-street, London.

23527. Improvements in or relating to electric cable conductors. William Ernest Hitch, 14, Abbey-road, Oxford.

23559. An appliance for diverging electric currents from a main line or for connecting cables or wires. Evaristo Garsin, 29, Mincing-lane, London. (Giovanni Bogni, Italy.)

23567. Improvements in and relating to electric incandescent lamps. Alfred William Hill and James Harrington, 22, Mazenod-avenue, West Hampstead, London.

23573. Improvements in or relating to driving belts and the like for preventing electrification of the same. Léon Leloup, Robert Obernesser, Jules Tenthorey, and Victor Tenthorey, 139, Queen Victoria-street, London.

23604. Improvements in or relating to electric incandescent lamps. Edwin Riethof and Anton Basch, 111, Hatton-garden, London. (Complete specification.)

23612. Improvements in enclosed dynamo-electric machines. Roger M. Newbold, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Nov. 3, 1903, being date of application in United States.) (Complete specification.)

23622. Improvements in galvanic batteries. Paul Möllmann, 6, Lord-street, Liverpool. (Complete specification.)

Nov. 2.

23661. Improvements in dynamo-electric machinery. Samuel Thompson Webster, 34, Castle-street, Liverpool.

23685. Improvements in electric projecting lamps, chiefly for enlarging and projecting lanterns. Leo Kamm, 27, Powell-street, Goswell-road, London.

23696. Improvements relating to electric cables or conductors applicable for submarine use. Joseph Arthur Lovel Dearlove, 7, Southampton-buildings, Chancery-lane, London.

23716. Improvements in devices for preventing sparking of the commutators of electric motors. Allgemeine Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Nov. 2, 1903, being date of application in Germany.) (Complete specification.)

Nov. 3.

23765. Improved insulating material for electro-technical purposes. Alexander Rudenick, 68, Alterwall, Hamburg, Germany.

23767. An electrically-operated protective or life-saving device for the fronts of tramcars and like vehicles. Alexander Milne, 26, Renfield-street, Glasgow.

23768. Improvement in electromagnets for extracting magnetic impurities from liquefied materials. Herbert William Wilson and the East Anglian Engineering Company, Limited, Stowmarket, Suffolk.

23769. Improved telephone system. Samuel Edward Barnes, 81, Bentley-street, Cleethorpes, Lincolnshire. (Complete specification.)

23797. Improvements in temperature compensating devices for electrical recording instruments. William Henry Bristol, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

23807. Improvements in trolley restorers. Edward Lewis Calahan, 70, Chancery-lane, London. (Date applied for under Patents Act, 1901, Nov. 6, 1903, being date of application in United States.) (Complete specification.)

23808. Improved construction of push-button switch. Arthur Charles Burnett and Joseph Richmond, 173, Fleet-street, London.

23811. Improved manufacture of plates and electrodes for electric accumulators and storage batteries. Georges Schauli and George Petrides, 173, Fleet-street, London.

23816. Improvements in electric control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23817. Improvements in electric motor control. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23820. Improvements in and relating to electrical choke coils. George Stevenson Carson, 77, Chancery-lane, London. (Date applied for under Patents Act, 1901, March 31, 1904, being date of application in United States.) (Complete specification.)

23823. Improved terminal for electrical apparatus. Henry George Pleated, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

23834. Improvements in or connected with alternating-current induction motors. Louis John Hunt and the Sandycroft Foundry Company, Limited, 6, Lord-street, Liverpool. (Complete specification.)

Nov. 4.

23857. Improvements in the construction of tramway trolley heads. Samuel Shepherd, jun., Bank-buildings, George-street, Sheffield.

23871. An electrical buoy light. Percy Watson, 117, Cleethorpe-road, Grimsby.

23899. Improvements relating to the manufacture of incandescent electric lamps. Alexander Just and Franz Hanaman, 7, Southampton-buildings, Chancery-lane, London.

Nov. 5.

23923 Improvements in incandescent electric lamps and in the method of exhausting the same. Alexander Wingate Kenyon, 9, Tempest Hey, Liverpool.

23932 Improvements in trolley wire supports. David Morton Paton, 65, Chancery-lane, London. Complete specification.)

23952. Improvements in and connected with telegraphic and other transmitting apparatus. James Tarbotton Armstrong and Axel Orling, 61, Chancery-lane, London.

23960. New illuminators applicable to electrical or other stage sights or for forming electric or other letters, signs, or the like illuminative displays. William Goulton, 114A, Chancery-lane, London.

23969. Improved construction of electric arc lamp. Hermann Diamant and Andrea Chiesa, 173, Fleet-street, London.

23971. A new or improved electric device adapted for circuit closing, indicating power transmitting, and possibly other purposes. George Lee Anders and Max Byng, Norfolk House, Norfolk-street, Strand, London.

23972. Improvements in electrical indicating or measuring instruments having springs to convey the current to a movable system. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske, Akt.-Ges., Germany.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Nov. 24, 1904.

1903.

23488. Electrical transmissions of energy through space. Artom. (Date applied for under International Convention, Sept. 12, 1903.)

23715. Apparatus for operating railway signals and points by electricity. Boddam.

23948. Electric tramcars. Conaty.

24023. Electric arc lamps or mercury vapour lamps or the like. Bastian.

24855. Memorandum and like appliances for use in connection with telephones and for other purposes. Gamble.

24129. Structure of alternators. Zani.

24144. Electrically-controlled valves. Junggren. (Date applied for under International Convention, Nov. 15, 1902.)

25020. Means for automatically governing electric motors, especially applicable for breaking or reducing the current in electric motor vehicles when a given speed of such vehicle is exceeded. Staunton.

25074. Electrical demand or rebate indicators. Case and Reason Manufacturing Company, Limited.

25858. Windings for dynamo-electric machines. British Thomson-Houston Company Limited. (General Electric Company.)

26427. Electromagnetic controlling gear for electric arc lamps, electric circuit breakers, and the like automatic mechanism. Eckstein and Angold.

27722. Alternating-current induction motors. Hunt and Sandycroft Foundry Company, Limited.

28030. Electric meters. Rimington.

28032. Metallic conduits for electric light cables and the like. Waterhouse and Simplex Steel Conduit Company, Limited.

1904.

1364. Gas or vapour electric apparatus. Le Tall. (Cooper-Hewitt Electric Company.)

1609. Means for adjustably suspending electric lamps and other articles. Napier-Clavering.

2458. Brush-holders for dynamo-electric machines. Acly. (Date applied for under International Convention, Jan. 31, 1903.)

2839. Incandescent electric lighting appliances, more especially adapted for use in theatres. Schwabe.

2865. Printing telegraph receivers. White.

4918. Automatic circuit breaking safety appliances for use in trolley wire systems for electric traction. Carter, Hall, and Parsons.

8378. Arrangement whereby ordinary house electric bells can be used for electro-medical purposes. Page.

9215. Electric switches for electric chronographic or time-recording devices. Wilson. (Date applied for under International Convention, April 21, 1903.)

11405. Automatic electric switch for the intermittent lighting of electric lamps or groups of lamps. Pounsford and Love.

12615. Thermo-electric piles. Katz.

13489. Process of and apparatus for the electrical separation of granular material. Schnelle. (Date applied for under International Convention, June 15, 1903.)

14568. Arrangement of electric cables working with high voltage. Siemens-Schuckert Werke G. m. b. H. (Date applied for under International Convention, June 29, 1903.

15551. Prevention of fires caused by short-circuits or by injury to electric conducting wires or cables. Wilhelmi.

16509. Directories or indicators for telephones. Drowns. (Date applied for under International Convention, Jan. 29, 1904.)

17166. Gas or vapour electric apparatus for use as lamps and for other purposes. Flichtner. (Date applied for under International Convention, Aug. 10, 1903.)

18322. System of electric lighting for railway trains. Pieper and L'Hoest.

18383. Indicating device for electrical fire-alarms. Hoenicke.

18827. Electric temperature signalling device. Klopfenstein and Klopfenstein.

18908. Electric time-recording mechanism and apparatus. Kelly.

19334. Electrically-driven fans. Reiss and Klemm. (Date applied for under International Convention, Oct. 12, 1903.)

19585. Magnetic compasses. Herrick. (Date applied for under International Convention, Sept. 12, 1903.)

20134. Controlling apparatus for electric motors for working lifts and like apparatus. Klinkenberg.

NOTES.

Faraday House.—Prof. C. A. Carus-Wilson, M.A., M.I.E.E., yesterday commenced a special course of lectures to the senior students of this institution upon direct-current motor construction.

Corps of Electrical Engineers (R.V.).—The annual dinner of the corps is to be held at the Criterion to-morrow evening at 7.30, when the members will doubtless muster in full force. Inadvertently we stated the date in our last issue as being the 12th.

Royal Statistical Society. — At the inaugural meeting of the present session of the Royal Statistical Society on Tuesday, Sir Francis S. Powell, the president, presented the Guy medal to Mr. D. A. Thomas for his paper on "The Growth and Direction of our Foreign Trade in Coal."

Northampton Institute.—The Right Hon. Lord Reay, G.C.S.I., G.C.I.E., LL.D., will distribute the prizes at the Northampton Institute for the session 1903-4 on Friday, Dec. 9, at eight o'clock. The prize distribution will be followed by a conversazione, which will be continued on the following day.

New Paper.—The Faraday Society having decided to issue their own *Proceedings* in future, the publishers of the *Electro-Chemist and Metallurgist* propose to issue only one more number of that journal under its present title, but they hope to bring the paper out upon an enlarged scale in January next under the title of *Metals* (with which will be incorporated the *Electro-Chemist and Metallurgist*).

Metric System.—Our readers will remember that at their opening meeting of the session the Rugby Engineering Society held a discussion on the advantages of a metric system as compared with the present system of weights and measures in force in this country. After the discussion a vote of the meeting was taken, and the society passed its opinion in favour of the introduction of the metric system. In the resolution by which this decision was arrived at the opinion was expressed that the advantages of the metric system to mechanical and electrical engineers are so great as to outweigh the temporary inconvenience caused by the transition period.

Glasgow Section.—The third annual dinner of the Glasgow Section of the Institution of Electrical Engineers was held in the banqueting hall of the Grosvenor Restaurant, Glasgow, the function being presided over by the chairman of the Local Section, Mr. R. Robertson. There was a numerous gathering of electrical engineers belonging to Glasgow, London, and other places, a large contingent of the civic dignitaries, and a number of Pressmen. The banquet proved highly successful, and Mr. E. G. Tidd, the local hon. secretary, wound up the speeches by declaring that if the members wished to support him in his work, the best way was to come forward with papers and participate in the discussions. The parent institution was represented by Mr. R. K. Gray and Mr. G. C. Lloyd, the secretary.

Thermal Storage.—This system of storing energy in heated water has not come so rapidly to the front as was expected five or six years ago. We are pleased to see, however, that the electrical engineer to the metropolitan borough of Hammersmith (Mr. G. G. Bell) has advised his committee to employ the system in connection with their new boiler plant. In this case four storage vessels, each capable of holding 50 tons of water, will be employed, and will be used to store heated feed water throughout the day. This hot feed water will then be passed into the boilers at night, with advantages which will be apparent to all steam engineers. The thermal-storage equipment, which will be capable of holding 200 tons of hot feed water at boiler pressure, will cost only £2,616, and we agree with Mr. Bell that this is a reasonable price for the advantages secured.

Some Physical Properties of Current-Bearing Matter.—An article on this subject by Mr. Paul R. Heyl appears in the October number of the American *Physical Review*. The contribution is supplementary to a descriptive *résumé* in the *Journal* of the Franklin Institute for March of the work that has been done in determining the physical properties of current-bearing matter. It may be stated at once that the results presented are negative. The experiments show that any change in the tensile strength of iron for a current density of 2,000 amperes per square centimetre cannot exceed one-half of 1 per cent., and for copper with a current density of 1,000 amperes per square centimetre the alteration cannot exceed one-fifth of 1 per cent. Any change in the melting point of tin for a current density of about 2,500 amperes per square centimetre can hardly exceed 2deg. There is some reason to believe that a more powerful method would definitely show a small rise in the melting point.

Personal.—We hear that Mr. W. B. Esson, after occupying the post of chief engineer and manager to leading electrical firms for the past 20 years, during which period he has been responsible for the carrying out of a large number of important schemes, has commenced practice as a consulting engineer at 1, Victoria-street, Westminster, where his extensive experience will be available for all matters connected with electrical undertakings. We also learn that Mr. J. Gordon Wilson, who for many years has been connected with Messrs. Siemens Bros. and Co., has now resigned his position of chief electrical designer to the firm, and has started consulting engineering work in Edinburgh. Mr. Wilson has entered into partnership with Mr. Norman A. Thompson, who lately occupied the post of manager and resident engineer to the Clyde Valley Electrical Power Company, and the firm of Messrs. Thompson and Wilson will have their offices at 22, North Bridge-street, Edinburgh.

Manchester Section.—This branch of the Institution of Electrical Engineers will open its session at the Grand Hotel, Manchester, to-night at 7.30, when Mr. C. D. Taite, the chairman, will deliver his inaugural address. On the conclusion of this a smoking concert is to be held. The programme for the session is as follows: Nov. 29, "Compensated Alternating-Current Generators," by Mr. M. Walker; Dec. 13, "High-Tension Switchgear," by Mr. L. Andrews; Jan. 17, "Electric Driving in Textile Factories," by Mr. H. W. Wilson; Jan. 31, "Some Points on the Selection of Electric Cables," by Messrs. L. B. Atkinson and C. J. Beaver; Feb. 14, "Manchester Tramways Power Supply," by Messrs. S. L. Pearce and H. C. Gunton; Feb. 28, "Mechanical Construction of Steam-Turbines," by Mr. W. J. A. London; March 3, annual dinner; March 14, "Low-Tension Thermal Cut-outs," by Prof. Schwartz and Mr. W. H. N. James; March 28, "Use of Electrical Energy in Mines and Collieries," by Mr. M. B. Mountain; and April 11, general meeting. As in previous years, the general meetings will be held at the physical laboratory, Owen's College, by permission of the authorities. The Students' Section has also arranged a number of meetings to be held at the municipal school of technology, and visits will be paid to several neighbouring works.

Egyptian Business.—The complaint has frequently been made in consular reports that English firms are not sufficiently keen in securing reliable representatives abroad.

Digitized by Google

It will be remembered that in our last week's issue Mr. R. A. Dawbarn made the same remark with respect to South Africa, where, he said, the representatives of English firms left much to be desired. News has just come to hand of the commencement of a combined agency in Egypt which has much to recommend it. The companies concerned are five in number, and their businesses are such that they do not compete one against the other. These five firms have floated a company with a capital of between £20,000 and £30,000 under the title of the British Engineering Company of Egypt, Limited. The firms interested are Messrs. Dick, Kerr, and Co., Callender's Cable and Construction Company, Limited, Messrs. Babcock and Wilcox, Limited, Messrs. Gwynnes, Limited, and Messrs. J. Gibb and Co. Offices worthy of the firms interested are being erected at Alexandria, and we have no doubt that the combination will tend not only to the good of these firms, but will also greatly assist in the development of engineering work in Egypt. The advantage of having actually on the spot a first-class staff able to deal with any class of engineering business is one which cannot be over-estimated, and considerations of economy would prevent each firm from keeping a separate expert staff. We trust that this form of co-operation will be extended to the Colonies.

Educational Reform.—The multiplicity of examinations for entrance into the professions is engaging the attention of the Board of Education. It is proposed to bring these tests of knowledge into close connection with the work of each school. A committee has considered the whole question, and suggests that a general system of school certificates should be instituted and given on examinations—including an oral examination in modern languages—controlled by a university, a combination of universities, or an examination board representative of a university or universities, and of the local authorities which are prepared to co-operate with them, together with representatives of the teachers, and that a central board should be established for England, consisting of representative of the Board of Education and of the different examining bodies, whose duties it should be to co-ordinate and control the standards of examination, and secure the interchangeability of certificates. This central board, it is suggested, should be constituted by the Board of Education as soon as a sufficient number of recognised examining bodies have signified their willingness to be represented thereupon. It is proposed that the certificates shall be of two kinds—a junior certificate, limited to pupils under 16 years of age who have received not less than three years' instruction in a school accepted for examination, and a senior certificate for pupils who have received not less than four years' tuition. The London County Council's Education Committee has expressed its approval of this movement, which, it is to be hoped, will result in the present too numerous examinations being reduced to one or two on a more systematic basis.

Thermo-Electromotive Force.—A paper on this subject was read by Mr. C. B. Thwing before the American Physical Society, and an abstract of the paper appears in the *Physical Review* of New York. The author remarks that on the hypothesis that an electric current in a metal consists of a displacement of negative corpuscles, it might be expected to follow that the direction, as well as the magnitude of the pressure tending to produce such a flow in a metallic circuit due to unequal temperatures at two points in the circuit, would depend upon the rates of expansion of the metal at the two temperatures. The coefficient of expansion of many metals, and of a number of alloys having high thermo-electric force, was determined both between 20deg. and 60deg. and between 60deg. and 100deg. with a good degree of accuracy, and the thermo-electric force of the same specimens was determined over about the same range of temperature. Comparing the rate of increase of coefficient of expansion from 40deg. to 80deg. with that of lead, the thermo-electric power of which is reckoned at null, it was found: (1) That for nickel and bismuth and for nickel alloys having, like these metals, a negative E.M.F. the rate of increase of expansion is negative and numerically larger for the metals having a high E.M.F. (2) That for metals and alloys like antimony and its alloys having a positive E M.F. the rate of increase of expansion is positive and numerically larger for the metals having a high E.M.F. (3) That for alloys of Ni-Cu, Sb-Zn, and Sb-Cd, all of which have an E.M.F. much higher than either constituent, the coefficient of expansion is abnormally low as compared with the value computed from those of the constituents, the value in the case of one of the Sb-Cd alloys being but one-third of the calculated value. These remarks harmonise with the hypothesis referred to above.

The Rhodes Scholarships.—At the Hôtel Métropole last week Dr. G. R. Parkin delivered an address to the members of the Royal Colonial Institute upon the Rhodes scholarships. The speaker paid a high tribute to the imperial aspirations of Cecil Rhodes. Admitting that the Colossus made at least one grave error of judgment in political morals, Dr. Parkin considers that when his environment in the early mining town life of South Africa is remembered, our wonder must be that he adhered so consistently to noble conceptions of the use of wealth. Dr. Parkin feels emboldened to assert that in Cecil Rhodes we had "a man whose mind moved on a larger constructive line for the good of his fellow-men than any other Englishman of our time." Having alluded to the services Rhodes rendered to the Empire in South Africa, including the Cape-to-Cairo Railway, the speaker detailed the history of Rhodes's scheme for welding the Anglo-Saxon race—the creation of the Rhodes scholarships. Dr. Parkin humorously describes the fluttering in the Oxford dovecotes when the bequest was announced. "The fact," he remarks, "of 200 young men being drawn to her from the ends of the earth—from South African veldt and Western prairie, from New Zealand bush and Rocky Mountains—awakened visions of untamed cowboys and boundary riders, of bowie-knives and revolvers, invading the High-street — rather trying to the imagination of cloistered scholars"! But the feeling was transient, and Oxford as a whole welcomed the larger opening. The contingent of Yale students who recently entered into residence on the Isis have awakened the admiration of university educationists by the seriousness with which they devote themselves to research. Dr. Parkin, it may be mentioned, was privileged to assist in the arrangements for carrying out the trust, and his account of its organisation is deeply interesting. Wherever Dr. Parkin has been in the Colonies the potentialities of the scheme as a mighty binding force have been freely recognised, and in the United States he has found the idealism of Mr. Rhodes accepted as a truly noble one. The speaker concluded by enlarging upon the advantages of the trust in enabling students from abroad to obtain a wider knowledge of the affairs of the universe.

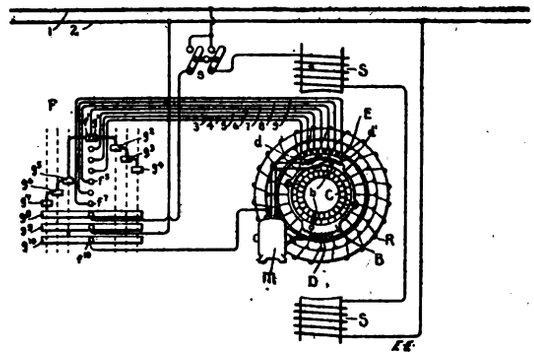
New Patent Regulations.—The new patent regulations, which come into force on Jan. 1, have just been issued, and Messrs. W. P. Thompson and Co., patent agents, whose remarks on this subject we published a few weeks ago, direct further attention to the leading provisions. If the invention is found to be described or claimed in some

Digitized by Google

one or more British patents published during the immediately preceding 50 years, the attention of the inventor will be directed to the fact, and he will be required to cut out the old matter within two months of the date of the official letter, or to acknowledge in his patent that he is aware of the prior patents. This acknowledgment must take the form of an insertion after the claims in the specification as follows: "Reference has been directed, in pursuance of Section 1, Sub-Section 6, of the Patents Acts, 1902, to the following specification of letters patent (giving the name and number)." If the description in the specification is not sufficiently clear, the inventor may be required to amend or amplify it, but if he do so, it is within the comptroller's discretion to date the patent as of a date subsequent to the original date of the application, but not later than the date when the amendment was made. The decision of the Patent Office officials is subject to appeal to the comptroller, followed, if necessary, by appeal to the law officer. If the applicant, having passed the examination process, desires to have a patent sealed on his application, he must on or before the last day on which the patent can be lawfully sealed pay an additional fee of £1. It is important to remember that, under these new rules, provisional protection will be granted for only six months instead of nine months, as hitherto. Under the new system several distinct matters cannot be deemed part of one invention simply because they relate to an existing machine, apparatus, or process, and the work of searching will thus be kept within reasonable limits on each application. These regulations may be an improvement on the present system, but they leave a lot to be desired, for even if the examiner approves an application, and a patent is granted, its validity is not assured. In this connection the words of the President of the Institution of Electrical Engineers at last week's meeting are of considerable interest. A report of same will be found in another column, and, as Mr. Siemens points out, an elaborate system of preliminary examination, such as is practised in the United States, which still leaves the inventor open to a lawsuit, is delusive. The new regulations have been hailed in some quarters as an important reform, but we fear the inventor's millennium is not yet.

The Institution.—In the presence of a very large meeting the 1904-5 session of the Institution was inaugurated yesterday week. After the formal business had been concluded Sir William Preece proposed a vote of thanks to the retiring president, Mr. R. K. Gray. Sir William eulogised Mr. Gray's great services to the Institution, and spoke, after an acquaintance extending over 30 years, in glowing terms of his personality and generosity. The admirable manner in which Mr. Gray had lately conducted the party of members through the United States was dwelt upon by Sir William in enthusiastic terms. Prof. S. P. Thompson, in seconding, referred to Mr. Gray's invaluable efforts when the Institution lost the services of the late Mr. McMillan. "His devotion to the Institution during that emergency," said Prof. Thompson, "could never have been exaggerated." He had served as the Institution's figure-head during the visit to Northern Italy, and only just recently he had piloted a large party around the United States. "We, indeed, owe a great debt," concluded Prof. Thompson, "to our past-president, whose tenure of office has been marked by unique events." The new president, Mr. Alexander Siemens, in conveying to Mr. Gray the vote of thanks, which was accorded amid great enthusiasm, said, "As your immediate successor, I regret you have given me an example which it will be hopeless to attempt to follow." Mr. Gray feelingly acknowledged in brief terms the kind manner in which his services had been appreciated, and expressed his thanks for the great assistance he had received from the Council and the staff. Mr. Siemens then delivered his inaugural address, part of which we published last week, the remainder appearing in this issue. Colonel Crompton proposed a vote of thanks to the new president for his highly interesting, if somewhat controversial, paper. Mr. J. E. Kingsbury, in seconding, remarked that whilst the paper might be controversial in some respects, he thought the points dealt with were of vital importance to the profession. He had given them some instructive information in regard to the metric system, and the advice in regard to British industries given in the concluding lines was most valuable. Mr. Siemens, in acknowledging the vote of thanks, said he was very sorry he had been unable to exclude controversial matter, but he thought the subjects, and particularly the metric system, were of great importance. In concluding the proceedings, Mr. Siemens announced that he had been invited, as president of the Institution, to attend the twenty-fifth anniversary of the establishment of the German Institution. This will be celebrated on the 25th inst.

Distant-Control Apparatus.—A device for the distant control of machinery electrically has been patented in the United States by Mr. M. R. Hanna, who has assigned it to the General Electric Company. The *Western Electrician*, of Chicago, gives the following description of the operation of this device in controlling the brush position of motors on a car or train; but the invention can also be used for a number of other applications. In the accompanying diagram S represents the field or stator of a motor connected through the switch, *s*, and the line-wires, 1 and 2. The rotor, R, is provided with a commutator, C, on which the brushes, *b*, bear. Brush-holder ring, B, has gear teeth cut on its lower side, and these teeth are engaged by the worm, D, driven by pilot motor, M.



Thus, as motor, M, revolves, B will be rotated in one direction or the other, depending upon the direction of rotation of motor, M, and the brushes, *b*, will be shifted. Brush-holder ring, B, carries two movable contacts, *d* and d^1, which are secured to ring, B, but insulated therefrom and from each other. These movable contacts engage the segments of the stationary commutator, E, which is secured to the frame of the machine. The segments of stationary commutator, E, are connected through the conductors, 3 to 9, to the controlling switch, F. Controlling switch, F, comprises 10 stationary fingers, f^1 to f^{10}, and 10 movable contacts, g^1 to g^{10}. With the controller in the position shown, and with switch, *s*, closed, there is no tendency for the motor, M, to rotate. It will be seen by the diagram that the current from motor, M, is flowing in parallel through the two leads connected to *d* and d^1. The motor is so arranged that when the current is flowing through both of these leads there is no tendency for the motor to rotate. Now, if controlling switch, F, is moved in one direction or the other—as, for instance, towards the left, until contact finger

Digitized by Google

f^2 engages contact g^2—it will be seen that the circuit through movable contact d^1, through the controller, F, has been shifted from contact finger f^1 to contact finger f^2, and consequently from conductor 6 to conductor 5. Movable contact d is in engagement with the commutator segment to which conductor 5 is connected, consequently current will flow from the motor through movable contact d alone. The motor will revolve, rotating brush-holder ring, B, in a counter-clockwise direction, and will continue to revolve until movable contact, d^1, makes contact with the segment to which conductor 5 is connected. Movable contacts, d and d^1, being thereupon brought into contact with the same segment, current again flows through the two in parallel, and the motor ceases to rotate. As controller, F, is shifted to another position the same operation is repeated. Thus it will be seen that each position of the controller corresponds to a certain position of the motor brushes, and by simply moving the controller to any one of its positions, motor, M, will automatically bring the brushes of the large motor to the proper position, and will then stop. Furthermore, it is evident that the brush-shifting devices and pilot motors for any number of main motors may be connected to a single controlling switch, F. The brush position of any number of motors may be controlled from a single point. The inventor has designed pilot motors for use in this device both for direct and alternating currents.

Tramways and Light Railways Association.—By permission of the London County Council, Mr. A. L. C. Fell, the Council's chief tramway officer, piloted a party of members on Friday last around the Greenwich power station and the New Cross and Clapham sub-stations and car-sheds. At present the structures, and particularly the power station, are of more immediate interest to builders than to electrical engineers, though considerable progress has been made. At the present time one-half only of the power station is being erected. The delivery of the bulk of the plant is expected early next year, and the portion of the station now in course of construction will probably be at work by the end of that year. The boiler-house and engine-house are parallel with each other, and when the whole station has been completed will measure 440ft. by 80ft. each. The boiler-house will contain 48 water-tube boilers on the ground floor, arranged in two rows, with four chimneys, each 14ft. internal diameter and 250ft. high. Each boiler will be fitted with superheaters, and will evaporate 16,300lb. of water per hour, at a pressure of 200lb. per square inch. Chain-grate stokers will be used. Immediately over the boilers is an economiser floor on each side of the boiler-house. Large steel coal bunkers are being erected above the economiser floor, and will deliver coal to the furnaces of the boilers by means of chutes. The storage capacity provided in the completed station is 10,000 tons. The engine-room will contain eight vertical-horizontal engines of 6,500 h.p. each, and each engine will have mounted on its shaft a three-phase generator of 3,750 kw. capacity. Four of these combined sets are being erected at present. The type of engine is a new one for this country, and it possesses several important features, as each engine is, in reality, two complete compound engines, with the vertical high-pressure cylinder and the horizontal low-pressure cylinder on each side of the generator. There are only two main bearings for the shafts, and the cranks are overhung. The vertical and horizontal connecting rods, on each side, work on the same crank pin. Separate steam inlets and condensers are provided for each half engine, so that in case of emergency one half can be run without the other by removing the connecting rods. As the cranks are set 135deg. apart, eight distinct steam impulses are obtained per revolution, resulting in a very even turning movement, so even that an independent flywheel is not required. The drainage of the engines is perfectly natural, as the low-pressure cylinder is horizontal. Each engine will carry on its shaft, between the cylinders, a three-phase generator as mentioned above. The output of each machine will be 350 amperes per phase at 6,600 volts between phases, and 25 cycles per second. The speed will be 94 revolutions per minute. In addition to the main engine sets, two auxiliary steam-driven sets are being provided, each of 250 h.p., and these will be used as a stand-by for the excitation of the large machines as well as for partly lighting the station. Separate exciters for each generator have been provided to avoid complication in the switchgear. The supply of water for the condensing plant in the basement of the engine-room will be provided by centrifugal pumps in a separate pump-house. The pumps will be driven by three-phase motors, and will draw their water from the Thames through 30in. pipes. All the auxiliary plant will be electrically driven. At present the Council's operating charges amount to 7d. per car mile, which Mr. Fell hopes will be reduced to less than 6d. when the Greenwich station is available. When the New Cross car-shed is finished it will have accommodation for 295 cars. The sub-station, which operates the lines within the radius of about two miles, is equipped at present with three 300-kw. synchronous motor-generators, and there is room for two others. The alternating-current side is operated at 6,600 volts, three-phase, and 25 cycles per second, and the direct-current side gives an output of 550 volts. The speed of each set is 300 revolutions per minute. The Clapham sub-station contains at present only a low-tension distribution switchboard. When the main station has been completed, this sub-station will be equipped with machinery and switchgear similar to the other sub-stations.

Electrical Typefoundry.—A large printing plant has recently been opened by the American Typefounders' Company at Communipaw, New Jersey, in which electricity is employed throughout for power and lighting. A description of the installation appears in the *American Electrician*. The general lay-out is such that extensive additions may be made should future occasion require it, but at present the power generating plant is capable of furnishing all the power needed both for motors and electric lighting. It is installed at a point on the shop grounds about 200ft. north of the main group of buildings, and from here electric current and steam are delivered to the various buildings through conductors and pipes located in a covered trench. The boiler equipment consists of two 150-h.p. Heine water-tube boilers, which are equipped with "Tread-kill" rocking grates and with improved Argand blowers. The feed-water pumps deliver through a 500-h.p. Cochrane feed-water heater, and thence to the boilers. The connections provided in the feed-water system are very flexibly arranged. There are three pumps, one of which may be used as a fire-pump. They are located conveniently for access in the open space in the boiler-room between the boilers and the engine-room partition. The feed-water heater is located to the left of the pumps. The generating equipment consists of three direct-connected units. Two of the engines are tandem compound of 125 h.p. each, the other is a 60-h.p. Woodbury engine. An automatic oiling system is provided, and the engine cylinders are provided with shifting valves and are drilled and tapped for indicator connections. The engines are operated non-condensing, and are provided with the usual centrifugal flywheel governor. The generators are all of C. & C. make, two being of 75 kw. capacity and the other of 30 kw. capacity. They are compound-wound machines,

Digitized by Google

and generate an E.M.F. of 125 volts. A gauge board is provided on the wall of the engine-room, containing two high-pressure steam-gauges, a low-pressure steam-gauge, a recording steam-gauge, and a clock. The switchboard is 19ft. long and stands 8½ft. high, the panels being of a uniform height of 7½ft. and surmounted with an ornamental copper grill. The arrangement of the panels from left to right is as follows: one 5ft. distributing panel, three 3ft. generator panels, and one 5ft. storage battery panel. The distribution panel has 12 pilot lamps in a double row across the top, four 50-ampere circuit breakers, three 400-ampere circuit breakers, one 150-ampere circuit breaker, four 800-ampere circuit breakers, and one 1,000-ampere double-pole switch for connecting the street service should this become necessary. In the centre of the panel there is a voltmeter of the double-reading type, serving also as a ground detector. It is controlled by a push-button switch. The three generator panels are all equipped alike. Each panel has a pilot lamp, Empire voltmeter and ammeter, Thomson integrating wattmeter, field rheostat, plug for parallel connection, one 750-ampere double-pole switch, one 750-ampere single-pole switch, and one 750-ampere circuit breaker. The storage battery panel has three pilot lamps, Empire voltmeter and double-reading ammeter, one 150-ampere battery circuit breaker, one 30-ampere circuit breaker for the booster motor, one Bristol recording voltmeter with a 25-ampere double-throw switch, one 25-ampere circuit breaker, one 200-ampere double-pole main switch for battery charge and discharge, one 100-ampere motor switch, and a 10-point end-cell switch. A swinging differential voltmeter is mounted on a bracket on the left end of the board, and is used for coupling the generators in parallel. All of the instruments excepting the recording meters are set in the back of the board, and have dials illuminated by incandescent lamps from the rear. The general electrical distribution is on the two-wire system at 125 volts. All of the motors, and also the lamps, both arc and incandescent, are supplied with current from the same 'bus bars in the power plant. The distances from the switchboard to the various points of current consumption are not great, so that even with the maximum distance the E.M.F. generated is sufficiently economical. Only a few arc lamps are used, and these are of the enclosed type. The greater part of the illumination is by incandescent lamps. The type-casting machines are equipped with Stow multi-speed motors, built by the Stow Manufacturing Company, of Binghampton, N.Y. The motors are back geared, and the speed is varied through a wide range by the rheostat and the method used in the Stow motors of changing the magnetic reluctance of the field. The plant is reported to have given entire satisfaction.

Transposition of Electrical Conductors.—At a recent meeting of the American Institute of Electrical Engineers Mr. F. F. Fowle presented a paper on this subject, of which an abstract appears in the *Electrical Review* of New York. The author commenced by distinguishing between alternating-current systems for the transmission of power and intelligence respectively. Whereas the former are characterised by high power, large currents, low or moderate frequencies, and only one fundamental frequency, telephone systems are characterised by low pressure, small currents, and high frequencies, available over a large range. He then considered the electric and magnetic fields set up surrounding conductors, showing that where there are not more than three circuits, each consisting of a pair of wires, it is possible to place them so that there will be no mutual interference; but when the number exceeds three, it becomes practically impossible to prevent this. Discussing the transposition of conductors as a means of eliminating these disturbances, the author enumerated the further conditions necessary to dispose of the disturbances. The current in the disturbing circuit must be constant in magnitude and in phase throughout the distance *l*, as illustrated in Fig. 1, and the pressure must likewise be constant in magnitude and in phase. That is, 1 must be so short a portion of the wave-length in the disturbing circuit that these conditions are sensibly fulfilled. At low frequencies the wave-length is not the primary consideration, but rather the drop in line pressure and the decrease of the line current, due respectively to wire impedance and to the leakage and the static charge. The induced currents due to electric induction

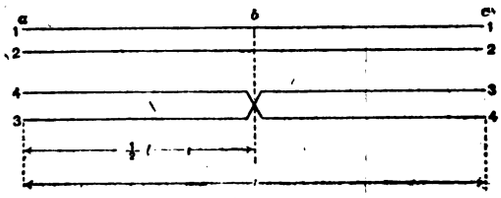


FIG. 1.

cannot, unlike those due to magnetic induction, be made to vanish entirely. The treatment of induction between telephone circuits has been by empirical rule rather than theory It has been determined by experiment with receivers of a given sensitiveness and transmitters of a given power, how frequently two adjacent circuits should be transposed in order to eliminate the cross-talk. Using two-mile sections, transposed at the centre, the cross-talk is distinguishable with transmission sufficiently powerful for 1,000-mile service. Half or quarter-mile sections, transposed at the centre, are satisfactory; this results in a minimum transposition spacing of one-quarter mile. The existence of cable at each end of the line in any considerable length will reduce the cross-talk. It is necessary to devise different types of transposed circuits, no two transposed alike, in order to treat the cases occurring in practice.

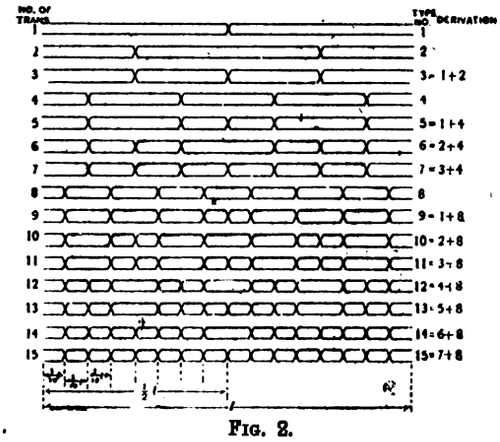

FIG. 2.

The manner of doing this is shown in Fig. 2. The "exposure" of circuit 1 to circuit 2 is one-fourth; of 1 to 3 is one-fourth; of 2 to 3 is one-half; because a transposition at the junction of two sections, each transposed at its centre, has almost no beneficial effect. The exposure of 1 to 5 is one-eighth; of 2 to 6 and 3 to 7, one-eighth; of 2 to 8 and 2 to 9, one-sixteenth; and so on. The derivation of the types is simple; the first three are obvious. The fourth is obtained by doubling the number of divisions of the transposition section from two to four, etc. The choice of a convenient length for *l* is an important matter. An eight-mile section has been extensively used, but is probably too cumbersome. A much more convenient section would be one four miles in length. If there are only a few circuits, a two-mile section may be used.

NOTES ON MOTOR-STARTING SWITCHES.

[CONTRIBUTED.]

(Continued from page 625.)

The necessary operations for the successful working of a reversible motor can be attained either by mechanical or electrical means. A simple form of the mechanical method is shown in Fig. 8. This illustrates a starting switch made by Messrs. Royce, Limited. It will be seen from the figure that the pulley is mounted on a shaft to which is affixed a weight. This is so balanced that the slightest movement

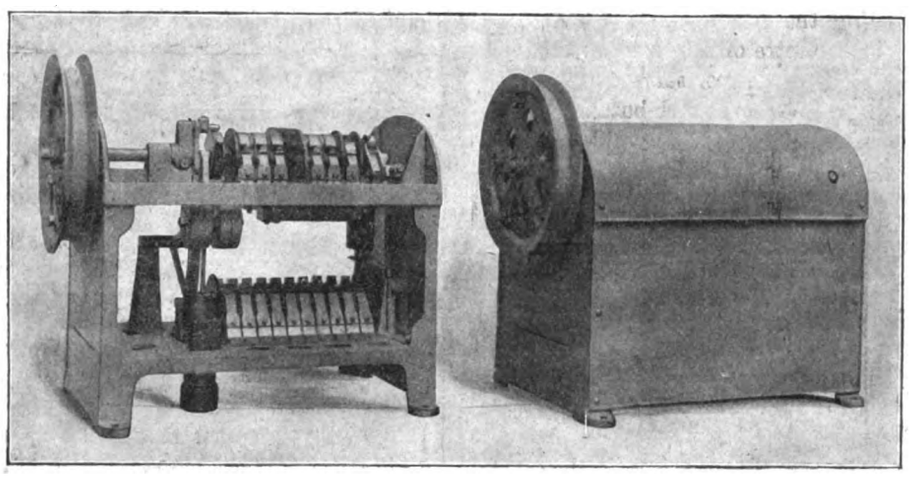

FIG. 8.

in either direction will cause the weight to fall over on one side of the shaft. This causes the shaft to revolve, the speed being regulated by teeth gearing, and as the shaft revolves the resistance is cut out of the armature circuit. The speed of the motor can be further controlled by pulling the rope to a greater extent and so inserting resistance in the shunt circuit.

The Sturtevant Company, Limited, make an elaborate type of electrically-controlled switch, which is shown in Figs. 9 and 10. The rheostat contacts are mounted on one side and the reversing switch on the other. This switch is

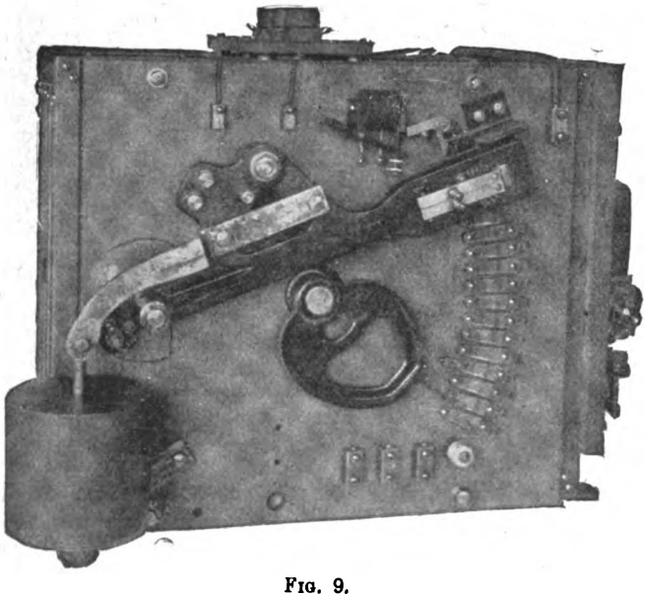

FIG. 9.

designed on the same lines as the self-starting switches. A grooved pulley is mounted on the extended shaft, and the operating rope, which passes through the cage, is passed round and secured to this pulley, so that if the rope is pulled down the reversing switch is turned in the direction necessary to drive the cage downwards, and if pulled upwards, the reversing switch will be turned in the direction to propel the car upwards also.

The function of the reversing switch is to set the direction of the rotation of the motor, and also to open and close the main solenoid switch circuit. This circuit never carries more than about half an ampere, and as it never directly makes or breaks the motor circuit, the sparking is reduced to a minimum. When the reversing switch is brought into the "off" position, it turns the cam, which is mounted on the opposite end of the same shaft in such a direction as to force the rheostat contact lever into its highest position, with the result that all the resistance is inserted into the motor circuit, and in which position it is held by a small detent. When the reversing switch is brought into the "on" position in either direction, the cam on the rheostat front is moved into a position in which the contact lever is free to fall to the lowest position if released by the detent. The solenoid circuit of the main switch is at the same time excited, with the result that it attracts its plunger and closes the main circuit, thereby supplying current to the motor armature through all the rheostat resistance. This main current passes through a small electromagnet on the upper part of the rheostat front, and trips the detent which was holding the contact lever up, consequently the contact lever falls by gravity at the speed to which the dashpot has been

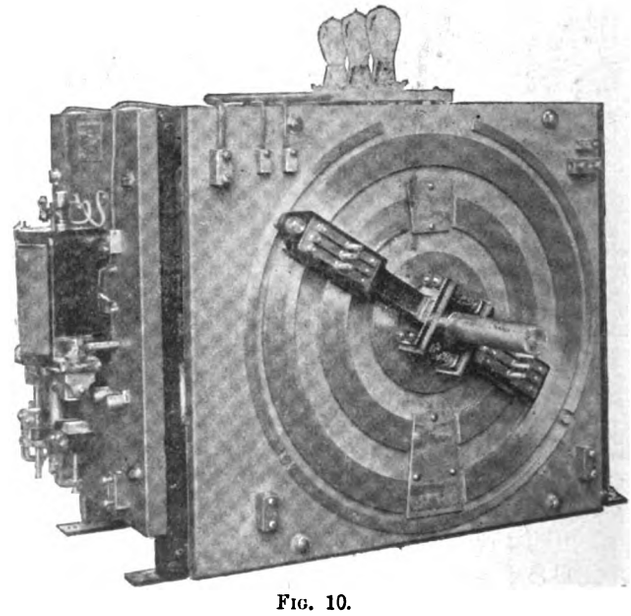

FIG. 10.

previously adjusted, and so slowly cuts out the rheostat resistance, and brings the motor up gradually and easily to its proper speed.

One main point is that the motor circuit is always made and broken by the solenoid controlled main switch, which is equipped with large carbon contacts for making and breaking the circuit, and also with blow-out magnets for preventing arcing. The solenoid main switch and the rheostat contact lever are electrically interlinked in such a manner that the solenoid main switch will not close except when all the rheostat resistance is in series with motor armature. This

Digitized by Google

means that in sudden reversal it is impossible under any circumstance to reverse the current through the armature until the motor is at rest. It will be noted that lamps or other high resistance are inserted to absorb the self-induced current of the shunt when this circuit is broken, while in addition, after the solenoid has performed its lifting effort, its current consumption is reduced to a negligible amount by the automatic insertion of a high resistance in series with its exciting coil.

An extension of this arrangement is also supplied, if necessary, in this case. No ropes are employed, but a car switch (illustrated in Fig. 11) is placed in the cage, and the whole apparatus is operated by means of this switch, which opens all the circuits when the handle is in its central position, and causes the cage to either ascend or descend as the handle is moved to the right or the left. This car switch does not handle the main current required for the motor, but the whole apparatus depending for its successful working on the closing and opening of various solenoid switches, all the car switch has to handle is the small currents required for energising these solenoids.

The movement of the car switch from its central position first excites two out of four solenoids, causing them to close their switches, and so determines the direction of rotation of the motor. After this has been so determined, the solenoid main switch closes and supplies current to the motor through all the rheostat resistances, while at the same moment the brake solenoid is excited, causing it to release the magnetic brake. An additional solenoid, known as the accelerating solenoid, is then energised and pulls up the contact lever at the speed to which the dash-pot has been adjusted previously, thereby slowly bringing the motor up to its normal speed by gradually cutting out the resistance. Should the attendant forget to stop the cage at the extreme limits of the travel the circuit will be automatically opened by the limit switch, and the cage brought to a standstill in precisely the same way as when it is stopped by the attendant. The same arrangements are adopted of interlinking the main switch and the rheostat contact lever as in the former case, so that there is no danger of the motor being reversed too suddenly, and the same precautions are taken of automatically inserting a high resistance in the solenoid circuit, and also to absorb the self-induced current of the shunt when this circuit is broken.

(To be continued.)

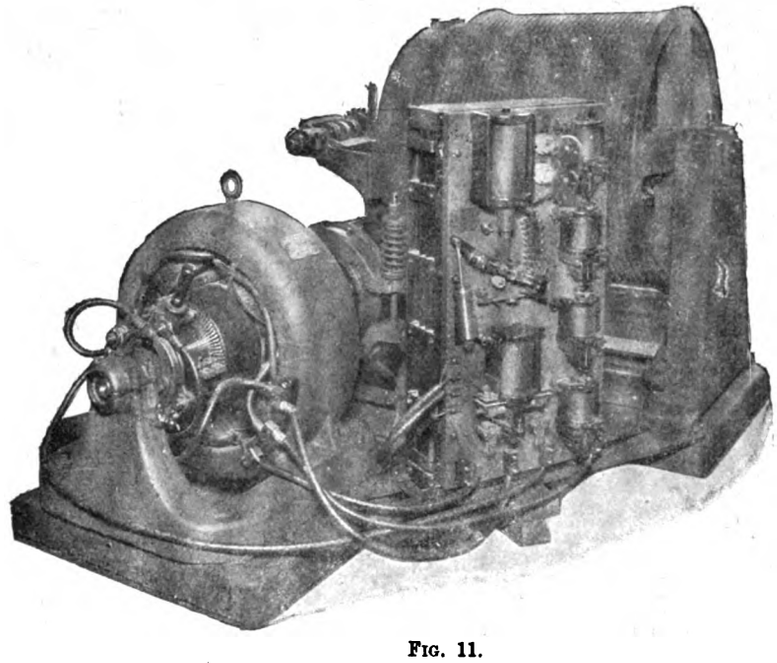

FIG. 11.

TEST ON 500-KW. CURTIS TURBINE SET AT CORK.

In view of the great interest taken by engineers in the performance of steam-turbines, we think that the publication of a series of tests carried out on a 500-kw. continuous-current Curtis steam-turbine set at the Cork Electric Tramway and Lighting Company's station, and which was supplied by the British Thomson-Houston Company, Limited, of Rugby, may be of interest.

These tests were conducted by Mr. Charles H. Merz, the consulting engineer to the company, by whose courtesy we are enabled to publish the results obtained. The object of the tests was to ascertain the steam consumption at varying loads, and for this purpose five tests were made—at quarter load, half load, three-quarter load, full load, and 25 per cent. overload respectively. The tests were generally of 1½ hours' duration, although the last test, at 25 per cent. overload, was slightly under one hour. Great care was taken in each case that before the test was commenced all conditions of load, etc., should be absolutely steady.

The weight of condensed steam was measured by a tank and weighbridge, which was tested before and after the test and found to be accurate. Vacuum gauges were connected to the low-pressure chamber of the turbine and to the body of the condenser. These gauges were in agreement. Under conditions of full load, however, the vacuum registered in the turbine exhaust chamber was 2in. lower than that registered in the condenser, showing that the pipe connection from the turbine to the condenser was not sufficiently large. The barometric pressure throughout the test was 30·16in.

The output of the machine was measured by two ammeters, a standard voltmeter, and a recording watt-

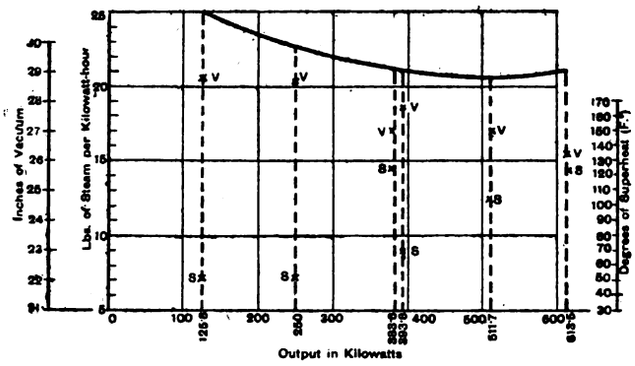
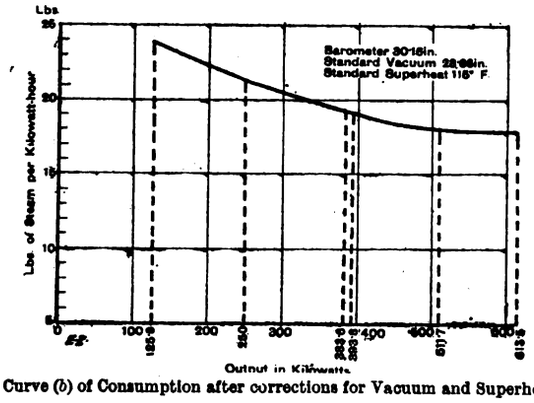
meter. The figures entered on the log-sheet attached are the mean figures of all readings at each load, readings being taken every six minutes. The readings given are the corrected mean readings after each instrument had been carefully recalibrated against a standard in the Newcastle-upon-Tyne Electric Supply Company's test-house.

The tests were started by taking a reading of the wattmeter and by commencing to fill the water-tank, and three minutes after the start ammeter and wattmeter readings were taken. Six minutes after the first wattmeter reading



Curve (*a*) of actual Consumption of Steam with 500-kw. Curtis Turbines. Barometer 30·16in.

a second wattmeter reading was taken, and the condensed steam was weighed. Six minutes after the first ammeter and voltmeter readings second readings of *these* instruments were taken, and so on. Hence all readings were taken every six minutes, the ammeter and voltmeter readings midway between the wattmeter and condensed steam records.



Curve (*b*) of Consumption after corrections for Vacuum and Superheat.

A general summary of the results of the tests is given by the log-sheet attached. Steam consumption curves are also attached: (*a*) curve actually obtained; (*b*) curve made out with correction to 26·66 vacuum and 115deg. superheat.

INSTITUTION OF ELECTRICAL ENGINEERS.

Inaugural Address.

BY ALEXANDER SIEMENS, PRESIDENT.

(Concluded from page 707.)

However important capital and labour are to an industry, the third factor, "management," is none the less essential for its satisfactory progress. Under this term everything is included which appertains to: (*a*) the selection of site for works, their planning and their equipment; (*b*) the commercial work connected with the business; (*c*) the arrangements for carrying on operations; (*d*) the designing of new apparatus and the investigation of new methods of manufacture. It is easy to understand that in every one of these directions good management can do much to lower the cost of production, but this is hardly the time to discuss all these points in detail. Only on the last I venture to make a few remarks, as the proper design is a matter in which the members of this Institution are interested, more particularly those who have only recently graduated from a college. A good design should have for its aim the lowering of the cost by employing simple component parts which can either easily be obtained or cheaply manufactured. The first requirement is fulfilled by utilising standard sizes, and in this respect the work of the Engineering Standards Committee is of the greatest possible importance to the industries of this country. In addition to these "public standards," much can be done to facilitate work by adhering to standard parts in each factory, so that it is not necessary to carry an immense variety of parts in stock.

A number of graduates do not realise that the object of their working practically in the various shops, in addition to studying at a college, is to teach them by their experience what the difficulties of the various operations really consist of. It is not so important that they learn to overcome these difficulties as easily and as quickly as a skilled workman, but that they acquire the habit of thinking how to avoid these difficulties when they are designing new work, and how to take advantage of the material at their disposal. In other words, a designer should have an intimate acquaintance with the scientific principles that come into play and with the ways in which they are applied, and he should know, if possible from personal experience, the capabilities and the limitations of the workman and of the machinery by which the operations are carried out. It is, however, by no means sufficient for preparing suitable designs to be well acquainted with the means employed to execute them; it is just as important to form an accurate conception of the problem that has to be solved, and to possess a thorough knowledge of previous attempts in the same direction, and of the causes of their success or failure.

Another branch of knowledge required for the good management of factories is a careful training in the way of conducting experimental investigations, coupled with the good judgment as to which investigations are worth taking up. No doubt the list of qualities that ought to be found in a good manager could be extended still further, but enough has been said about all the three principal factors to show the great number of different points which have to be considered in connection with the internal working of modern industries. Besides these internal factors, there are all the external circumstances which influence the well-being of the industries, and it is easy to see, even without entering at length into further details, that no true picture of the state of an industry can be arrived at if only a few features of their complicated constitution are to be taken into consideration.

These remarks about industries in general apply naturally to the young electrical industry quite as much as to the oldest-established one; there are, however, some features of its development which have greatly contributed to its rapid rise, and could, perhaps, be imitated in other industries to their great advantage. At first the long time during which weak battery currents alone were employed, chiefly for telegraphic purposes, permitted the completion of important scientific investigations, which in the end led to the discovery of those fundamental laws which form the basis of all practical applications of electricity. Nor has science deserted the industry when it began to deal with powerful currents. I will only remind you of Dr. John Hopkinson's mathematical demonstration in this room, that alternate-current machines can be worked in parallel. This example is particularly interesting, as in this case science has pointed out to the engineer how he could solve one of his problems. Usually the function of science has been to prevent its followers from being deceived by appearances or by plausible fallacies. By such negative indications alone science can give definite answers, while its deductions of a positive character cannot be accepted without further proof, owing to the uncertainty whether all premises necessary for the correct solution of the problem have been taken into consideration. For this reason deductions arrived at theoretically should be tested by practical applications before further conclusions are based upon them. Here again the electrical industry has had the great advantage of possessing from its very beginning most sensitive instruments, which, in addition, are easily handled, so that the verification of theories has been a comparatively easy matter, and it has been possible to control by accurate

Digitized by Google

measurements all operations not only in the laboratory, but also in the workshop.

One feature of electrical measurements has contributed more than anything else to the rapid rise of the industry, and that is the adoption of the same units of measurement in all countries. The idea of such a system originated with Prof. Wilhelm Weber, of Göttingen, about 70 years ago, but the British Association for the Advancement of Science has the honour of having taken the first step to realise the proposal of Weber by appointing a committee to suggest practical electrical units. This committee, after due deliberation, chose as the basis of their system the centimetre, the gramme, and the second, and I should like to know why they chose the metrical units, unless they had convinced themselves that these were the best for the purpose. At that time (1861) there was no question of international units, nor had the metrical system been adopted as universally as it is now; all the more weight ought, therefore, to be attached to the decision of this committee, which consisted of eminent scientific men and prominent engineers, so that both the theoretical and the practical aspects of the question were kept in view during their deliberations. Certainly there is no doubt about the beneficial effect of the adoption of this system by all countries, and I have no recollection of ever hearing that the decimal division adopted in it has given rise to any difficulties. It is true some modifications have become necessary, which were discussed and accepted at a series of international congresses called for the purpose, but so far as I am aware nobody has ever suggested that it would be to the advantage of any country to start a system of electrical units of its own. In spite of this favourable experience, we all know that there exists still an obstinate resistance against the general introduction of the metrical system into this country, although it has been shown over and over again that the reasons advanced for this obstruction are based on fallacies, and are opposed to the experience of other countries. Such an attitude is very largely due to want of practice with a thoroughly consistent system of weights and measures.

In this connection it is significant that all engineers who have had to deal for any length of time with metrical measurements unhesitatingly prefer them to the English want-of-system. I am, of course, aware that some prominent engineers profess to have tried to work with metrical units, and have been unable to work as quickly and easily with them as they could with their accustomed units. About them one is tempted to say that their conclusion in this particular matter is about as reliable as that of a man who tries to skate, and, after his first attempt, gives it as his opinion that you cannot move faster by skating than by walking. Another big outcry is raised against the metrical system on account of the great disturbance of all business transactions that would result from the change of weights and measures, and appalling figures are marshalled as to the expense of giving effect to it. It does not appear that other countries have been ruined by discarding obsolete weights and measures, nor should the expert opinion of the inspectors of weights and measures be ignored, who unanimously consider the introduction of the metrical system to be a pressing need to put an end to the existing confusion, and advocate, in addition, that such an introduction should be made compulsory.

The very same thing has been recommended by two or three parliamentary committees after hearing innumerable witnesses for and against the change. Why should such well-considered opinions be calmly ignored, and why should the bogie of expense be trotted out before the public when the real sentiments of the opponents about the disturbance of trade, caused by a change of weights and measures, are disclosed by the fact that they themselves advocate a revised British system, based on the inch, the introduction of which would have the same disturbing influence as that of the metrical system, but would lack the advantage of making the international metrical system the universal one? For it cannot be doubted that the example of Great Britain would immediately be followed by the British Colonies and by the United States, so that the whole community in all civilised countries would enjoy the same advantages as the electrical engineers already possess. Against this argument the opponents of the metrical system usually point out that even in France some instances can be found where the old measures are used in preference to the metrical ones, but on examination it turns out that only the old names are preserved in some districts and in some trades, but that in reality the measures in use are based upon metrical units.

The few exceptions are only proving the rule; and it would be as wrong to say that the metrical system is not universally used in France or Germany, as it would be to contend that English is not the language of the United Kingdom, because you can find people in some remote parts who do not know that language.

As a last resort the expense of changing the screw-threads is urged against the change to the metrical system, and the Continental practice of calling the system "Whitworth thread" is considered an incontrovertible proof that the metrical screw-thread is impracticable. If all taps and dies and leading screws had to be exchanged at once, it would certainly be a costly affair, but such a measure is not likely to be adopted, as no advantage could result from it. For the real difficulty with screw-threads is that giving dimensions on paper is not sufficient to ensure that the screws, manufactured according to such instructions in different works, are really interchangeable. This subject has been investigated by a committee of the War Office, and their conclusions throw a very interesting light on the controversy. In their opinion it is only possible to obtain interchangeable screws if the leading screws by which they are made have all been cut on the same screw-cutting lathe, or are at least cut on benches which are fitted with a leading screw manufactured on the original bench. If another link is interposed, differences in the screw turned out become perceptible. As a consequence of the finding of this committee a screw-cutting lathe has been set up at the National Physical Laboratory, where leading screws for screw-cutting lathes are to be manufactured. The same experience has been made in other countries where nominally "Whitworth's threads" are used. It is not possible to make screws interchangeable by prescribing their dimensions; the only way is to obtain taps and dies or leading spindles cut by the same tools. If it is not a case of extreme accuracy, there is no difficulty in cutting English threads by means of a metrical leading screw or *vice versâ*. By using a wheel with 127 teeth on the driving axle an accuracy of 1 : 6350 can be obtained, which is sufficient for ordinary purposes. In any case it is much to be regretted that such a useless encumbrance of our daily life, and such an obstacle to foreign trade, as the English system of weights and measures has not yet been abolished.

Among other external factors which influence the technical side of industries are the patent laws of the various countries—a subject on which the most divergent opinions have been pronounced. It would lead me too far if I attempted to discuss all the features connected with the patenting of inventions, but I should like to draw your attention to the fallacy of considering a preliminary examination, as practised in the United States, for instance, to be of any advantage to an inventor. That system of examination involves as much trouble and expense as a lawsuit, but it is no bar to a lawsuit being commenced later on, and then the same case has to be argued over again. A favourable result of such an examination is, therefore, in no way a guarantee of the validity of the patent—on the other hand, I willingly admit that anticipations may be detected by this search. It is, however, the business of an inventor to find out for himself what has been done before, and to make himself thoroughly acquainted with his subject before he begins to suggest improvements. In this work he should be assisted by the staff of the Patent Office, where a reference library for technical subjects should be at his disposal, containing not only patents, industrial designs, or models and trade marks, as prescribed by Article XII. of the International Convention for the Protection of Industrial Property, but also files of the principal technical and scientific periodicals and transactions. Searching such records will prove to be a liberal education, and will in the end be of greater advantage to the inventor than having this work done for him by the members of the staff, who cannot be as

Digitized by Google

well qualified to make the search as the inventor himself, as their acquaintance with the essential features of a new device is necessarily inferior to his.

Other branches of legislation besides the patent laws affect industries directly or indirectly, either by prescribing measures for safeguarding health and life, or by laying down rules for the building of factories, or by dealing with the liability of employers in case of accidents. With all these I do not propose to deal in further detail, as I hope that by merely outlining the influences under which industrial work is carried on, I have made it clear that they are very numerous and of the most varied character. It is, therefore, extremely difficult to foresee what consequences a serious alteration of some of the existing conditions will entail, while it would be quite wrong to draw conclusions about them from a comparison of the industrial state of a country at the present time with its position before railways, telegraphs, and other modern contrivances revolutionised the intercourse between nations. By their aid manufacturers in any country are now in a position to make themselves quickly acquainted with the latest improvements affecting their business that may have been discovered anywhere, and they can also ascertain without much delay and with very little trouble what the requirements are of the remotest communities. In this respect manufacturers of all countries are now competing on an equal footing, where formerly those of one country may have had great advantages over the others.

Another cause of change has been the desire of many countries to create their own industries instead of depending on foreign supplies, and it is not very wonderful that the British industries have new rivals where 60 years ago they had absolute command of the markets. If complaints are now raised that this foreign competition is ever increasing, and proposals are made to protect British industries against it, two points require particular attention. One is that it is hopeless to endeavour to re-establish the former monopoly, and the second that it might be useful to investigate whether the former industrial supremacy has not led to neglect in many respects, for which we now have to suffer. Whatever remedies may be proposed to enable British industries to hold their own in the general competition, there is in my opinion only one safe test for selecting the right ones, and that is that their adoption should lower the cost of production for the benefit of the whole community.

A SCIENTIFIC INVESTIGATION INTO THE POSSIBILITIES OF GAS-TURBINES.*

BY R. M. NEILSON, ASSOCIATE MEMBER

(*Concluded from page 674.*)

It will be seen that it has been assumed that the gas and steam expand adiabatically separate from each other. The adiabatic curve of the one is different from that of the other, as the specific heats are different; and while the gas falls to a temperature of 140deg. C. (413deg. absolute C.), the steam falls only to 184deg. C. (457deg. absolute C.). This will be correct if the steam and gas are not mixed. It is much simpler to consider this case than to consider the case where the gases are intimately mixed. In this latter case the diagram Fig. 16 would be altered, and it could not so easily be seen where the loss of efficiency came in. In practice, however, it will probably be found convenient to mix the gases. This will alter the diagrams and the efficiency somewhat; but what has been considered gives a good idea of the general effect of the employment of steam in conjunction with gas. If the steam and gas are not mixed, a condenser could be employed for the former. The steam could then be expanded to a much lower temperature and pressure, and the efficiency would be considerably raised.

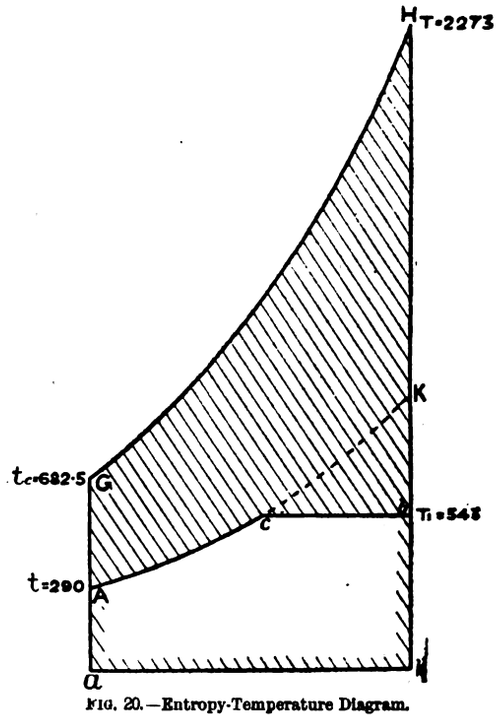


FIG. 20.—Entropy-Temperature Diagram.

Cycle II. could be modified in the same way as Cycle I. was modified by combining steam with the gas. A case of this nature has not been worked out, but Case 1 of Cycle II. could probably be modified in this way. Case 2 of Cycle II. could not be so treated on account of the high ratio of negative work to gross work that would occur.

One might try to improve on all these cycles by extending the adiabatic expansion line of the gas below atmosphere, instead of stopping it at atmospheric pressure. It would, of course, be necessary to compress the fluid back again to atmospheric pressure; but if this compression is isothermal, or between the isothermal and adiabatic, there will be an increase in efficiency. Carnot's cycle is, in fact, being approached in the lower part of the diagram.

Figs. 19 and 20 are respectively pressure-volume and entropy-temperature diagrams of Cycle I., Case 3, modified

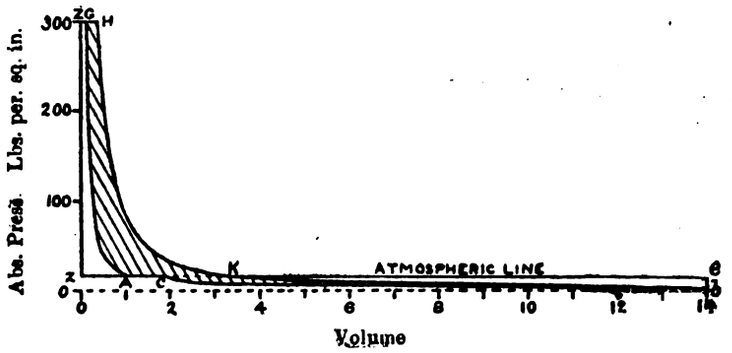

FIG. 19.—Pressure-Volume Diagram.

by continuing the adiabatic expansion to a pressure of 2lb. per square inch absolute. The scale for volumes in Fig. 19 has for convenience been made half of that of the other diagrams. K *b* represents the addition to the adiabatic line of expansion, and *b c* represents isothermal compression of the gas from 2lb. absolute at *b* to 15lb. absolute at *c*. There should be no difficulty in a turbine in extending the expansion from K to *b*. There may be difficulty, however,

* Paper read before the Institution of Mechanical Engineers.

Digitized by Google

in getting isothermal compression from b to atmospheric pressure at c. As the volume at b is 14 times the initial volume, it will be desirable to get the fluid discharged as quickly as possible. A rotary compressor will probably be best for this purpose. A compression sufficiently near to the isothermal and sufficiently remote from the adiabatic to appreciably raise the efficiency should be obtainable. The temperature at b is 270deg. C. (543deg. absolute C), and if the compression is isothermal, this will, of course, be the temperature all along the line $b\,c$. The gases could be passed through or around water-cooled tubes to keep down the temperature during compression. With the gas at a temperature of 543deg. absolute C. it would not do to spray water into it, unless sufficient water were sprayed to cool the gas below the boiling point of the water, which is 326deg. absolute C. at this pressure. If compression takes place along the isothermal line $b\,c$, a net amount of work will be gained, represented by the area K $b\,c$. The gas will be discharged into the atmosphere at c, the volume at discharge being 1·874 of the original volume (at A) Even if the compression is not isothermal, an amount of work may be gained which will wipe out the extra losses in the machine, provide for pumping out the cooling water, and may leave a margin of net gain.

In Fig. 20 the heat absorbed by the fluid is represented by the area a G H k, the heat rejected by the area a A c b k, and the heat converted into work by the area A G H $b\,c$. As the heat absorbed remains unchanged, while the heat converted into work is increased by the area K $b\,c$, E, is, of course, increased.

$$E = \frac{\text{area A G H } b\,c}{\text{area A G H } k}.$$

This enlarging of the diagram, of course, affects the ratio of negative work to gross work. Referring to Fig. 19,

$$\text{gross work} = \text{area } z\,\text{Z H K } e\,b\,c$$
$$\text{negative work} = \text{area } z\,\text{Z G A} + \text{area K } e\,b$$
$$\text{net work} = \text{area A G H } b\,c$$
$$\frac{\text{neg. work}}{\text{gross work}} = \frac{\text{area Z G A} + \text{area K } e\,b}{\text{area } z\,\text{Z H K } e\,b\,c}.$$

In the free-piston explosion engines, at one time in fairly common use, of which the best known is the Otto and Langen, the expansion was carried to a pressure considerably below the atmosphere. The compression to atmospheric pressure which followed this must have been between the isothermal and the adiabatic.

If this continuation of the adiabatic expansion below atmospheric pressure is not found to be advisable to the extent that has just been described, it may be found advisable to a less extent. If it is found advisable in any case, it is more likely to be so in a case in which the high pressure of the gases after combustion is reduced to a low pressure in divergent nozzles before the gas is allowed into the turbine casing, than in a case in which the whole fall of pressure takes place in the turbine casing. In the former case very high vane speeds are necessary, and the friction between the rotating parts and the fluid in the casing is an extremely important matter. The reduction of the pressure within the turbine casing from atmospheric pressure (or above that) to one-quarter or one-eighth of that amount may, therefore, very much reduce the frictional losses. It is true that the rotary pump, if such is employed for completing the cycle, has to deliver at atmospheric pressure, but the rotating parts of the pump can revolve at a much lower speed, and the friction therefore be of much less consequence.

With such high-speed turbines there is another question to be considered. It has been stated in discussing Cases 3A and 4A of Cycle I. and 1A and 2A of Cycle II. that the velocity of the gases escaping from the divergent nozzles would be over 4,000ft. per second if the heat energy converted into kinetic energy was as mentioned. The author is not, however, aware of any results of experiments having been published in which velocities of these amounts were obtained when the pressure of the medium into which the divergent nozzle discharged was atmospheric. It is supposed by some that there is a maximum limit to the velocity of a gas leaving a divergent nozzle and escaping into a given medium which is at a given pressure, etc., and that this limiting velocity is dependent on the pressure in the medium into which the nozzle discharges, and is less when the pressure in this medium is greater, and *vice versâ*—that is to say, it is supposed by some that, after a certain velocity of discharge has been attained, no increase in the initial temperature or pressure will increase this velocity; but a reduction of the pressure in the medium may increase this velocity. The author does not express any opinion himself on this point, but if it should be found that the reduction of the pressure inside a turbine casing below atmospheric pressure enables us to convert the heat energy of our gas into kinetic energy more effectively, this will be a further argument in favour of so reducing the pressure. Whether or not there is an advantage to be gained remains to be proved, but there is at any rate a possibility of gain by thus extending the expansion, and a possibility which, in the author's opinion, should not be ignored. In dealing with large volumes and small pressures there is, as already mentioned, an immense difference between turbines and reciprocating engines.

Cycle IV.

The fourth cycle which will be considered in this paper is one in which a high ideal efficiency can be obtained with a low compression, and without having an abnormally high ratio of negative work to gross work. Figs. 21 and 22 are respectively pressure-volume and entropy-temperature diagrams for an engine working on this cycle. In explaining the cycle it is best to start at E^1. At this point the temperature of the fluid is 1,592deg. C. (1,865deg. absolute C.), and the pressure is 30lb. absolute.

Let the fluid be heated by combustion at constant pressure along the line $E^1\,C^1$ till the temperature reaches 2,000deg. C. (2,273deg. absolute C.). Now let the gas expand adiabatically from C^1 to D^1 till the pressure is atmospheric. The temperature will then be 1,592deg. C. (1,865deg. absolute C.). Now let the gas pass through a regenerating chamber and be cooled at a constant pressure from D^1 to F^1 till the temperature is 80deg. C. (353deg. absolute C.). The gas escapes at F. into atmosphere, and thereafter cools at constant pressure to 17deg. C. (290deg. absolute C.) at A. A new charge is taken at A and compressed adiabatically to B^1, where the pressure is 30lb. absolute and the temperature 80deg. C. (353deg. absolute C.). The fluid is now passed through the regenerating chamber, and is heated at constant pressure along the line $B^1\,E^1$, taking back the heat given up by the last charge. This will raise its temperature to 1,592deg. C. (1,865deg. absolute C.) and place the fluid in the condition it was at the start.

Referring to Fig. 21, the gross work is represented by the area g^1 G^1 C^1 D^1, the negative work by the area g^1 G^1 B^1 A, and the net work by the area A B^1 C^1 D^1.

$$\therefore \frac{\text{negative work}}{\text{gross work}} = \frac{\text{area } g^1\,\text{G}^1\,\text{B}^1\,\text{A}}{\text{area } g^1\,\text{G}^1\,\text{C}^1\,\text{D}^1} = 0{\cdot}16\ (0{\cdot}1553).$$

The heat absorbed by the fluid (other than that obtained in the regenerator which was given up by a previous charge) is represented in Fig. 22 by the area e E^1 C^1 d. The heat rejected (other than that given to the regenerator) is represented by the area a A F^1 f. The heat converted into work is represented by the difference of these two areas.

Now, area A B^1 C^1 D^1

$$= \text{area } a\,\text{B}^1\,\text{C}^1\,d - \text{area } f\,\text{F}^1\,\text{D}^1\,d - \text{area } a\,\text{A F}^1\,f$$
$$= \text{area } a\,\text{B}^1\,\text{C}^1\,d - \text{area } a\,\text{B}^1\,\text{E}^1\,e - \text{area } a\,\text{A F}^1\,f$$
$$= \text{area } e\,\text{E}^1\,\text{C}^1\,d - \text{area } a\,\text{A F}^1\,f.$$

$\therefore$ area A B^1 C^1 D^1 represents the heat converted into work.

$$\therefore E = \frac{\text{area A B}^1\,\text{C}^1\,\text{D}^1}{\text{area } e\,\text{E}^1\,\text{C}^1\,d} = 0{\cdot}84.$$

The ideal efficiency is high; but the highest actual efficiency which could practically be obtained would be very much below this. Besides the losses in the motor proper and in the pump, there would be a very great loss in the regenerator. It would not be practicable to reduce

Digitized by Google

the temperature of the exhausting gases in the regenerator to 80deg. C., or to raise the temperature of the fresh gases in the regenerator to 1,592deg. C.

If the losses in the regenerator and in the passages leading to it and from it amounted to 50 per cent. of the heat which is ideally given to or taken from the regenerator, these losses would have to be made up by extra heat given to the fluid by combustion, and the efficiency would fall to 0·3. This does not take into account the losses in the motor proper and in the pump. The heat losses in the motor would probably be very great. This cycle may, however, when used with turbines give results sufficiently good to justify its use. It certainly seems to promise better results with turbines than with reciprocating engines on account of the lower frictional losses than might be expected with turbines. With reciprocating engines the large volumes and the low pressure of the fluid would cause extremely high percentage losses in friction.

The cycle has the disadvantage that gas at a very high temperature has to be conveyed from the regenerator to the turbine. This practically forces us to have the turbine quite close to the regenerator. It would seem to be necessary to build the regenerator of brickwork, and to build the turbine into this brickwork. This will very much limit the usefulness of the cycle, as it will be quite unfeasible in many cases either to have a regenerator of the nature required at the place where power is wanted, or to transmit the power from a place suitable for holding the regenerator. Nevertheless, there will be cases in which it will be quite practicable to build a regenerator beside the turbine, and this cycle would therefore seem to be worthy of consideration. A rotary pump driven from the turbine spindle could easily be used for compressing the gases, thus simplifying the mechanical moving parts.

The several cases can be compared in the table. It will be seen that high ideal efficiency is, as a rule, accompanied by a high ratio of negative work to gross work. Cycle IV. is, however, an exception to the rule. The cycle has the highest ideal efficiency and the lowest ratio of negative work to gross work. As has been already pointed out, however, the efficiency which we could actually hope to obtain with this cycle would be very much below the ideal, and the cycle has other objections, as already stated. Cycle I., Case 1, has a high ratio of negative work to gross work, although the efficiency is the lowest. This is because all the heat is supplied to the gas at a comparatively low temperature.

Engineers interested in any particular cycle can work out other cases for themselves if they consider it necessary, but it is suggested that, after a careful perusal of this paper, the effect of any change can be guessed at with fair accuracy. It might be possible to use the exhaust gases from a turbine working according to Cycle I., Cases 1 and 3, or Cycle II., Case 1, to heat the fluid after compression, and so to save fuel. Consider Fig. 4. The heat supplied to the fluid is represented by the area *a* B C *d*. Part of this heat might be obtained from the hot exhaust gases and the efficiency of the cycle thus raised, as will be clear from the description just given of Cycle IV. With Cycle I., Cases 1 and 3, and Cycle II., Case 1, there should be no necessity to use a regenerator of brick or such like refractory material. The exhaust gases could be passed through tubes, and the fresh air passed over the outside surfaces of the tubes, or some equivalent construction employed. Many other cycles or modifications of cycles might have been investigated, but the author has considered it inadvisable to burden the paper with them. As regards the Carnot cycle, an engine working on this cycle would have the same value for E as one working on Cycle I. for the same values of t and t_c, and if the isothermal expansion were carried far enough, it would, under ideal conditions, do the same work per cycle for the same amount of fluid, and have the same ratio of negative work to gross work. The maximum volume of the fluid would, however, be very much greater, and although this is not such a serious matter with a turbine as with a reciprocating engine, it is, nevertheless, not a condition to be accepted without due recompense.

FIG. 21.—Cycle IV. Pressure-Volume Diagram.

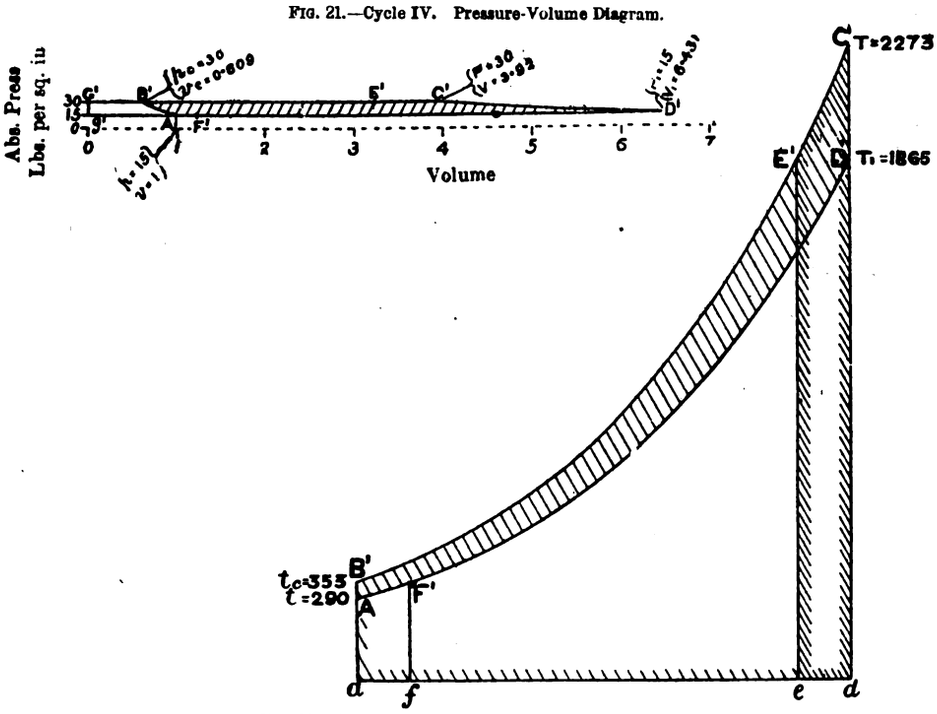

FIG. 22.—Cycle IV. Entropy-Temperature Diagram.

TABLE COMPARING THE SEVERAL CYCLES AND CASES.

Cycle.	Case.	Compression. Temp. abs. C.	Compression. Press. lb. per sq. in. abs.	Max. temp. abs. C.	Max. press. lb. per sq. in. abs.	Ideal efficiency (E).	Ratio of neg. work to gross work.
I.	1	389	42	973	42	0·25	0·40

III.	2	682·5	300	2,273	300	0·33	0·41
IV.	—	353	30	2,273	30	0·84	0·16

If an engine working on Cycle I. has $T_1 = t_c$, then an engine working on the Carnot cycle with the same values of t and t_c would require, in order to do the same work, to commence its adiabatic expansion at the point where the engine working on Cycle I. leaves off. If p and P_1 on the Cycle I. engine are atmospheric pressure, then on

Digitized by Google

the Carnot cycle engine the whole of the adiabatic expansion would take place below atmospheric pressure. It is interesting to compare the Carnot cycle with other cycles, but it hardly seems useful in the present investigation to devote any more space to this

Although the practical efficiency of an engine is usually of great importance, there are many occasions on which a very poor efficiency will be tolerated if other conditions are satisfactory. Small gas-engines using lighting gas, costing 2s. to 3s. per 1,000 cubic feet, are employed in great numbers although the fuel cost per brake horse-power hour is very high. Small electromotors are extensively used consuming current which costs over 2d. per Board of Trade unit. The fuel cost and the energy cost respectively in the two cases are high, but the user prefers to put up with this rather than employ a power plant which has a higher initial cost or which requires more attention or is generally more inconvenient.

If, therefore, small gas-turbines could be sold at a low price, and if they required little attention and did not readily get out of order, they might be in great demand, even although the gas consumption per brake horse-power hour was high. With the average user of a small engine, producing, say, 100 brake horse-power hours per week, a reduction of £10 in the initial cost is of more consequence than a reduction of two cubic feet per brake horse-power hour in gas consumption. The same user would no doubt be quite willing to allow an additional five cubic feet of gas per brake horse-power hour if he was saved trouble and anxiety and small expenses in the working of the engine.

To produce a gas-turbine cheaply, it would seem necessary to entirely avoid reciprocating parts, and to be content with a low compression. Cycle I., Case 1, would seem to lend itself to cheapness of construction and simplicity, but it might be advisable to reduce the compression at the expense of efficiency. A rotary pump could undertake the compression.

In many cases the vibration of a reciprocating engine is extremely objectionable; and a motor that ran with practically no vibration would be popular even if its initial cost was greater and it was more extravagant of fuel. In motorcars, for example, oil or spirit explosion engines are used for their lightness and compactness; but the vibration they cause is objectionable. If a satisfactory turbine were obtainable, there is no doubt that motorcar builders would eagerly buy it and instal it on their motorcars, even if the cost was greater and the efficiency less than many arrangements of explosion reciprocating engines now in use.

One might mention many other uses to which gas-turbines could advantageously be put if they were obtainable as fairly efficient and reliable machines. In many factories and engineering works electric motors fed by current from a central station are used to drive individual machines or groups of machines in order to save the losses and inconveniences produced by driving by belts or ropes. Gas-engines (reciprocating) have been used to a limited extent for the same purpose, but the foundations required by these and the vibration caused by them have prevented their extensive use. If a gas-turbine were obtainable which could be set down anywhere like an electric motor it would serve splendidly for this purpose, and in order to displace electric driving it would only require to possess an efficiency greater than the efficiency of the central-station engine multiplied by the efficiencies of dynamo, mains, and motor.

Suction gas producers are coming into extensive use, and by their means gas-engines can take the place of steam-engines in places where they otherwise could not. Whatever objections there may be to the supply of gas to gas-engines from these suction producers, these objections should be less rather than greater with turbines than with reciprocating engines.

The power of a gas-turbine could be effectively varied with an insignificant variation of speed by cutting out one or more of the nozzles or admission ports which admit the fluid to the turbine buckets or first set of buckets when several are employed in series, the fluid being passed through the acting ports or nozzles at a uniform pressure and with a uniform velocity. To enable the acting nozzles or admission ports, no matter how many may be in use, to deliver the fluid always in the same uniform manner, it will be necessary, if one flame supplies all the nozzles or admission ports, to control the fuel and air supplies to the flame in conjunction with the mechanism which cuts off the nozzles or admission ports. It will, however, be usually advisable to supply the air and fuel to the flame at a constant velocity, and, although this could be done when one flame supplied a varying number of nozzles, this would involve complications; and it may, therefore, be found expedient to have a separate flame and a separate combustion chamber for each nozzle. This will, however, involve the necessity of igniting or extinguishing a flame for each change of power, and although this could be done automatically, it is objectionable. Much careful consideration will be required to determine which is the least evil to put up with and which course had better be taken.

It is hoped by the author that this comparison of the several cycles treated on will be of some use in showing what may be expected from any of these, and which will be best suited for a motor which is required to work under given conditions, and which it is important should have given characteristics. One cannot, however, compare the several cycles and estimate the actual efficiencies, etc., which one could expect to obtain in practice in anything like so satisfactory a manner as could be desired, without having more information obtained by experiment on the following three points: (1) Losses in pneumatic compression to high pressures—(*a*) with reciprocating compressors; (*b*) with rotary compressors; (*c*) with a combination of reciprocating and rotary compressors. (2) Expansion of hot gases in divergent nozzles. (3) Radiation losses and transference of heat from gases to metals at high temperatures.

It would immensely aid the solving of the gas-turbine problem if a thorough set of experiments on these three points were made and the results published. This would, of course, cost a considerable amount of money, but the information obtained by the engineering world would be very good value at the price. Money has been spent and is being spent by engineering and scientific societies on investigations which, while no doubt interesting and instructive, are not of so far-reaching importance as experiments which would materially aid in the production of a successful gas-turbine.

SMALL TALK BY THE LOW-CASTE WIREMAN.

BY "JACK BLOGSON."

The following effusion makes no pretence at taking a logical line of thought. It is, in fact, simply a big grumble at the present state of electrical work and systems. However, it is to be hoped it will strike a goodly number of readers as possessing some horse sense, particularly regarding the position an apprentice finds himself in at the end of his term. Evidently it all reduces down to a conflict between influence and training, and who can say but the former gains the day in nine cases out of ten. Whilst reading the "Old 'Un's" letters, which lately appeared in this journal, one would fancy most aspiring (perhaps impecunious) young engineers would feel a trifle envious of the imaginary "Young 'Un," with his free choice of shop and college. Some of the latter letters indulged in a pretty hard shot at the unspeakable, beer-guzzling, horse-backing, working-man, who is so infinitely below the "Young 'Un's" standing. Now, how many shop foremen will dispute the fact that the state of things represented is completely reversed, as this dazzling high flown pupil usually manages to borrow some cash from the foreman (especially on a country job), which is usually paid back on what is known as the "Kathleen Mavourneen" system—"It may be for years, and it may be for ever."

But to resume the grumbling. The following will no doubt be of interest to some readers: Eight pupils, apprentices, or whatever name you please to apply to them, paid fees averaging each £100 to a certain firm of electrical contractors. In return they were supposed to acquire "the art, trade, and profession of electrical engineers."

Digitized by Google

Some, when they had their term completed, were generously proffered a situation by the manager at sums varying from 20s. to 25s. per week, they at this time being well qualified to execute wiring work, the rate for which is 8d. per hour. Others, owing to the lack of capacity, and perhaps thirst, were ignominiously fired out with an excellent reference personally written by the governor.

Now, a brief account of how these individuals fared up to the present may interest readers. Taking them in numerical order: No. 1 turned out a fairly good plant and wire man; not being afforded an opportunity of acquiring a knowledge of estimating and draughtsman work, and having no influence to pitchfork him into a good berth, he developed into a journeyman wireman. No. 2, good post in power station (desperate pitchforking). No. 3, very indifferent man; travelling round like a wandering Jew victimising contractors. No. 4 has abandoned the electrical business, and has settled down to farming at home. No. 5 has an income at his back, and has consequently been on the lookout for a nice congenial job at, say, £800 per annum. Vain hopes! No. 6 opened a high-class bar and billiard-rooms; getting rich rapidly. No. 7 secured a good station job (foreign) on his own merits. No. 8, in America; no tidings.

Now, any young fellow can, with a little trouble, get into a shop providing he does not want a salary to commence with, and if he has that invaluable gift—observation—and applies himself to study, there is no earthly reason why he should not develop into a good workman in time. What, then, is the mental calibre of a person who demands and accepts large sums, as in the foregoing cases, without giving his pupils any more facilities of becoming a thoroughly experienced engineer than the youth whose aim is simply to become a wireman? Now, again, referring to our eight examples. Nos. 7 and 2 are practically the only cases who have secured decent posts. The latter may certainly burst up the station, but as the old proverb has it, "The devil takes care of his own." Nos. 1, 3, and 8 have descended to the level of the "Old Un's" fourth caste—wireman or workman. No. 5 is the personification of what the "Young One" should develop into. No. 6 deeply regrets the time he spent at the business, but can argue the point about the correctness of his meter readings with the power-house officials until they become black in the face. He regards it now as very surprising that apprentices will work hard for the employers or masters and pay them to let them (the apprentices) do so. Now, several of the above youths were well posted both practically and theoretically on finishing up, and if they could possibly step into even a ticklish job would certainly manage to hold it, they, of course, then being fresh from practice, science classes, etc. But folks cannot possibly wait for 18-carat chances to arrive, or subsist on their unfortunate relatives for a lifetime. The immediate result of this is: our smart apprentice, instead of becoming a future shining light in the electrical firmament, tackles a conduit job instead and gets his fingers pulled in with the wires by the new nipper, who has come to the line with the very sensible intention of being a workman or wireman, no more or less. Why even a wireman's job is scarcely worth all the trouble, training, and experience required to fill it properly.

Let us consider the various classes of work he is called on to execute, and which every qualified man can do: wiring in several systems, casing, both socket and screwed conduit, lead-covered and concentric, telephone and bell work, motors, arc lamps, ability to work from plans and blue prints, perhaps some gas and oil engine work thrown in, etc. Though the list looks a bit formidable, a good man has had experience at everything above specified, and that without, perhaps, ever troubling his brains as to the meaning of $4\pi nc$L. Another very noticeable thing is the way the various sub-divisions of the electrical business blend together in this country. It is nothing unusual to find a workman who was, we will say, on house-wiring a while since, running a plant to-day, to leave, perhaps, in a month and tackle telephone work. Of course, the individual may acquire a better training, but would it not be better to specialise things a little?

I have before me now a copy of the rules of the International Brotherhood of Electrical Workers. Some of those could certainly be used universally with the greatest advantage. Space will allow only a few to be quoted. Section 48 is of interest. It provides for the salaried business agent to visit as many jobs as possible in his district weekly, asking each workman for his card, and punching same. This speedily stops non-union and union men working on same job. The I. B. E. W. class electrical workers under the following headings: (1) armature winders; (2) journeymen wiremen; (3) shopmen; (4) maintenance men; (5) switchboard and dynamo attendants. The wireman's work comprises "the installation and repair (unless done in shop) of all devices by which the energy or force known as electricity is utilised." A shopman's work is done in shop only. A "maintenance man" is defined as a man in charge of an isolated plant; his work includes keeping arc lamps and motors in order, "but shall not include running new circuits for light or power, or the construction or installation of signs or display lights." Switchboard and dynamo attendants, Class 5, refers to station work. Section 61, Rule 10, is extra good: "Not more than one man connected with a firm, whether a partner or stock holder, shall do journeyman's work, and he must have a working card . . . Taking in a partner or working member simply to have a *cheap man around* (the italics are mine) will not be recognised." Section 61, Rule 13, forbids all apprentices or helpers working on a job unless a journeyman is also on the same job. Section 73 says: "Any member who refuses to show his wages when requested by another shall be fined 5dol." Section 73 may possibly lead to some trouble on this side of the water, but, certainly, if some of the I.B.E.W. rules were adhered to by men and masters, and a system of examination organised and adopted, it would certainly give a *bonâ fide* man a chance, and also stop the influx of cycle mechanics, scene shifters, labourers, etc., whose presence is so detrimental to the industry both in the eyes of trained workmen and the public.

MANCHESTER STREET-LIGHTING.

The following is the full text of an interesting report presented by Mr. S. L. Pearce, the chief electrical engineer to the Manchester Corporation, to the special Street Mains Sub-Committee. We have, however, cut out the list of streets as not being of general interest. The report is dated Oct. 11, 1904, and reads as follows:

Report on Street-Lighting with New Arc Lamps.

Gentlemen,—I now have the pleasure to report that the whole of the alterations to the existing system of street-lighting, together with certain extensions thereto as sanctioned by you in March last, have been carried out, and that important data and figures have been obtained therefrom as to costs and illuminating effect, these results being embodied in the present report. It may be of interest to state briefly what has been done during the past few months. The six old open-type 10-ampere Crompton lamps in front of the infirmary on Piccadilly have been replaced by nine nine-ampere enclosed Gilbert lamps. In addition, 12 six-ampere lamps of the same make have been placed on the centre poles of the tramways running from Portland-street to Mosley-street. The old 16 Brockie-Pell 10-ampere open-type lamps in Albert-square have been replaced by six ampere Gilbert lamps to the same number. In St. Ann's-square the old six Brockie-Pell lamps have been replaced by new Gilbert lamps, and two more have been added, one on either side of the centre of the square. These latter took the place of the gas lamps that were taken down. We have, therefore, in all, now 45 lamps, and so far the new Gilbert type of lamp has given great satisfaction, burning with a clear and very steady light for at least 120 hours without recarboning, trimming, or any attention. The current consumption is, as stated by the makers, 600 watts, or six amperes at 100 volts, equivalent to seven-tenths of a unit per 1,000 candle-power hours.

Under the superintendence of Mr. Ratcliff, the head of the testing department at the Polygon, an extensive system of comparative tests have been made between (1) the new arc lighting, (2) the intensified gas system, and (3) the ordinary incandescent gas lamps on a portable street photometer, kindly lent me for the purpose by the technical school authorities. The results of these tests are shown in the form of curves appended to this report. The readings were all taken at a height of about 4ft. 6in. from the ground, this being the most regular height for measurements of this class. The results are expressed in

Digitized by Google

the usual illumination units—viz., "candle-feet"—or, in other words, the particular illuminating effect at any point is expressed in terms of the equivalent number of candles at a distance of 1ft. away from that point. Ordinary street-lighting illumination varies from ·03 to 1·5 candle-feet. Anything over one candle-foot is very good, and over 1·5 candle-feet exceptionally good. Lines are shown giving the mean illuminating effect, and also approximate curves for the candle-power given from the different lights. The curves show clearly the effect from lamp-pole to lamp-pole. The maximum candle-powers observed were as follows: Piccadilly, nine-ampere arcs, 1,152 c.p.; Albert-square, six-ampere arcs, 850 c.p.; Piccadilly, six-ampere arcs, 753 c.p.; Sackville-street, intensified gas (three burners), 525 c.p.; All Saints', incandescent gas, 312 c.p.; Parker-street, "Scott-Snell" gas (one burner), 291 c.p.; Cheetham Hill-road, incandescent gas, 147 c.p.

difference in the candle-powers of the respective lamps, this is an interesting result, as it disposes of the statement that the electric arcs in Manchester do not diffuse their light so well as the gas.

Diagram 3 shows the curves for the centre-pole arcs in Piccadilly and incandescent gas in Cheetham Hill-road. The lamp-poles in the latter locality are 200ft. apart, and the curves show that at a greater distance than about 50ft. from the posts there is no illumination at all. This would be a good route for the adoption of arc lighting.

The question of comparative costs I have already submitted an estimate to you in my report of March 10, and the results obtained have practically borne out those figures, and little modification is necessary. The price hitherto charged for current for street-lighting has been 2d. per unit, but considering that the load factor is a very high one, approximately 40 per cent., the price could be fairly reduced to 1½d. and still

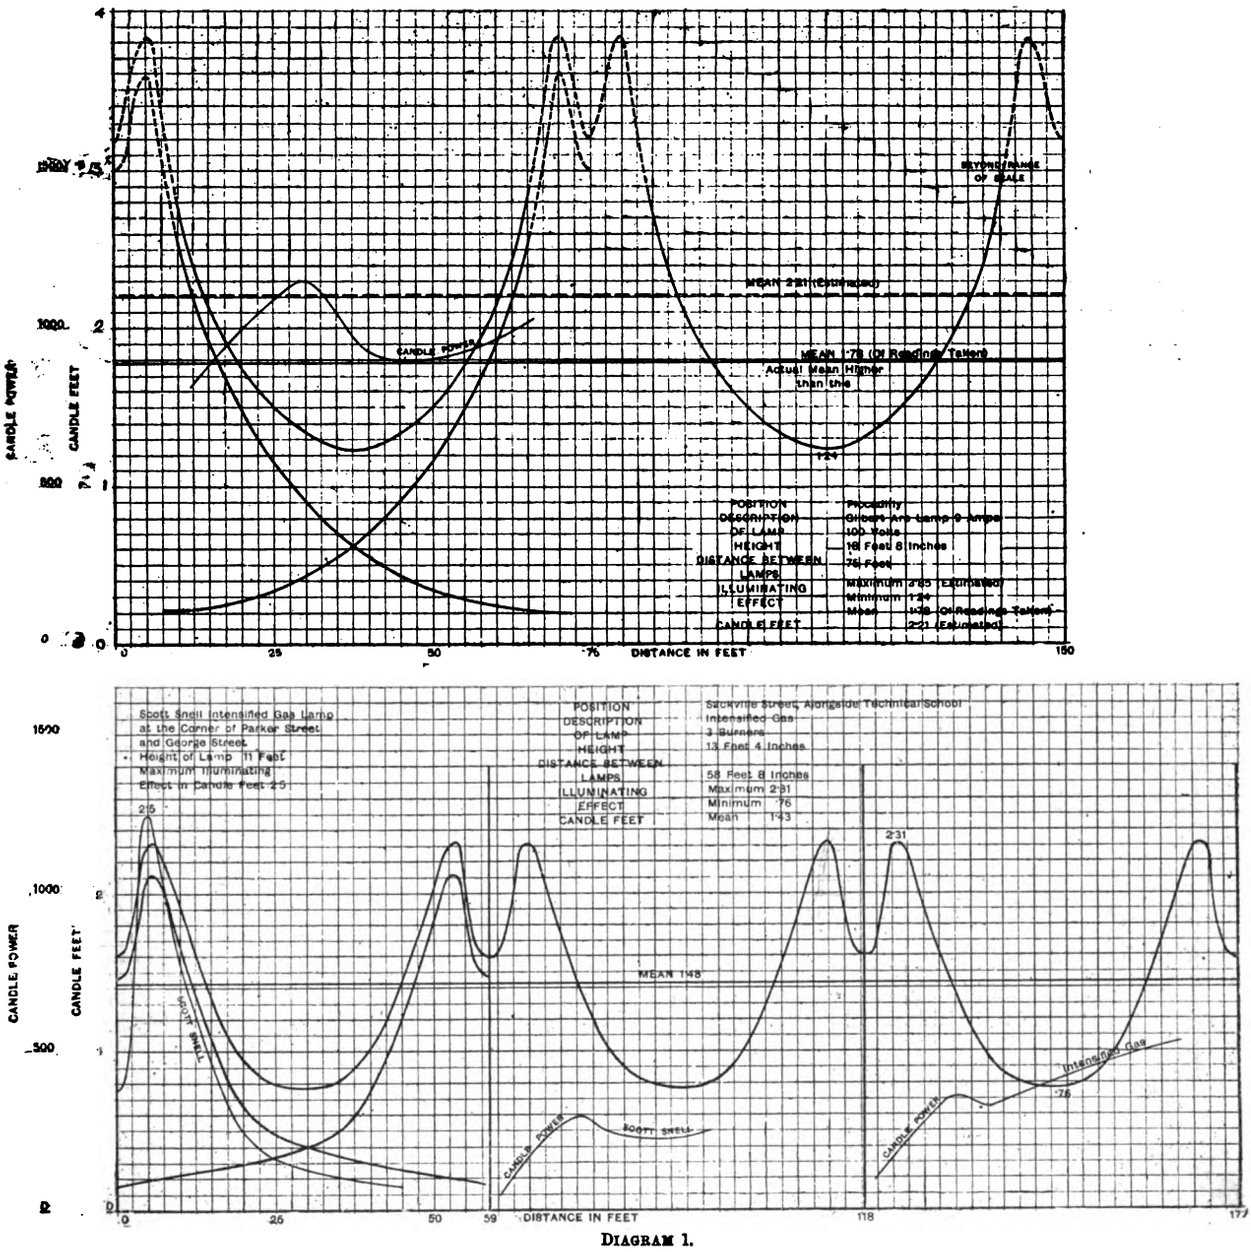

DIAGRAM 1.

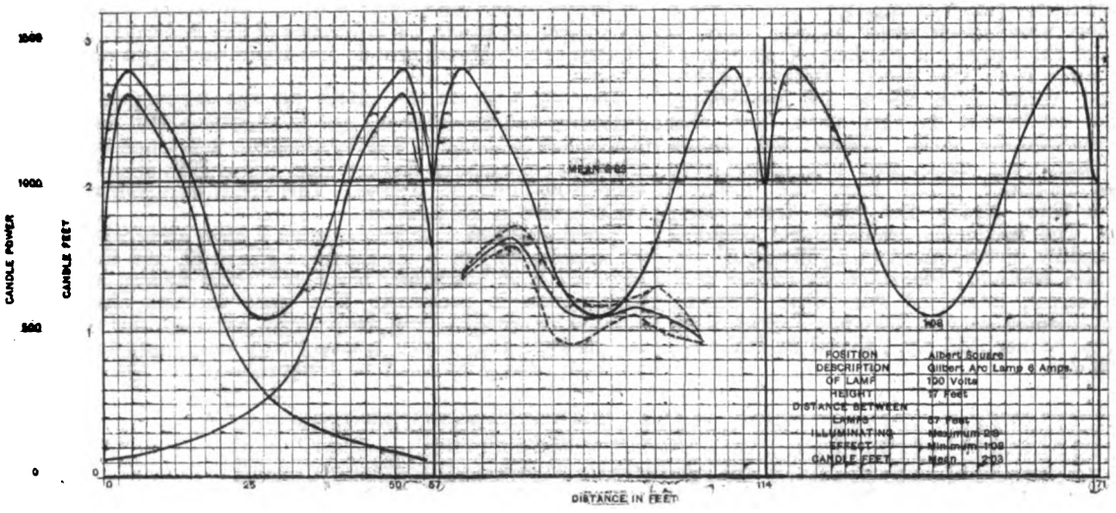
Diagram 1 shows the curves of illumination for the nine-ampere arcs on Piccadilly and the intensified gas lamps round the technical school, which are to a great extent self-explanatory. With the arc lamps the light was so intense within a distance of 10ft. of the poles that the readings were off the scale of the instrument, and the curves had therefore to be calculated beyond a certain point with the help of the results from the six-ampere lamps.

Diagram 2 shows the curves of illumination for the six-ampere arcs in Albert-square and the incandescent gas lamps at All Saints'. It is interesting to compare the former with the "intensified" lighting round the technical school, the lamp-posts being approximately the same distance apart, the mean illuminating effect in the case of the arc lamps being 2·03 candle-feet, as against 1·43 for the intensified gas. It will further be observed that the lowest mean illuminating effect is for the arcs 1·08 candle-feet, and for gas ·76. Allowing even for the allow a margin of profit. The latest available costs show that for a demand of this nature the running and standing charges together only amount to ·95d. per unit, so that there would be a profit of ·3d. per unit, based on the 1½d. rate, irrespective of the fact that the fixed charges are going on now the whole time, whether the demand is made or not. We have at the present time 24 all-night lamps and 21 lamps that are switched out at 11 p.m. Averaging these together, I find that under the new working conditions, and with current at 1½d. per unit, the equivalent price per lamp per annum works out at £11. 17s. 6d. The price charged on the basis of the old working was approximately last year £19 per lamp per annum. It is evident that a substantial reduction could be made in the event of the department obtaining consent to extend the present street-lighting system. Comparing the costs of production for street-lighting as between "arcs" and the "intensified gas," I take the last figure furnished me by the gas department for the latter

Digitized by Google



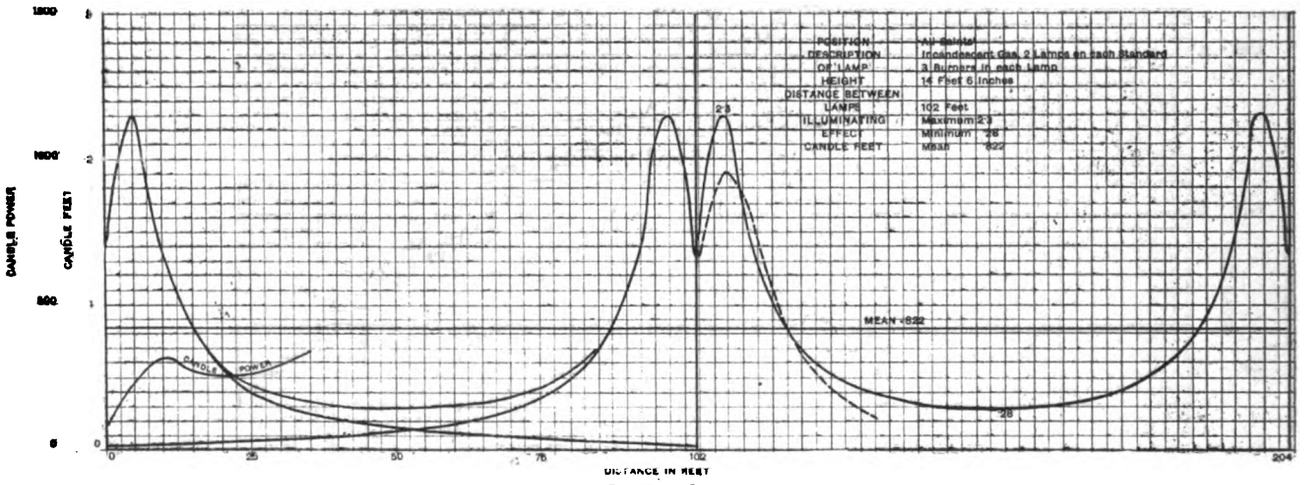


DIAGRAM 2.

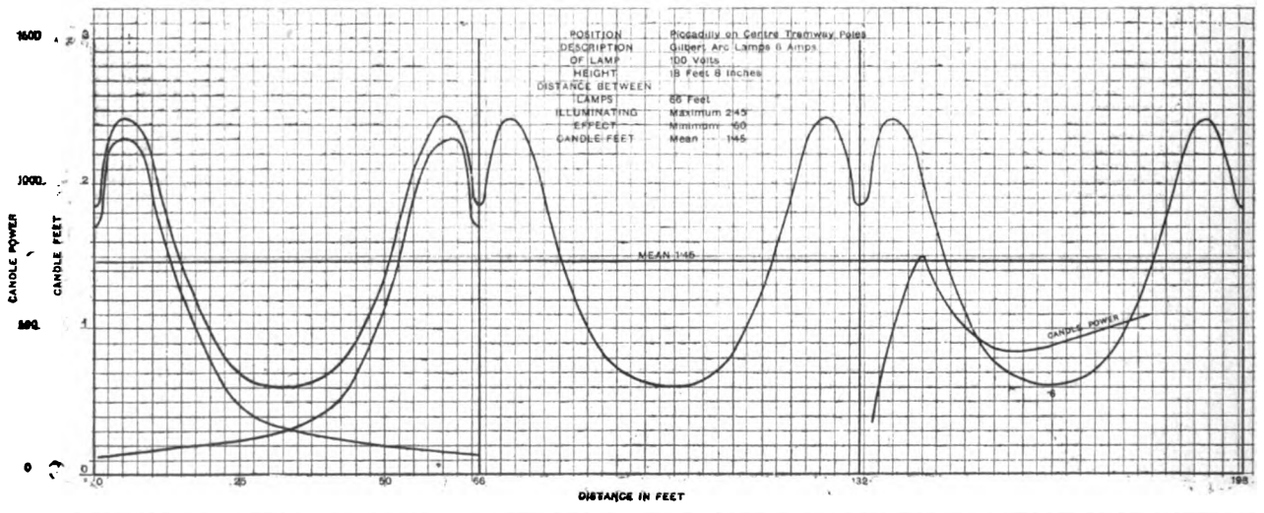

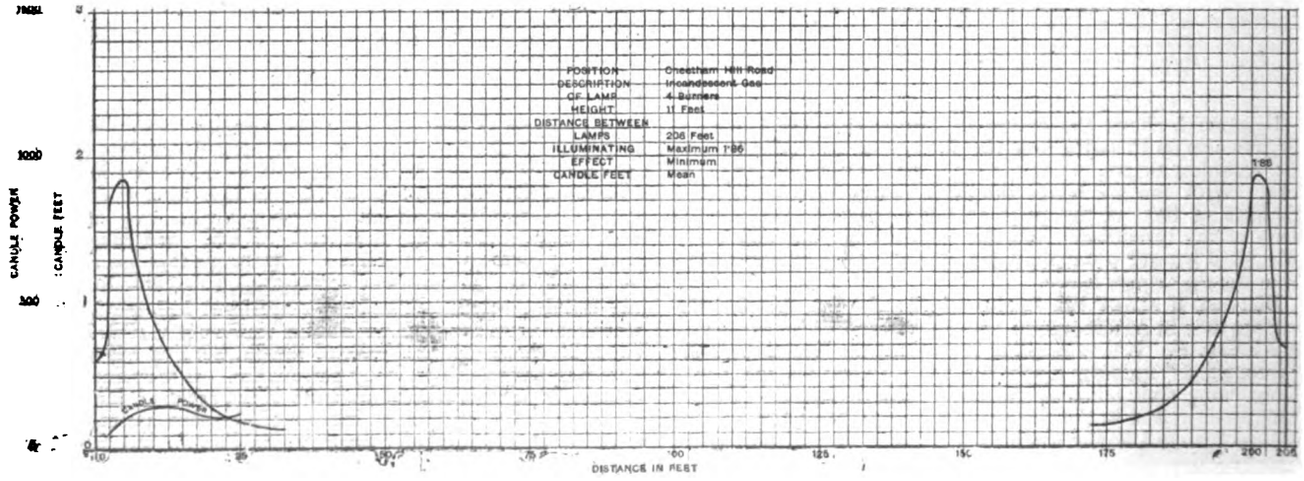

DIAGRAM 3.

Digitized by Google

method, which is at the rate of 1·08d. per 1,000 candle-power hours. I believe this figure also includes for 10 per cent. depreciation.

Gas.—At 4,000 hours of burning, degree of illumination equivalent to 1,000 c.p. : cost = 4,000 × 1·08d. = £18.

Electricity.—Under the same conditions as above : number of units used = $\frac{4,000 \times 7}{10}$ = 2,800 ; 2,800 × ·95d. = £11. 1s. 6d. ; carbon and trimming = 8s. ; depreciation 10 per cent. = £1. 3s. ; total, £12. 12s. 6d. ; equivalent to ·75d. per 1,000 candle-power hours. I have taken the same figure for depreciation for comparison. From calculations made, I find that the costs of illumination in Albert-square and Sackville-street work out as follows :

Albert-square Arcs—Consumption, 600 watts per hour ; mean candle-feet (M.C.F.), taken from curves = 2·03 ; Board of Trade units per M.C.F. per hour = $\frac{600}{2·03 \times 1,000}$ = ·295, which at ·95d. per Board of Trade unit = ·28d. ∴ cost per M.C.F. per hour for arcs = ·28d.

Sackville-street—Intensified Gas—Cost of production, 1·08d. per 1,000 candle-power hours ; equivalent to ·565d. per 525 candle-power hours ; mean candle-feet, taken from curves = 1·43 ∴ cost per M.C.F. per hour for gas = $\frac{·565d.}{1·43}$ = ·395d.

The above calculations, as far as they affect the "arcs," are based on actual measurements taken on the site. These results are based on the results of working of the past few months, and are therefore reliable, and there is only one conclusion to be drawn—viz., that the electricity department can carry out a system of street-lighting that compares more than favourably with the "intensified gas system," both from the point of view of annual cost and illuminating effect.

As the committee are probably aware, we have at the present time a large amount of arc lighting cable laid in various parts of the city. I find this amounts to no less than 22 miles, and the approximate cost of same is £13,000, not one penny of which is bringing in any return ; in fact, the cables never have been put into use yet.

SOCIETY OF ENGINEERS' CONVERSAZIONE.

A most enjoyable time was spent by the members of the Society of Engineers and their guests on Wednesday night last, when a conversazione was held at the Royal United Service Institution, Whitehall, to celebrate the society's jubilee. The president (Mr. D. B. Butler) and Mrs. Butler held a reception from 8.30 p.m. to 9 p.m., the guests, as they arrived, passing thence into the museum, where the band of the 23nd Middlesex Rifles (Volunteers) discoursed sweet music. Variety in the way of entertainment was provided by the Imperial Glee Singers and by Mr. George A. Goodwin, past-president, who delivered an interesting lecture entitled "Japan and the Far East," illustrated by photographic lantern views, before a large audience in the lecture theatre. Mr. Perry F. Nursey, the secretary of the society, must be congratulated on the success which attended the arrangements for the function.

HARROGATE ELECTRICITY ACCOUNTS.

The accounts of the Harrogate Corporation electricity department for the year ended March 31, 1904, show a total expenditure on capital account to that date of £98,751. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are given herewith.

GENERAL BALANCE-SHEET.

Dr. Liabilities.	£	s.	d.
Capital account—amount received	108,190	0	0
Sundry creditors	1,762	15	9
Sinking fund account	3,133	5	4
Reserve fund account	1,100	0	0
Surplus	4,064	2	6
	£118,250	3	7

Cr. Assets.	£	s.	d.
Capital account—amount expended for works	98,751	1	4
Stores on hand	812	6	6
Sundry debtors for current supplied	4,962	17	6
Other debtors	51	14	3
Securities held (cost price)	3,133	5	4
Cash with treasurer	9,438	18	8
Cash in treasurer's hands (reserve fund)	1,100	0	0
	£118,250	3	7

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
To generation of electricity	4,653	1	10
Distribution of electricity	796	6	9
Attending and repairs to public lamps	411	0	6
Rents, rates, and taxes	610	5	8
Management expenses, salaries, etc.	1,180	3	11
Special charges—insurance, etc.	18	17	0
Total expenditure	7,669	15	8
Amount carried to net revenue account	8,387	10	2
	£16,057	5	10

Cr. Income.	£	s.	d.
By sale of current per meter	13,457	9	7
Sale under contracts	744	9	4
Public lighting	778	0	1
Rental of meters and other apparatus	392	2	3
Sale and repairs of lamps	449	15	5
Sale and repairs of other apparatus	235	9	2
	£16,057	5	10

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T.U.			1,249,226
Quantity sold	Public lamps	97,910	
	By contract	30,365	952,291
	Private consumers by meter	804,016	
Quantity used on works			15,405
Total quantity accounted for			947,696
Quantity not accounted for			301,350
Total maximum supply demanded (kilowatts)			780

Number of public lamps : 60 arcs, 255 8-c.p. incandescents.

FORTHCOMING EVENTS.

FRIDAY, NOV. 18.

Institution of Mechanical Engineers.—At 8 p.m., general meeting.

Junior Institution of Engineers.—At 8 p.m., Mr. W. H. Lindley will deliver his presidential address on "Municipal Engineering on the Continent."

North-East Coast Institution of Engineers and Shipbuilders.—General meeting.

Institution of Electrical Engineers (Manchester Section).—"Compensated Alternating-Current Generators," by Mr. M. Walker.

SATURDAY, NOV. 19.

Corps of Electrical Engineers (R.V.).—At 7.30 p.m., dinner at the Criterion.

Institution of Electrical Engineers (Leeds Section).—Visits to Messrs. W. T. Glover and Co.'s cable works and the Formby power station of the Lancashire and Yorkshire Railway.

MONDAY, NOV. 21.

Junior Institution of Engineers.—Visits to Dudley Port and Birmingham to inspect the central station of the South Staffordshire Mond Gas Company and the Nechells Gasworks of the Birmingham Corporation. Train leaves Euston at 9.20 a.m.

TUESDAY, NOV. 22.

Institution of Civil Engineers.—At 8 p.m., "Distribution of Electrical Energy," by Mr. J. F. C. Snell.

WEDNESDAY, NOV. 23.

Institution of Electrical Engineers (Birmingham Local Section).—At 7.30 p.m., the chairman (Dr. W. E. Sumpner) will deliver his address.

Society of Arts.—At 8 p.m., "The Systematic Promotion of British Trade," by Mr. B. H. Morgan.

THURSDAY, NOV. 24.

Institution of Electrical Engineers.—At 8 p.m., "Hydro-Dynamical and Electromagnetic Investigations regarding the Magnetic Flux Distribution in Toothed-Core Armatures," by H. S. Hele-Shaw, F.R.S., Alfred Hay, D.Sc., and P. H. Powell, M.Sc.

FRIDAY, NOV. 25.

Institution of Electrical Engineers (Manchester Students' Section).—At 7.30 p.m., "Electric Power in Machine Shops," by Mr. H. C. Jenkins.

SATURDAY, NOV. 26.

Glasgow Technical College.—At 7.30 p.m., "The Electrical Drive of Large Reversing Engines Working Intermittently," by Mr. M. Georgi.

December 1.—Annual dinner of the Institution of Electrical Engineer at the Hotel Cecil.

December 1.—Society of Arts, "Running Powers," by Mr. Stephen Sellon.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

MR. SWINBURNE'S REPORT ON CHELTENHAM.

This report contains much that is good, some that is bad, and a little rather indifferent. As regards the latter, we must not be dogmatical, because Mr. Swinburne is probably as justly entitled to his opinion as we are to ours—is just as likely to be correct—hence to tilt at him on this account would be dangerous. The good in the report needs no comment, but the bad must lead to discussion. Perhaps on one indifferent point we might venture a word: "Residents . . . not dependent on local prosperity." Is not this conclusion doubtful, and have not these residents been attracted because of the salubrity of the town, its varied attractions, and its low rates? The attractions are partly due to public works, and the lower rating is partly due to the increase in number of ratepayers, which increase again is due in some measure to the action of the authorities. Local prosperity really has much to do in attracting households with fixed incomes. A salubrious town, not prosperous, with high rates and no attractions, has few fixed-income households. On the contrary, such a town, very prosperous, with many attractions and low rates, has many fixed-income households, and the increased number further diminishes the rates per individual. The broad fact about Cheltenham is that its electricity supply has not been pecuniarily successful, that it has not furnished a profit, nor, indeed, covered its expenses. Mr. Swinburne, we are sorry to see, takes up a position in regard to accounts which we think wholly untenable and utterly fallacious. We shall meet with a direct negative the implied statement that a "local authority borrows at a low rate," the comparison, of course, being with a company. A real comparison is impossible because of the differing conditions. Many companies obtain capital and pay *no interest* whatever. The *rate of interest* at which a company gets its capital depends entirely upon the success of the company. Then is not the statement equally fallacious, that "an industrial concern provides capital for running at a loss during the first few years." We have seen a good many prospectuses, but we seldom see one that admits of a possible loss even on the first year's working, much more for several years. They mostly estimate for an immediate profit—small it may be, but still a profit; and to hear the excuses made at the annual meeting when such profit does not accrue would make an angel weep, and if, perchance, the profit should be a negative one—that, is a loss—no chairman would think of stating that the loss was provided for in the capital account. We are not referring to the period of construction. Investors know that profits cannot be earned before work is begun, but they do not expect to wait three or four years after work has commenced before getting a return for their investment. Highly speculative enterprises do not come within our purview. A speculation differs entirely from an ordinary investment in a humdrum concern. Further, we do not think Mr. Swinburne's reference to working capital is justified. The question of working capital depends altogether upon the concern. Some businesses require a very large working capital; others require a very small working capital, or none at all. Finally as regards these comments—otherwise they will become unwieldy—that blessed word "antiquation." It is a word imported into the discussions upon electrical matters, as if antiquation of machines electrical was something unique and applicable only to such machines. Can Mr. Swinburne or anybody else point out any general acceptance in the making of extra depreciation allowances for any class of machines hitherto used during the whole history of the world? Antiquation exists in

Digitized by Google

every class of machine wherein progress towards perfection is possible. Every good patent means antiquation of goodness knows what value of machinery, but the user of a boiler, or an engine, or a lift, or a machine does not antiquate it and scrap it, though by so doing he might possibly get something more efficient. No company can pursue the course of scrapping because of antiquation, and they do not. What happens is that the users of the older and, perhaps, less economical machines have to put up with diminished profits if products are sold at the same prices. The newer the mill or factory the more perfect the machinery, but the mill to be built five years hence will contain still more perfect machinery; but the former owner depreciates only in the usual way, not extra because of antiquation. However, this question will have to be thrashed out at greater length and more in detail elsewhere. As regards Mr. Swinburne's conclusions, they are correct, and may be summed up in the words that all commercial undertakings should be carried on with rigid regard to the known rules necessary for and leading to success.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

COST OF PRODUCTION AND MR. SIEMENS'S PRESIDENTIAL ADDRESS.

SIR,—At the present moment, when the future of our industries hangs in the balance, it is appropriate that Mr. Siemens in his presidential address should have drawn our attention to the fundamental factor which must govern such future. This factor is "cost of production," nothing else matters. Yet there is a reservation from a purely philosophic point of view.

Mr. Siemens is correct in saying that "the progress of civilisation is in proportion to the cheapening of articles of consumption." From a practical point of view—not the general, but the relative—cheapening of production is of importance to us. A man or a nation is concerned to produce an article more cheaply than another man or another nation. This sounds a prosaic reason for happiness, yet poets have expressed the same truth. Emerson says, "If a man can write a better book, preach a better sermon, or make a better mousetrap than his neighbour, though he build his house in the wood, the world will make a beaten path to his door!"

Mr. Siemens has not treated the subject from this comparative standpoint, and whilst we must thank our President for pointing out the important truth mentioned above, we regret that he has not brought it to its proper conclusion, and the result is that he does not set forth the true laws that govern cost of production, but leads us into by-paths that hide the truth. After introducing this subject, we, speaking as electrical producers, had the right to expect an answer this question: Is the English electrical industry capable of producing as cheaply or cheaper than its Continental or American rivals? If Mr. Siemens thinks the answer should be in the affirmative, then we would ask, "Why are millions worth of electrical machinery imported from abroad?" If the answer should be in the negative, then we wish to hear from the presidential chair the reasons and the remedy.

We cannot deduce from Mr. Siemens's address a decided opinion, but from its general pessimistic tone we must surmise that English industries are not capable of producing that cheapness which he considers essential, and he makes this concluding remark, "It is hopeless to endeavour to re-establish our former monopoly." Surely Mr. Siemens said nothing that should lead him to give such desponding advice, and we, as a firm engaged in producing industries, wish to raise a protest against such a melancholy pronouncement, which if believed in must inevitably have the effect of striking terror into the hearts of English manufacturers.

Surely a country that not so long ago could make "mousetraps" better than any other country can hope to do so again! England has a healthy climate, an unrivalled geographical position, a good soil, great mineral resources, and an industrious population. Surely if we at present do not produce as well and cheaply as other countries, whose natural resources are worse than ours, there must be a reason for it of an exceptional character.

Mr. Siemens somehow endeavours to blame somebody—our workmen and trade unions are accused of restricting output, and thus increasing cost of production. Our patent laws and the "want of the metric system" are mentioned. I hold that these and similar reasons are secondary, and would disappear if the primary reason were removed. Cheapness of production nowadays depends upon the manufacture of large quantities, and to enable a large output the first essential is demand—that is, customers and their orders.

We do not at present manufacture in England as cheaply as our rivals abroad, because our factories are not as large and our output not as continuous. In other words, our rivals have a larger market for their products. This larger market is given to foreign manufacturers by the help of their and our Governments. Their Government gives them security by means of custom duties of their home market; our Government gratuitously places at their disposal our own home markets. Thus we in England are deprived of that reasonable security so necessary to procure large output and demand which our rivals possess.

It is evident that Mr. Siemens, whilst telling us in dismal language that we have lost the faculty of cheap production, does not give us the true reason, which is lesser demand than that enjoyed by our rivals. It is true that had he come to this very obvious conclusion, he would have had to touch upon the fiscal question—a contingency which he deprecates—but the question of cost of production is so intimately connected with the trading systems of the world, that it would have been better not to dwell on the subject at all than to be diffident in attacking its logical conclusions.—Yours, etc.,

G. BYNG.

GERMAN TELEPHONES.

SIR,—I notice in your issue of the 11th inst. you devote a leading article to the question of "Why, in certain telephone work for the Richmond Guardians, German telephones were adopted instead of British-made instruments," and that a letter also appears in your correspondence column on the same subject. You suggest that there may be several reasons, but confine yourself to the one which you think the most charitable. May I suggest one or two other reasons, and at the same time, in the spirit of the two lines of poetry heading your correspondence column, ask you to spare space therein for the publication of same?

First, then, I understand that the German make of telephone was specified by the architect. Now, I take it an architect is a person selected on account of his superior knowledge of certain matters to advise his clients according to his experience and opinions, and prepare specifications based upon such advice, with a view to ensuring that his clients get the best value for their money. In specifying the particular type of German-made telephones, he doubtless had this fact well in his mind, and specified that which his experience found to be the most reliable. Obviously, therefore, an architect is quite an unnecessary extravagance if his opinion is not to be accepted as paramount, and if any contractor with an imaginary grievance, or for other reasons, is allowed to walk round the specification, the services of the architect could be dispensed with, and public bodies might as well throw open their work to contractors, and invite them to send in estimates and specifications *ad lib.*—with what results can be left to the imagination.

Secondly, I note that there are already some British and German made telephones in use at Richmond, the former being of the same make as those which were offered as an alternative by the "Disappointed Contractor." I suggest the probability, Sir (with bated breath, and no thought of treason), that the German-made telephones may have proved the most satisfactory when working alongside the British-made article.

Thirdly, it is more than probable that some of the types

Digitized by Google

of instruments specified as most suitable were such as are not made by British firms.

Beyond these points, I notice that the "Disappointed Contractor's" tender for British-made telephones was about 10 per cent. lower than for German make. Since the wiring of the job either with English or German made instruments could not possibly vary, the logical conclusion is that he could not buy the latter so cheaply by 10 per cent. as he could the former. This fact is quite antagonistic to the general opinion that German goods are dumped down in this country and sold at ruinously low prices, in competition with British-made goods. Here is a case where, according to the "Disappointed Contractor's" showing, the German goods are 10 per cent. dearer in price, and yet are preferred to British make.

There must be something distinctly superior about the German-made telephones to account for this, and the architect is consequently justified in specifying same. If my deductions are incorrect or illogical, then there must be some other reason why the "Disappointed Contractor" can quote 10 per cent. lower for British-made than for German-made telephones. These reasons would, of course, be best known to himself, but if he were so disinterestedly anxious to further the interest of the British industry, I do not doubt that many of his fellow-contractors would thank him to tell them how he manages it. "Puzzled" might think it out.—Yours, etc., ENGLISHMAN.

Nov. 16, 1904.

BASTIAN METER COMPANY.

SIR,—It has come to my knowledge that a rumour has gained considerable currency to the effect that I have terminated my connection with the above company, and I should esteem it a great favour if you will grant me space in your columns to give this rumour an emphatic denial, as it is calculated to do me and my business serious damage. As a matter of fact, I and my relatives have considerably increased our holdings in the company during the last few months, and although I have nominally resigned the managing directorship, nevertheless I take precisely the same active interest in the management as heretofore.—Yours, etc., C. ORME BASTIAN.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

XIV.—ON SUBORDINATION.

MY DEAR YOUNG 'UN,—I am now about to address you for the benefit of your health and the good of your soul, so to speak. If anything I may say appears to you to be unjust or harsh, you are at liberty to reply in your next, provided that you are polite.

I have noticed in your letters a growing tendency to carp at your employer. He seems, judging from your epistles, to be everlastingly in one of three conditions—he is either doing well that which he ought never to be doing at all, or he is doing badly that which he ought to be doing well, or he is not doing at all that which he ought to be going for baldheaded. Consequently I have been keeping an anxious eye on the share market, for the reason that I am to a certain small extent financially interested in your firm. I am glad to say, however, that up to the present there has been no panic on the Stock Exchange about the position of your concern, the manufactures of the company bear a good name, and I am therefore impelled to the opinion that you have been raising the "Wolf" cry.

Now, to a man of your decent disposition and average intelligence, it does not need to be elaborately demonstrated that to have the reputation of being an unfair critic is about the most unfortunate character you can get. Most fellows of the better sort have an instinct for equity, and I have known cases where a man has yielded a point or two that he believed to belong to him rather than run the risk of falling into unfairness.

It is puerile to take up the position that master and man are natural enemies, and fair game for each other's venomous criticism. When I was a boy at school I imagined that I was doing a great and glorious thing in shielding a schoolmate from well-deserved castigation. The argument, so far as I can recollect it, was: The master is bigger than us, therefore he can, and will, thrash; therefore he is our enemy; therefore we must exercise our utmost ingenuity and, if necessary, suffer tortures, to make his life a misery. And we did it. And precious little fools we were. A good many workmen reason on the same lines with respect to their employer, only as they daren't play monkey-tricks for fear of losing their job they take it out in criticism. It is no use saying to this type of malcontent, "Put yourself in his place," because he knows he will never have a chance of getting there. Consequently he can make foolish utterances, with the knowledge that he will never have to eat them afterwards. If you analyse the shop criticisms you hear, you will deduce two things; first, that certain criticisms become general property, each man saying that thing because it is fashionable, and each one believing it because everybody else says it; second, that any man bringing a fresh criticism into the market goes about for the rest of the day with the swagger of a new recruit on his first evening out, to the admiration of all beholders. If you can preserve your independence of thought to the extent of detaching yourself from an opinion that is generally accepted as an axiom unless it appeals directly to your own reason, you will see that many shop criticisms are short-sighted and one-sided; if you can keep your natural fairness intact through the rasping influences of shop-life, you will understand there is no glory in picking holes in a man's coat unless some tangible good can come of the ventilating process.

The boss of a works has a very difficult job. He has not merely to fashion his own work in all its details with the aim of making it successful, but he has to originate master-thoughts for all the intelligences under him. Detail thought is fairly simple. The workman who cannot think out the details of the job he is on is an idiot, and should be given an outside berth with no screw attached. But master-thinking is different. Phil May was a genius at line-drawing. He could express as much with three curves and a wiggle as most men could get with a maze of cross-hatching and stippling. His method was to get his picture down somehow, and then to eliminate, line by line, all unnecessary strokes till only the master-lines remained. The picture, splendid in simplicity, was then presented for the beholder to fill in his own mental conception of light and shade. The works manager, if he manages at all, is the master-line man. He puts in the sweeping strokes of policy. His is the sphere of broad effects. You are given a little bit of the general picture to fill in with light and shade to the best of your ability. You are a subordinate, but you are as good a man as your boss if, and only if, you perform your function as well as he does his. If you jab in your finishing touches in a slipshod manner under the conviction that the whole picture is a mess, the probability is that your part of the show will be conspicuous by its wretched execution. The man has not been invented yet who can at one and the same time growl at the general scheme and put in good work on the part entrusted to him. On the other hand, a good morsel of detail work may possibly save a general scheme from wreck.

Another thing that wants guarding against is selfishness. Don't try to run the show if someone else is paid to do it. If you are capable and the boss isn't, the surest way of convincing the shareholders that you are the better man is to make the excellence of your particular department scintillate against the general background of mediocrity provided by your chief. If you are really superior to your boss it will not be long before other people are in the know besides yourself, provided that you express the state of the case in works rather than words. I understand that the truth about the Russian disaster on the Yalu was that one of the subordinate generals thought he knew a lot better than his commander-in-chief. He pushed his own success and crumpled up the entire army. Consequently he got himself disliked. Don't you!

As a final exhortation, let me implore you, if you really must quarrel and criticise and kick because of your employer, to make a confidant of the household cat. Previously lighting your pipe, esconce yourself in front of the fire in your private sitting-room and induce the cat to repose on the hearthrug. Produce that state of satisfaction in the

Digitized by Google

beast which is indicated by loud rumbling noises, either by stroking it, addressing it in endearing accents, or other blandishments. Carefully note that the door and windows are completely closed, and then pour out your sorrows to the cat. Let yourself go—let there be no reserve; consider the cat as your wife or your familiar demon. The animal will probably turn its greenish eyes upon you with silent sympathy. It may even be moved to rub its head against your trouser-leg or to leap upon your lap. However this may be, you may be perfectly certain that it will not repeat what you have said. And this is the greatest qualification that a cat can have, from the point of view of a subordinate like yourself, whose ideas are divergent from and superior to those of his boss. Anyway, don't write to me again indicating that you can see further and know better than your chief, because I shall just pitch your letter into the fire.—Yours, THE OLD 'UN.

ELECTRICITY IN FACTORIES.

PROPOSED NEW REGULATIONS.

In our issue for Oct. 21, on p. 602, we published a draft received from the Home Office of some proposed regulations dealing with the use of electricity in factories. Before these come into force an enquiry will be held before a committee, and it is extremely desirable that anyone having objections to the regulations should bring forward the same in good time. That some such regulations are good for the whole industry we have no doubt, but it is equally important that the wording actually adopted should be such that clauses do not prevent the spread of electrical driving in factories, nor hamper developments in the application of electricity to factory work generally. We have carefully gone through the proposed regulations and have talked the matter over with a number of firms interested. The following are some of the amendments which have been suggested, and we publish them in order that others may again look through the regulations and see whether these amendments could not themselves be improved upon before the committee meets to hear evidence. These amendments are:

(*a*) *Clause* 1.—The totally enclosing of wires in strong metal casings is objected to on the grounds of (*b*) inaccessibility of conductors; difficulty in maintaining satisfactory insulation resistance between conductors and earth; in totally enclosed metal tubing, owing to the condensation of moisture in such tubing; difficulty of inspecting the condition of conductors when in service; difficulty of localisation of faults and the remedying of same, due to the inaccessibility of conductors; increased first cost. It is suggested that cables supported on insulators, spaced a suitable distance apart, are readily accessible and enable the insulation resistance to be maintained at its maximum value. It is suggested that Clause 1 be amended as follows: (*c*) "All wires in connection with the supply shall be so arranged that there shall be a minimum danger from shock or fire. Where readily accessible, the wires shall be completely enclosed in strong metal or other approved casing."

(*a*) *Clause* 2—(*b*) It is suggested that where suitably-designed automatic circuit breakers are used it is unnecessary to use switches in series with them, as an automatic circuit breaker is an equally reliable device to a switch, and, in general, is better adapted to open a circuit under emergency conditions. The addition of a switch under the circumstances increases the first cost of the installation without increasing the safety of the arrangement. It is, therefore, suggested that this clause be amended as follows: (*c*) "All mains and branch circuits should be protected by switches and fuses, or by automatic circuit breakers. Where circuit breakers are used on one pole only they shall be fitted either with a free handle device, or equivalent, to prevent the possibility of a circuit breaker being held in on a short-circuit"

(*a*) *Clause* 3.—From the word "provided" on the seventh line to the end, involves the provision of a separate switch for single arc lamps, even when connected in series, and prevents the control of such lamps in groups when the pressure exceeds 250 volts from earth. (*b*) As various manufacturers are already supplied, and more will undoubtedly be supplied in the near future from a system of power supply which is also furnishing power for traction purposes at 500 volts, and on which systems the negative pole will consequently be earthed, in the case of groups of arc lamps or other similar devices in series between the conductors there will be 500 volts pressure from earth. It is suggested that the extra cost and complication of a separate switch to each lamp, owing to the grouping of lamps connected across a 500-volt circuit, besides the extra cost involved in the wiring, is unnecessary. It is, therefore, recommended that this clause be amended from the word "provided" on the seventh line to the end as follows: (*c*) "That where arc lamps are connected in series across conductors on a circuit, the pressure of which cannot exceed 650 volts from earth, it shall be sufficient if one double-pole switch, conveniently placed, be provided for each such series of arc lamps."

(*a*) *Clause* 5—As regards the words "all metal holders for incandescent lamps." (*b*) It is suggested that this clause would increase the cost of the installation of electric lighting in factories in many cases to a prohibitive extent, and would entirely prohibit the use of plain pendant fittings in positions for which they are eminently suited. The provision of earth-wires for the metal parts of all such fittings, even if practicable, would be a very serious item. Further, in the event of the lighting being connected to a three-wire system, with a grounded neutral and an earth occurring on to the metalwork of the fitting, the full potential between the outers of the three-wire system would exist between the fitting and earth. The following amendment is therefore suggested: (*c*) Omission of the words, "All metal holders for incandescent lamps." The amended clause will then read: "The frames of all motors and metal casings of all wires, switches, and fuses and cut-outs shall be efficiently connected to earth."

(*a*) *Clause* 6.—While this apparently refers to apparatus under the control of public supply authorities, is it intended in Clause 6, paragraph (*a*), that the provision of a fuse in the neutral is prohibited only in so far as the service lines are concerned, and that fuses may be used on both poles of branch distribution circuits, one pole of which is connected to the neutral service lines. This applies particularly to lighting installations which are supplied from one outer and the neutral of a three-wire system.

METHODS OF CABLE-LAYING.

BY LEONARD ANDREWS, A.M.I.C.E., M.I.E.E.

If there is one subject more than any other upon which engineers hold widely different opinions, it probably is the much-discussed question of laying electric light mains. Some pin their faith to armoured cables laid directly in the ground, others prefer plain lead-covered cables laid in troughs filled with bitumen, whilst many others will have nothing but some form of drawn-in system. Each particular system has its peculiar advantages, and it is impossible to obtain any system in which all the advantages of other systems are combined. The advantages and disadvantages of some of the systems that have been most largely used are summarised below:

ARMOURED CABLES LAID DIRECT IN GROUND.

Advantages.—For open country work, where there are no gas and water pipes, armoured cable can be simply and cheaply laid directly in the trench by merely unwinding the cable drum over the trench, thus avoiding all risks of straining the cable. This advantage disappears if the cable has to be threaded under the many gas and water services that exist in most streets.
